Message du Président du comité du programme

Ve Conférence internationale sur le SIDA
SOUS LE SIGNE DE LA SOLIDARITÉ

En tant que président du Comité du programme de la Ve Conférence internationale sur le SIDA, je tiens d'abord à vous remercier chaleureusement d'avoir accepté notre invitation. Votre présence, ainsi que celle de vos nombreux collègues, est un témoignage éloquent de la solidarité qui unit tous les participants de cette rencontre exceptionnelle.

Il nous est permis, au-delà des mots, de croire que ce congrès sortira vraiment de l'ordinaire. D'abord, par son ampleur : plus de 10 000 délégués, 1 000 représentants des médias et 1 000 représentants de compagnies et d'organisations. Mais surtout, par la philosophie profondément humaniste qui l'animera.

L'observateur qui aura suivi attentivement, depuis Atlanta en 1985, la série de conférences internationales sur le SIDA, aura noté à quel point ces rencontres se sont progressivement décloisonnées. À l'origine, on s'en souviendra, la Conférence abordait quasi exclusivement des thèmes biomédicaux. Mais graduellement, les chercheurs scientifiques ont dû se rendre à l'évidence : le SIDA n'était pas seulement un problème médical, mais aussi un drame humain.

Bien sûr, nous savons tous que la solution ultime verra éventuellement le jour dans un laboratoire. Mais entre-temps, qu'est-ce que le virologue ou le microbiologiste peuvent proposer au sidéen et à ses proches pour alléger leur fardeau? Pour les aider à lutter contre l'ignorance et l'intolérance qui, chaque jour, se font plus présents? Nos laboratoires sont des lieux d'espoir; notre conscience nous interdit de les laisser se transformer en ghettos. Devant les extrémismes qui pointent à l'horizon, il est de notre devoir à tous de contribuer à l'élargissement et à l'approfondissement de l'étude du SIDA. Agir autrement serait inconscient, voire même cruel pour des millions de gens qui tournent vers nous des regards chargés d'espoir.

Le Congrès de Montréal innove donc en présentant officiellement une perspective multidisciplinaire, que résume bien son thème : "Le SIDA : défi scientifique et social." Le programme de la rencontre reflète précisément cette approche intégrée, puisque 30 % des séances toucheront les divers aspects sociaux du problème. Dilution du contenu biomédical? Aucune crainte n'est permise à ce sujet : dans les seuls domaines de l'épidémiologie, des aspects cliniques et de la recherche fondamentale, on compte plus d'une centaine de séances et près de 550 conférenciers—plus que toute autre rencontre auparavant. Miroir de cette nouvelle approche, le recueil des résumés vous propose une somme de 5 539 textes qui s'attaquent tant aux dimensions médicales que sociales du SIDA.

Plus humaine, donc, l'approche. Et à la fois plus internationaliste. Car avouons-le, il restait à la série de conférences internationales sur le SIDA à véritablement s'internationaliser. Avec le recul du temps, il nous apparaît évident que le Tiers Monde n'a peut-être pas occupé toute la place qui lui revenait lors des précédentes rencontres. Situation paradoxale quand on sait que la pandémie a des conséquences particulièrement graves dans le Tiers Monde : les plus récentes statistiques font état d'un taux d'infection atteignant jusqu'à 20 % chez la population hétérosexuelle de certaines grandes villes.

Les organisateurs de la conférence de Montréal n'ont pas hésité : ils ont tout mis en oeuvre pour accroître la participation du Tiers Monde. En consultant des chercheurs des pays en voie de développement sur les questions d'organisation. En commanditant des conférences préparatoires en Afrique, en Asie et en Amérique latine pour déterminer les attentes des chercheurs locaux face à l'événement. Le Canada, par l'entremise de l'Agence canadienne de développement international (ACDI) et de différents organismes dans d'autres pays occidentaux, a aussi apporté une assistance financière pour assurer cette participation.

Enfin, nous avons veillé à ce que la Conférence demeure un instrument privilégié pour sensibiliser les populations, les décideurs et les pouvoirs publics du monde entier. La Conférence de Montréal utilise abondamment la technologie audiovisuelle et des expositions artistiques à des fins didactiques. Elle innove aussi en facilitant une participation hors murs du grand public. Toujours dans cet esprit d'ouverture sur le monde, les organisateurs ont établi que les langues officielles de la Conférence seront l'anglais et le français. Des traductions simultanées dans ces deux langues sont offertes en tout temps, ainsi qu'en espagnol aux séances plénières.

Dans la foulée des premières rencontres, la Conférence de Montréal est elle aussi une tribune internationale favorisant l'échange d'information. Mais plus encore, nous avons voulu qu'elle se signale par une convergence sans précédent de toutes les énergies et compétences disponibles. À l'heure de l'interdépendance planétaire, au-delà des barrières professionnelles et des divergences de toute nature, la solidarité de la communauté internationale face au problème du SIDA s'impose plus que jamais. Ce n'est qu'à ce prix que des millions de gens démunis pourront légitimement entretenir l'un des biens les plus précieux qu'il leur reste : l'espoir.

Richard A. Morisset, M.D.
Président du Comité du programme de la V^{e} Conférence internationale sur le SIDA

Message From the Programme Committee Chairman

V International Conference on AIDS
UNDER THE BANNER OF SOLIDARITY

As Chairman of the Program Committee for the V International Conference on AIDS, first let me cordially thank you for accepting our invitation. Your presence here, alongside your numerous colleagues, attests eloquently to the solidarity binding everyone attending this exceptional meeting.

For we have solid reason to believe that this conference will really be an extraordinary one. First, because of its scope: over 10,000 delegates, 1,000 media representatives and 1,000 corporate and organizational delegates. But above all, by the profoundly humanistic philosophy guiding it.

Anyone who has kept a close watch on the series of International Conferences on AIDS that began in Atlanta in 1985 will have noticed how these encounters have gradually opened up. Originally, you will recall, the meetings dealt almost exclusively with biomedical topics. Yet scientists soon had to admit that AIDS is not simply a medical problem, but also a human drama.

Naturally, we all know that the ultimate solution will eventually come to light in a laboratory. But meanwhile, what can the virologist or microbiologist offer an AIDS victim and his or her loved ones to ease their burden? To help them combat the ignorance and intolerance they face, which are growing day by day? Our laboratories are realms of hope; our conscience forbids us from turning them into ghettos. Facing the extremists looming to the horizon, we all have a duty to help broaden and deepen research into AIDS. To act in any other way would be unconscionable, if not cruel to the millions of people looking to us with profound hope.

The Montreal Conference represents an innovation in that it officially presents a multidisciplinary view neatly summarized in its theme: "AIDS: A Scientific and Social Challenge." The program for this meeting accurately reflects this integrated approach, since 30% of the sessions will deal with various social aspects of the problem. Will this dilute its biomedical content? That need scarcely be feared: in the fields of epidemiology, clinical aspects and basic research alone, there will be over 100 sessions and almost 550 speakers—more than at any previous conference. Mirroring our new approach, the collected abstracts cover a total of 5,539 papers that tackle both the medical and social dimensions of AIDS.

Definitely a more human approach. And at the same time a more international one. For we must admit that our series of international conferences on AIDS have yet had to become genuinely international. With the passage of time, it became clear to us that the Third World may not have been playing its full role at past meetings. This is paradoxical, since we know that the pandemic is having especially serious consequences in the Third World: the most recent statistics indicate an infection rate covering almost 20% of the heterosexual population in some major cities.

The organizers of the Montreal Conference have made every effort to increase Third World participation. They have consulted scientists from developing countries on organizational matters. They have sponsored preparatory conferences in Africa, Asia and Latin America to determine what local scientists expect from the event. Canada, through the Canadian International Development Agency (CIDA) and various organizations in other western countries, has also provided financial assistance to ensure Third World participation.

Finally, we saw to it that this Conference will be a special means of raising the consciousness of the general public, decisionmakers and public authorities around the world. The Montreal Conference will use a wealth of audiovisual technology and art exhibits for educational purposes. It is also innovating by making it easier for the general public to participate extramurally. In this same spirit of openness to the world, the organizers have decided that the Conference's official languages will be English and French. Simultaneous translation into either language will be available at all times, along with Spanish at the plenary sessions.

Like its predecessors, the Montreal Conference is an international forum promoting the exchange of information. But even more, we wanted it to signal an unprecedented convergence of all the available energy and skills. In the era of the global village, leaving behind professional barriers and differences of every kind, the international community's solidarity in confronting the problem of AIDS is more vital than ever. It is at this price alone that millions of people can legitimately nourish one of their most valuable remaining possessions: hope.

Richard A. Morisset, M.D.

H. **The Economic Impact of AIDS**
- Macroeconomic impact in developing countries, 404 AB 1034

Mercredi 7 juin

8 h 30 à 10 h 30

« État de la question » — Plénière
Palais des Congrès 407 ABC *

11 h à 17 h 30

Présentations audiovisuelles — Centre de conférences Guy-Favreau

11 h à 12 h 30 — page

A. **Épidémiologie et santé publique**
- Transmission du VIH dans le milieu des soins de la santé, 407 A 63
- (Table ronde) Transmission hétérosexuelle, 408 BC 64

B. **Aspects cliniques**
- Pharmacologie et toxicité de l'AZT, 401 ABC 203
- Traitement : thrombocytopénie, 403 ABC 204
- (Colloque) Qualité des soins offerts aux personnes atteintes du SIDA, 407 B 205

C. **Recherche fondamentale (biomédicale)**
- (Colloque) Gènes régulateurs et diversité génomique virale, 407 C 524
- Éléments de base en immunologie (partie 1), 408 A 525
- Biologie moléculaire (partie 2), 410 ABC 526

D. **Le SIDA et l'individu**
- Les femmes, 409 ABC 704

E. **Le SIDA, la société et le comportement**
- Rôle des ONG dans la lutte mondiale contre le SIDA, 411 A ... 825
- La lutte communautaire contre le SIDA dans les années 1990, 411 B 827

F. **Droit et éthique**
- (Colloque) Recherche de traitements et de vaccins, 411 C 950

G. **Implications internationales**
- Le VIH en pédiatrie, 406 A 982
- (Colloque) Infections parasitaires tropicales : impact du VIH, 406 BC 983

H. **Répercussions économiques**
- Rôle des assurances, 404 AB 1035

Sessions d'affichage — page

A. **Épidémiologie et santé publique** 120
B. **Apects cliniques** 352
C. **Recherche fondamentale (biomédicale)** 592

G. **Implications internationales**
- Perspectives mondiales, 406 A 984
- Transmission hétérosexuelle et rôle des MTS, 406 BC 985

H. **Répercussions économiques du SIDA**
- Financement et assurances, 404 AB 1036

16 h à 17 h 30 — page

A. **Épidémiologie et santé publique**
- L'annonce aux partenaires, 407 A 67
- Test de dépistage du VIH/Questions en matière de politiques et de programmes, 408 BC 68

B. **Aspects cliniques**
- Infections associées au SIDA, 401 ABC 209
- Atteintes neuropsychiatriques, 403 ABC 210
- (Colloque) Essais cliniques : points de vue des « acteurs », 407 B . 211

C. **Recherche fondamentale (biomédicale)**
- Virologie (partie 3), 407 C 530
- Éléments de base en immunologie, 408 A 531
- Modèles animaux (partie 3), 410 ABC 532

D. **Le SIDA et l'individu**
- (Colloque) Les femmes dans les pays industrialisés : Questions et options, 409 ABC 706

E. **Le SIDA, la société et le comportement**
- Services de pastorale, 411 B 830

F. **Droit et éthique**
- (Colloque) Cœrcition ou volontarisme ? Analyse critique internationale, 411 C 954

G. **Implications internationales**
- Prévalence (partie 3), 406 A 986
- (Atelier) Atelier régional : Afrique occidentale, 406 BC 987
- (Colloque) Déplacements internationaux et SIDA, 411 A 988

H. **Répercussions économiques du SIDA**
- Méthodologie des analyses de coûts, 404 AB 1037

Wednesday, June 7

8:30 - 10:30

"State-Of-The-Art" — Plenary session
Palais des Congrès 407 ABC*

11:00 - 17:30

Audiovisual Presentations — Guy-Favreau Conference Centre

11:00 - 12:30

page

A. **Epidemiology and Public Health**
- HIV transmission in the health care setting, 407 A 63
- (Round table) Heterosexual transmission, 408 BC 64

B. **Clinical Aspects of AIDS**
- AZT Pharmacology and toxicity, 401 ABC 203
- Therapy: thrombocytopenia, 403 ABC 204
- (Symposium) Quality of care for patients with AIDS, 407 B ... 205

C. **Basic Research (Biomedical)**
- (Symposium) Regulatory genes and viral genomic diversity, 407 C 524
- Basic immunology, 408 A 525
- Molecular biology (Part 2), 410 ABC 526

D. **AIDS and the Individual**
- Women, 409 ABC 704

E. **AIDS, Society and Behaviour**
- The role of NGO in the global response to AIDS, 411 A 825
- The community-based response to AIDS into the 1990s, 411 B . 827

F. **Ethics and Law**
- (Symposium) Research for treatments and vaccines, 411 C 950

G. **International Issues**
- HIV in pediatrics, 406 A 982
- (Symposium) Tropical diseases: the impact of HIV, 406 BC ... 983

H. **The Economic Impact of AIDS**
- The role of insurance, 404 AB 1035

Poster Sessions

Vendredi 9 juin

8 h 30 à 10 h 30

« Perspectives d'avenir » — Plénière
Palais des Congrès 407 ABC *

Cérémonie de clôture

Président
Ivan Head
Président de la Conférence
Président du Centre de recherches pour le développement international
Canada

Conférenciers
L'Honorable Perrin Beatty
Ministre de Santé et Bien-être social
Canada

Mohammed Abdelmoumène
Directeur général adjoint
Organisation mondiale de la santé
Suisse

John Ziegler
Président
VI^e Conférence internationale sur le SIDA
États-Unis

Lars Olof Kallings
Président
Société internationale sur le SIDA
Ministère de la Santé et des Affaires sociales
Suède

Message de
Danielle Mitterrand
Présidente, Fondation France Libertés

Randy Shilts
Correspondant national
San Francisco Chronicle
États-Unis

Friday June 9

8:30 - 10:30

"Future Prospects" — Plenary session
Palais des Congrès 407 ABC

Closing Ceremony

Chairman
Ivan Head
Conference Chairman
President, International Development Research Centre
Canada

Plenary Speakers
The Honourable Perrin Beatty
Minister of Health and Welfare
Canada

Mohammed Abdelmoumene
Deputy Director-General
World Health Organization
Switzerland

John Ziegler
Chairman
VI International Conference on AIDS
United States

Lars Olof Kallings
President
International AIDS Society
Ministry of Health and Social Affairs
Sweden

Message from
Danielle Mitterrand
President
Fondation France Libertés

Randy Shilts
National Correpondent
San Francisco Chronicle

Monday June 5

Nouvelles Perspectives

Présidents :
Maureen Law
Sous-Ministre
Santé et Bien-être social Canada

Donald deGagné
Directeur, Vancouver Persons with AIDS Society
Canada

Conférenciers :
June Callwood
Journaliste
Globe & Mail
Canada

Albert Jacquard
Professeur à l'Université de Genève
Chef du service de génétique
Institut national d'études démographiques
France

Mechai Viravaidya
Fondateur
Population and Community Development Association
Thaïlande

Stephen Joseph
Commissaire de la santé
Ville de New York
États-Unis

David Suzuki
Scientifique/Journaliste
Département de zoologie
University of British Columbia
Canada

New Perspectives

Chairpersons:
Maureen Law
Deputy Minister
Health and Welfare Canada

Donald deGagné
Director
Vancouver Persons with AIDS Society
Canada

Plenary speakers:
June Callwood
Columnist
Globe & Mail
Canada

Albert Jacquard
Professor, University of Geneva
Chief, Genetic Services
Institut national d'études démographiques
France

Mechai Viravaidya
Founder
Population and Community Development Association
Thailand

Stephen Joseph
Commissioner of Health
New York City
U.S.A.

David Suzuki
Scientist/Broadcaster
Department of Zoology
University of British Columbia
Canada

Le mardi
6 juin

Tuesday
June 6

État de la Question

Président :
James O. Mason
Secrétaire adjoint de la santé des États-Unis

Conférenciers :
Progrès en gestion clinique du SIDA et de l'infection par le VIH dans le monde industrialisé
Ian Weller
Directeur d'études
Faculté de médecine génito-urinaire, University College & Middlesex School of Medicine
Angleterre

Difficultés et obstacles à la gestion optimale du SIDA et de l'infection par le VIH dans le monde en développement
N'Galy Bosenge
Directeur
Comité national du programme de lutte contre le SIDA au Zaïre

La perspective communautaire—questions confrontant les personnes ayant le SIDA et infectées par le VIH dans le monde en développement
Daniel Defert
Président
AIDES Féderation nationale
France

Humanité : les mesures pour une éthique sur le SIDA
David J. Roy
Directeur
Centre de bioéthique
Institut de recherche clinique de Montréal
Québec, Canada

La dynamique de la transmission du VIH : le rôle des modèles dans l'interprétation, la prédiction et l'évaluation des paramètres
Roy M. Anderson
Professeur
Imperial College of Science and Technology
Angleterre

State-of-the Art

Chairperson:
James O. Mason
Assistant Secretary for Health of the United States

M.A.0.1

HIV SEROCONVERSION RATE IN A SERIALLY-TESTED POPULATION OF YOUNG ADULTS IN THE UNITED STATES (1987-1988).

McNeil, John*; Wann, F.**; Burke D.*; Brundage, J.*
*Walter Reed Army Institute of Research, Washington DC, USA; **SRA Technologies, Alexandria Virginia, USA.

Objective. To describe the rate of, and demographic characteristics associated with, HIV seroconversion within a large population of US citizens who are serially-tested for HIV antibody (HIV-Ab).

Methods. Civilian applicants for military service and all soldiers on active duty are routinely tested for HIV-Ab. Current policy stipulates repeat testing at least biennially. A total of 76,787 people tested negative for HIV-Ab on or after November 1, 1987 and were subsequently retested before November 1, 1988. The average time between tests was 7.2 months. An incident case is defined as someone who tested negative on the first test (EIA- or WB-) and positive on the subsequent test (WB + in duplicate).

Results. Twenty-nine seroconversions occurred over the observed period resulting in an annual incidence rate (IR) of 0.63/1000 (95% Poisson CI: 0.42-0.90). Direct rate adjustment by age to the standard US Army population resulted in an annual IR of 0.74/1000. Seroconversion risk was associated with minority ethnicity, age between 20-30 years, male gender, and being unmarried. Investigation of specific behavioral risk factors for seroconversion is in progress.

Conclusion. To the best of our knowledge, military testing programs represent the only opportunity to obtain a US population-based estimate of incident seroconversion. Using the method described above, the annual rate of new HIV infections within the Army has remained stable (0.74/1000) during interval years 1985-86, 1986-87, and 1987-88, and currently results in about 550 new HIV infections per year in this cohort of presumably low-risk young adults.

M.A.0.3

EPIDEMIOLOGY OF HIV INFECTION IN ACTIVE DUTY ARMY MEN AT NO IDENTIFIED RISK (NIR)

Renzullo, Philip*; McNeil, J.*; Bunin, J.**; and Brundage, J.* .
*Walter Reed Army Institute of Research, Washington, DC, USA; **AIDS Program, National Institute for Allergy and Infectious Diseases, Rockville, MD, USA.

Objective. To investigate risk factors for HIV infection among HIV-Ab positive male soldiers at no identified risk (NIR) for HIV infection and randomly selected HIV-Ab negative controls.

Methods. A large proportion of HIV-Ab positive male soldiers do not disclose histories of homosexuality/bisexuality, IV drug use, hemophilia, blood transfusions, or sexual activity with persons at risk for HIV infection. A case-control risk factor study was conducted with HIV-Ab positive soldiers and matched HIV-Ab negative controls. Subjects consented to a voluntary, anonymous and confidential survey of demographics, medical history, drug use, sexual history, and other behaviors associated with HIV infection. Civilian interviewers were blinded to the HIV-Ab status of each participant.

Results. Twenty (76.9%) of 26 cases and 9 (12.2%) of 74 controls reported engaging in behaviors associated with increased risk of HIV infection. Conditional logistic regression revealed significant risk of HIV infection was independently associated with engaging in sex with men (adjusted Odds Ratio (OR)=44.7, p=.03), engaging in sex with IV drug users, (OR=27.8, p=.02), being unmarried (OR=14.5, p=.02), and engaging in sex that caused one or both partners to bleed (OR=8.6, p=.04).

Conclusion. Results suggest that NIRs in the Army can be reclassified into traditional risk categories at about the same rate as in civilian studies. Study designs that are not only confidential, but also anonymous and interviewer-blinded, can improve the quality of risk factor assessments in both civilian and military individuals who perceive that divulging risk factor information can be potentially incriminating.

M.A.0.5

MEASURING LEVELS AND TRENDS OF HIV INFECTION IN THE GENERAL POPULATION BY MONITORING HIV SEROPREVALENCE IN PRIMARY CARE OUTPATIENTS

Petersen, Lyle*; Dondero T.*; Engel R.** and Herring N.**
*Centers for Disease Control, Atlanta, Georgia, USA, **Damon Clinical Laboratories, Needham Heights, Massachusettes, USA

Objective. To monitor nationwide levels and trends of HIV infection by surveillance of an accessible segment of the general population not selected on the basis of HIV risk factors and not self-selected.

Methods. On January 3, 1989, we began a blinded HIV seroprevalence survey using 100,000 outpatient blood specimens submitted annually by 15,000 primary care physicians to a national commercial laboratory for complete blood count (CBC) or hematocrit determination. CBC or hematocrit specimens are mostly drawn during routine physical examination or for anemia evaluation in women. At the laboratory, specimens are chosen systematically — stratified by gender, age, and geographic region — from a pool of >5,000,000/yr from a geographic area that includes 85% of the US population. Through a national computer network, a special program selects specimens, relabels them to eliminate identifying data, stores relevent demographic and clinical information, and finally links this information to the HIV test result.

Results. A total of 3 (0.64%) of the first 463 samples tested were seropositive. The first 30,000 samples will be analysed and compared with results from other national population-based or sentinel studies.

Conclusion. Primary care outpatients may be the most representative accessible population for HIV surveillance. Laboratory-based surveillance is a relatively inexpensive method to monitor HIV levels and trends in the general population. Of the first 463 specimens, 0.64% were seropositive.

M.A.0.2

SENTINEL HOSPITAL SURVEILLANCE FOR HIV INFECTION IN THE UNITED STATES: EARLY CROSS-SECTIONAL FINDINGS

St. Louis, Michael E.; Rauch, KJ; White, CR; Anderson, JE; Dondero, TJ; and the Sentinel Hospital Investigation Group. Centers for Disease Control, Atlanta, Georgia, USA.

Objective. To assess the pattern of HIV infection in the metropolitan U.S. in a systematic sample of persons not influenced by self-selection or self-deferral (as are military recruits and blood donors).

Methods. In a nationwide selection of urban hospitals, blood specimens left over after routine testing from patients with conditions thought unlikely to be associated with HIV infection were sampled and anonymously tested for antibody to HIV-1 by enzyme immunoassay and Western blot.

Results. In 1987 and 1988, blood specimens from 45,483 patients in 21 hospitals in 19 metropolitan statistical areas (MSAs) in the U.S. were tested for antibody to HIV. Adjusted to the age, sex, and race distribution of the U.S. population, HIV seroprevalence at these hospitals ranged from 0.2/1000 to 33.7/1000, with a median rate of 5.6/1000. The ratio of seroprevalence in Blacks to Whites at each hospital ranged from 0 to 7.5, with a median rate ratio of 1.7, and in males to females from 1.0 to 18, with a median rate ratio of 2.8. Infection rates in males aged 25-44 years reached 25-30% at two urban hospitals serving communities with high rates of intravenous drug abuse. Among hospitals in MSAs with cumulative incidence of AIDS less than 500/100,000, the cumulative incidence of AIDS in the MSA only explained approximately one fourth of the variation in seroprevalence (R^2=0.24,p<0.05).

Conclusion. The distribution of HIV infection in the metropolitan U.S. is highly heterogeneous and does not strictly follow the pattern of AIDS cases; some urban areas have very high concentrations of HIV-infected persons.

M.A.0.4

EVALUATION OF THE ESTIMATED NUMBER OF HIV INFECTIONS USING A SPREADSHEET MODEL AND EMPIRICAL DATA.

Timothy J Dondero, St Louis M, Andersen J, Petersen L, Pappaioanou M.
AIDS Program, Center for Disease Control, Atlanta, Georgia, USA.

Objective To evaluate existing estimates of total HIV infections in a given general population for consistency with empirical data from a variety of demographic and behaviorial subgroups.

Methods Using as examples three existing estimates of the total US HIV prevalence ranging from 500,000 to 3,000,000, which were derived from mathematical models or direct approaches, we converted these estimates to "expected" percentages (prevalences) of the total population infected. We then further broke these percentages down by age and sex subgroup proportional to the age and sex-specific seroprevalence data from our sentinel hospital populations, arriving at a series of demographic cells each with "expected" prevalence rates. We then compared these "expected" values with corresponding empirical HIV data from childbearing women, ambulatory care patients and other populations, taking into account the likely biases.

Results Overall, US estimates in the vicinity of 1,000,000 total infections or less appeared most compatible with the available empirical data.

Conclusion While no unbiased data exist that directly measure the HIV prevalence in the general population, nor are such data likely soon, several indirect mathematical models and direct approaches have been used to estimate the total number of infections. It is important to evaluate these estimates for consistency with empirical data which were not used in making the estimates. Our evaluation method suggests that US estimates in the vicinity of 1,000,000 are currently most plausible.

M.A.0.6

PREVALENCE AND ESTIMATED INCIDENCE RATES OF HIV INFECTION AMONG CIVILIAN APPLICANTS FOR US MILITARY SERVICE: CURRENT STATUS AND TRENDS

Brundage,John*;Gardner,L*;Burke,D*;McNeil,J*;Visintine,R**;Goldenbaum,M* *et al.*
*Walter Reed Army Institute of Research, Washington, DC, USA,**US Military Entrance Processing Command, North Chicago, Illinois, USA.

Objective. To estimate current status and recent trends of seroprevalence and infection incidence rates among young adults represented by applicants for US military service.

Methods. Since October 1985, approximately 2 million civilian applicants for US military service have been screened for antibody to HIV during routine pre-induction medical examinations. Observed seroprevalences document cumulative infection incidence, overall and in demographically and geographically defined subgroups. Trends in age- and birth-year-specific seroprevalences document infection incidence rates. Univariate and multivariate methods are used for summary parameter estimation.

Results. During the first three years of screening, the overall seroprevalence was 1.4/1000. Seropositivity was significantly associated with age, race/ethnicity, gender, and residence (location and population density). Prevalences among 17 and 18 year olds were comparable, then increased monotonically from age 18 to 31. Generally, prevalences were higher among males, among black nonhispanic (BNH) applicants, and among applicants from urban areas in California, Texas, and along the east coast. During the first three years, the largest absolute increases in birth cohort-specific prevalences were among BNH males; the largest relative increases in birth cohort-specific prevalences were among BNH females.

Conclusion. Military applicant screening data provide unique, up-to-date insights into the distribution, concentration, and rate of spread of the infection epidemic among US young adults. Infection burden and rates of new infection are greatest among BNH young adults. Effects of bias (e.g., self selection) will be discussed.

SIDA/VIH : le sang et les produits sanguins
AIDS/HIV: Blood and Blood Products

M.A.0.7

TRANSFUSION-ASSOCIATED AIDS CASES IN EUROPE

Downs, Angela M.*; Ancelle-Park R.A.*; Brunet J.B.* and national surveillance correspondents of 31 countries
*WHO Collaborating Centre on AIDS, Paris, France.

Objective: To investigate the specific characteristics of European transfusion-associated AIDS cases and to estimate the mean incubation period.
Methods: Details (sex, age at transfusion, dates of transfusion and diagnosis, and disease presentation) of transfusion associated (TA) AIDS cases were obtained through the European AIDS surveillance system. Cases with other recognized risk factors, non-Europeans, Europeans having resided in countries in which heterosexual transmission is predominant, cases multiply-transfused over a period > 1 month and cases incompletely investigated were excluded. Frequency distributions were computed and the mean incubation period is to be estimated by a maximum likelihood method.
Results: Preliminary results relate to 230 cases reported by the end of 1987 in 13 countries (58% of all European cases reported in the surveillance category "transfusion" by the same date). An excess of males (M:F ratio = 1.4:1) is almost entirely accounted for by those aged 50 years and over (56.1% of TA cases); children under 13 years represent 11.3% of cases. OI are present at diagnosis in 89% cases; PML and lymphoma in 4%; LIP and KS in 2%. The number of TA cases diagnosed per year is still increasing, but no cases transfused after 1985 have yet been reported. Mean observed incubation times were 38.1 (range: 7-77) months in adults; 33.5 (11-80) months in children.
Conclusion: Almost all European TA cases present with OI at diagnosis; KS is very uncommon. Maximum likelihood estimates of the true mean incubation period (allowing for truncation of the data) will be based on a larger data set (to end 1988).

M.A.0.8

THE EPIDEMIOLOGY OF TRANSFUSION-ASSOCIATED (TA) AIDS IN THE UNITED STATES

Ward, John*; Reisler, E**; Karon, J**;
*Centers for Disease Control (CDC), Atlanta, Georgia, **Columbia School of Public Health New York, New York, USA.

Objective. Describe temporal and disease characteristics for TA-AIDS cases.
Methods. AIDS case reports to CDC through December 29, 1988 were reviewed. The number of TA-AIDS cases was adjusted for reporting delays.
Results. Through 1988, 2,032 adults with TA-AIDS were reported to CDC (3% of 81,065 adult AIDS cases). Adjusted for reporting delay, the estimated number of TA-AIDS cases increased rapidly thru 1987, but has since remained steady at 270/cases/quarter yr. Of 35 TA-AIDS cases who received blood screened negative for HIV antibody, 33 had other risks for infection. Compared to other cases, TA-AIDS cases tended to be older (58 vs 35 yrs. p=.001), white (74% vs 58% p=.001) and female (37% vs 10% p=.001). The median incubation period was 48 months (range 1-126 mos.) and was shorter for cases age 60 or older than younger adults (43 vs 51 months p=.001). Of the 487 cases diagnosed in 1988, 107 (22%) had wasting syndrome and 46 (9%) had dementia. TA-AIDS cases with dementia were older than those with other diagnoses (64 vs 57 yrs p=.01). When matched by a diagnosis of *P. carinii* pneumonia and controlled for age, more TA-AIDS cases were dead at the time of diagnosis than cases infected by other routes (26% vs 14%, p=.001).
Conclusion. Although cases recently infected with HIV are few, TA-AIDS will continue to be diagnosed. HIV infection should be considered for transfusion recipients with unexplained weight loss or dementia. A low index of suspicion for AIDS in transfusion recipients may delay recognition of HIV related opportunistic illnesses.

M.A.0.9

BLOOD AND PLASMA DONATIONS AMONG A COHORT OF IV DRUG USERS

Nelson, Kenrad E., Vlahov D., Margolick J., Bernal, M.
The ALIVE Study, Johns Hopkins University, Baltimore, MD.

Objective. To describe the recent history of blood and plasma donation among a cohort of active IV drug users (IVDU's) enrolled in an HIV natural history study.
Methods. A cohort of active IVDU's was recruited for a prospective natural history study of HIV infection from street outreach, clinics and hospitals and drug treatment programs. Individuals with AIDS were excluded. Reported history of blood and plasma donation by year was correlated with history of IV drug use, HIV serological status, medical symptoms, stigmata of IV drug use and CD4 levels at baseline.
Results. Overall 398 (24.7%) of 1613 participants were HIV seropositive at baseline; 459 individuals had donated blood or plasma in the past 10 years. Of 245 IVDU's donating between 1985 and 1988, 215 (87.8%) donated at a commercial plasma center, 80.4% had stigmata of drug use, 23 (9.4%) were HIV seropositive at entry into study, and 8 (40%) of 20 seropositive blood donors had CD4 levels below 500. 5 (4.0%) of 126 IVDU's donating in 1987-88 were HIV seropositive.
Conclusion. Our data indicate that blood and plasma donations among active IVDU's is common. Although IVDU's who are HIV seropositive have lower rates of recent donations, increased efforts to exclude IVDU's from the donor pool by education and discontinuation of paying plasma donors seem warranted.

M.A.0.10

PROSPECTIVE EVALUATION OF CONTEMPORARY SCREENED BLOOD DONORS FOR OCCULT HIV INFECTION

Busch,Michael*,**;Eble,B.*;Ulrich,P.*;ElAmad,Z.**; Perkins,H.*,** and Vyas,G.*.
*University of California and **Irwin Memorial Blood Centers, San Francisco, California, USA.

Objective. To monitor the persistent risk of HIV infection from transfusions of screened donor blood.
Methods. Peripheral blood mononuclear cells (PMC) were routinely prepared from a random sample (ca. 50%) of fully screened blood donations. Individual donor's cells were combined into replicate pools containing 1 X 10^6 PMC from each of 50 donors. Pools were cultured for HIV under conditions shown to recover virus from 80% of known infected donors at similar cell inputs and dilutions.
Results. As of December, 1988, 47,963 screened donor specimens were processed, of which pooled PMC from 26,850 have completed co-culture analysis. A single pool, probably representing a single donor, was reproducibly culture positive; HIV detection was confirmed by polymerase chain reaction analysis of pre- and post-culture cells from this pool.
Conclusion. Occasional infected donors are missed by current historical and serologic screening. This ongoing study will eventually analyze 200,000 screened donations, allowing for an accurate estimate of the persistent risk of transfusion-transmitted HIV infections. (Supported by NHLBI Contract HB-6-7024).

M.A.0.11

ROUTINE 6-MONTH MONITORING FOR BLOOD TRANSMITTED HIV INFECTION

Giovanetti, Anna; Mozzi F.; Bellobuono, A.; Vianello, L.; Zanella, A.; Sirchia, G.; et al.
Centro Trasf. Immunol. Trapianti, Osp. Policlinico, via F. Sforza, 35, 20122 Milano (Italy)

Objective. To monitor HIV infection transmission in patients transfused with blood from regular donors selected at 3 levels: 1) information on risky behavior for voluntary self-exclusion, 2) physical examination and confidential face-to face interview, 3) HIV1-antibody screening (ELISA). Methods. Pretransfusion: informed consent obtained to follow-up (which includes also monitoring for posttransfusion hepatitis) and blood sample taken by a medical audit team visiting the wards daily; 3 and 6 mo after transfusion: HIV1-antibody screening. Repeated ELISA positive results are confirmed by Western blot (WB) technique. WB positive results in a previously normal patient and in absence of other causes are considered evidence of HV1 infection by blood. Results. In Jan 1986-Jun 1988 991recipients (18% of all transfused in our setting) transfused with 5309 blood units performed the HIV1-antibody test at least 6 mo after transfusion and 351 other patients transfused with 2520 blood units performed the test at 3 mo only.38 of the 6-mo monitored recipients received 41 HIV-negative blood units from 29 donors who 1-12 mo (median 6 mo) later showed isolated anti-p15 or -p24 reactivity (28 cases) and overt seroconversion (1 case). None of the monitored patients became HIV1 positive. Conclusion. In our setting blood-borne HIV infection monitoring could be easily combined with that for hepatitis. Although the number of monitored patients is too small to draw conclusions, the monitoring system seems suitable to identify infectious, antibody negative donors.

M.A.0.12

NO LATE SEROCONVERTERS AMONG HIV-NEGATIVE PATIENTS AT BONN HEMOPHILIAC CENTER.

Kamps, Bernd,S.*; Niese,D*; Brackmann,H.H.**; Euler,P.**; van Loo,B.**, Kamradt,T.***
*Universitätsklinik Bonn, FRG, **Institut für experimentelle Hämatologie, Bonn, FRG, ***Massachusetts Institutes of Technology

Objective. To investigate the possibility of late seroconversion in patients exposed to HIV.
Methods. In 1984, 322 out of 696 patients treated at Bonn Hemophiliac Center were negative for HIV. From that time, only wet heat-treated or chemically treated Factor VIII preparations have been used except by two patients who seroconverted in 1985. Since 1986, the remaining 320 patients have been tested for HIV by both Elisa and Western Blot at intervalls of 3 to 6 months.
Results. No seroconversion occurred.
Conclusion. A great number of HIV-negative hemophiliacs have been exposed to HIV-contaminated Factor VIII preparations until 1984. The lack of any seroconversion after a 5 years' observation period suggest that late seroconversion might not be of great epidemiologic significance.

M.A.0.13

OBSERVATIONS ON THE NATURAL HISTORY OF HIV-2

Richard Marlink*, Thior I.**; Siby T.**; N'Doye**; Kanki P.*; Romieu I.*; et al.
*Harvard School of Public Health, Boston, USA, ** University of Dakar and the National Center for STD, Dakar, Senegal.

Objective: To determine the natural history of HIV-2 infection in a cohort of West African prostitutes by comparing over time the incidence of clinical and laboratory abnormalities between seropositive and seronegative prostitutes.
Methods: Starting in 1985, we enrolled female prostitutes visiting a nationally supported STD clinic. HIV-2 + prostitutes were matched (1:2 matching ratio) with HIV-2 - prostitutes by age (± 2 years), nationality and initial year of entering the clinic. Out of 92 seropositives now matched with 180 seronegatives, we have collected detailed repeat clinical data on 151 prostitutes. Continued clinical follow-up is being gathered.

A subset of 60 seropositive and seronegative prostitutes have been available to date for CBCs and lymphocyte subset determinations.
Results:

	HIV-2 +	HIV-2 -
Mean period of observation	27 months	31 months
Chronic diarrhea (# cases)	0	0
Weight loss > 10%	1	1
Chronic fever	0	0
Gen. lymphadenopathy	0	0

There has been no cases of ARC or AIDS-like illness. Various minor health problems were not unique to either the seropositive or seronegative group. 2 seropositives and 1 seronegative prostitute have had bilateral 1.5cm axillary lymph nodes. Interestingly, one seropositive case, also seropositive for HTLV-1, has a clinical syndrome consistent with TSP.

Controlling for age, nationality, years in the clinic and number of sexual partners/day, we performed a multivariate analysis to evaluate the various hematologic parameters in relation to serostatus. The mean T4 values were lower in the seropositives, but this was not significant after adjusting for the above parameters. A significant elevation was noted in T8 values for the seropositives after the adjustment. No prostitute tested demonstrated absolute T4 values in the abnormal range.
Conclusions: Extensive historical and physical exam data has yet to document a significant difference in disease development between seropositives and seronegatives in this cohort. The continued prospective characterization of this cohort in Dakar represents a unique opportunity to evaluate the potential for disease in HIV-2 infected individuals.

HTLV-I, HIV-1 AND HIV-2 SEROPREVALENCES IN GUADELOUPE, FRENCH WEST INDIES

Agius, Gérard*; Vaillant, V.*; Dindinaud, G.*; Basilliou, M.*; Zagury, J.F.** and Castets M.*,
*CHU La Milétrie, Poitiers, France; **Université Curie, Paris, France.

Objective. To estimate the prevalence of retroviral infections in Pointe à Pitre, Guadeloupe, French West Indies.
Methods. This seroprevalence study was undertaken at the hospital centre in Pointe à Pitre during November, 1987. Two hundred forty seven sera from patients presenting for routine outpatient care were tested. None of these patients was diagnosed as having AIDS or adult T-cell leukemia/lymphoma. Sera were screened by ELISA for antibodies to HTLV-I (DuPont), HIV-1 (Abbott) and HIV-2 (Pasteur). All sera reactive in either test were confirmed by Western blot (WB) testing. Sera from patients with any WB reactivity were subjected to HIV-1 antigen detection by ELISA (Pasteur).
Results. We found 7 (2.8%) and 1 (0.4%) were positive to HTLV-I and HIV-1, respectively. One subject was doubly infected with HTLV-I and HIV-1. No HIV-2 seropositivity was found. However, 2 sera showed indeterminate HIV-2 WB patterns, one of which was also indeterminate for HIV-1 WB (p24 band alone). The other was seropositive for both HTLV-I and HIV-1. These HIV-2 WB patterns lacking envelope protein reactivities had core protein bands (p26, p56). Only one HTLV-I WB showed an indeterminate interpretation with a core protein band (p19) alone. All HIV-1 antigen detections were negative.
Conclusion. It would be important for public health authorities to evaluate regularly with large seroepidemiologic surveys the dissemination of retroviral infections in these French overseas territories.

M.A.0.15

EPIDEMIOLOGY OF HIV-2 IN FEMALE PROSTITUTES IN SENEGAL

Kanki, Phyllis*; M'Boup, S**, Romieu, I.*, Marlink, R.*, Siby, T**, Essex, M*, et. al. *Harvard School of Public Health, Boston, MA, USA, **University of Dakar, Dakar, Senegal.

Objective. HIV-2 is the predominant human retrovirus in many parts of West Africa. Although HIV-2 shares many genetic and antigenic properties with HIV-1 it also appears to exhibit important biological differences. We have followed a large group of registered female prostitutes (n>1300) in Dakar, Senegal to better understand the epidemiology of HIV-2.
Methods. Since 1985, all women registered at the Institute Hygiene Sociale in Dakar, Senegal were enrolled in the study. Physical examinations, questionnaires regarding risk and sexual behavior were administered and serum samples obtained for STD and retrovirus examination semi-annually. Counseling and condom distribution began in late 1988 and data regarding efficacy of intervention was obtained subsequently.
Results. As of early 1989 ,the overall seroprevalence in 1301 female prostitutes was 9.9% HIV-2, 1.2% HIV-1 and 0.8% HIV-1/2. The majority of women were native Senegalese (73%), with 21% from Ghana and 6% other nationalities. The mean age was 34 yrs, range 21-68, and the mean years of prostitution 6.7 yrs, range 1-19. HIV-2 positive prostitutes were more likely to be older (OR=2.58) and to be non-Senegalese (OR=1.79). The number of years of prostitution was not significantly related to serostatus. Inclusion of all variables in a multivariate logistic model did not modify these results. The spread of HIV-2 in this population was slow as judged by less than 2% seroconversion with 974 person-years of observation. History of transfusion, hospitalization, circumcision,tattooing and scarification were not found to be significant risk factors for HIV-2 infection. 120 person-years of follow-up on HIV-2 positive women has failed find evidence of the development of AIDS or related signs.
Conclusion. The epidemiology of HIV-2 in a high risk population followed over time appears to differ significantly from that of HIV-1. These differences include the risk factors for infection, rates of transmission and clinical outcome.

M.A.0.16

SEROPREVALENCE DU VIRUS HTLV-1 DANS LA POPULATION GENERALE DE SIX PAYS D'AFRIQUE CENTRALE

Delaporte, Eric*; Peeters, M.*; Durand, J.P.**; Porte, P.***; Audoin, J.***; Josse, R.****.
* Centre International de Recherches Médicales, BP 769, Franceville, Gabon;
** Centre Pasteur, Cameroun
*** Hôpitaux Elf Pointe Noire, Congo, Elf Luanda, Angola, **** OCEAC Yaoundé, Cameroun.

Objectifs. Evaluer l'endémie HTLV-1 au Tchad, au Cameroun, en Guinée Equatoriale, au Gabon, au Congo et en Angola.
Methodes. 15 enquêtes ont été réalisées parmi la population générale adulte selon la méthodologie du sondage en grappes. La recherche d'anti-HTLV-1 a été réalisée dans le serum par ELISA (Dupont de Nemours), un serum positif était ensuite retesté par western blot (Dupont). (critères de positivité anticorps anti-noyaux et anti-enveloppe).
Resultats. Près de 6000 personnes vivant en zones rurales ou urbaines, ont pu être ainsi sélectionnées. Les taux bruts de séroprévalence varient de 0.5% au Tchad et au Nord du Cameroun à près de 12% parmi les populations vivant dans la forêt équatoriale (Sud Cameroun, Gabon et Guinée Equatoriale). Les taux de séroprévalence augmentent avec l'âge uniquement dans les zones de forêt. Aucune différence entre les taux masculins et féminins ajustés par l'âge n'a été observée.
Conclusion. Cette vaste enquête sero-épidémiologique sur 6 pays a permis de préciser la répartition du virus HTLV-1 en Afrique Centrale et de définir une zone de forte séroprévalence parmi les populations vivant en pleine forêt équatoriale. Les différents cofacteurs pouvant expliquer cette répartition ainsi que les répercussions pathologiques d'une telle endémie seront discutés.

M.A.0.17

HIV1 and HTLV1 ANTIBODY PREVALENCE IN A US POPULATION SURVEY NHANES-II

Saxinger, Carl*; McQuillan, G**, Haddon, W**, Murphy, R**, Bodner A*** and Gallo, R*

OBJECTIVE To provide a measure of the prevalence of human retroviruses HTLV1 and HIV1 in a representative sampling of the U.S. Population
METHODS Samples were collected 1976-1980 by the NCHS using population-based methodology for a National Health Survey, NHANES-II 9,499 samples were screened by ELISA using HIV-H9 or HTLV1-HUT102 Test results greater than the mean + 3sd were confirmed by western blot Samples were scored positive if reactive by immunoblot with p24 and envelope HTLV1 positive samples were also tested for HTLV2 titer Analyses of correlation between HTLV/HIV seropositivity and variables of age, race, sex, location, population size, income, and education were performed
RESULTS One HIV1 positive serum from an individual with HIV risk factors was identified No further analysis was performed Twenty individuals were seropositive for HTLV1 None appeared to be HTLV2 specific HTLV1 seropositivity was statistically higher in blacks [0.71% (0.23-1.20, 95% C.I.)] and other minorities [1.03% (0-2.45)] than in whites [0.12% (0.05-0.20)] HTLV1 seropositivity was statistically higher for people above the age of 45 yrs for white [0.27% (0.09-0.46, 95% C.I.)] and black [1.89% (0.49-3.4)] persons
CONCLUSIONS Significant numbers of HTLV1 sero-reactive persons exist in regions throughout the U.S. HTLV1 has existed in the U.S. longer than HIV1 The underlying determinants of positivity in the random population, age and race, were similar to IVDA in the U.S. and other HTLV1 endemic populations Mode of transmission of HTLV1, thought to be similar to HIV1 in AIDS risk groups, is unknown in the normal U.S. population

M.A.0.18

HUMAN IMMUNODEFICIENCY (HIV) AND HUMAN T-LYMPHOTROPIC (HTLV-I/II) VIRUSES IN CHILDBEARING WOMEN: TESTS OF 24,569 CONSECUTIVE NEWBORNS.

Stevens, Roy; Wethers, J., Berns, D., and Pass, K. New York State Health Department, Albany, U.S.A.

Objective. To describe the prevalence of HIV and HTLV-I/II infection in childbearing women in New York State.
Methods. Duplicate serum samples were eluted from dried blood spots obtained from anonymous infants at birth. Samples were examined simultaneously by EIA for HIV and HTLV-I/II antibody. Reactive sera were tested by micro western blot with lysate antigens. A commercial (Cytotech) antigen from cell line CH10J2 was used for HTLV-I blots. Specimens with HIV blot bands at 24 and 41 and/or 120/160 Kd or HTLV-I/II bands at 24 and 46 and/or 61/68 Kd were recorded as positive. Test results and data on maternal age, race/ethnicity and birth location were analyzed on a main frame computer.
Results. HIV antibody was detected in 143 (0.58%) newborns; HTLV-I/II in 59 (0.24%). Both antibodies were found in only 5 (0.02%). Positivity was highest in NY City at 1.1 (HIV) and 0.46 (HTLV-I/II), in contrast to 0.07 and 0 in upstate rural communities. Prevalence of antibodies to each virus also differed according to maternal race/ethnicity.
Conclusions. About 6 of every 1000 women giving birth in NY State are infected with HIV, 3 are infected with HTLV-I/II and 0.2 with both. The geographic and racial/ethnic distribution of the viruses describe differences in prevalence and transmissibility.

L'évolution de la politique en matière de santé publique : Où nous sommes-nous mépris? Où allons-nous?
Analysis of Public Health Policy for the Prevention of AIDS: Where Have We Gone Wrong? Where Do We Go from Here?

M.A.O.19 ANALYSIS OF PUBLIC HEALTH POLICY FOR THE PREVENTION OF AIDS: WHERE HAVE WE GONE WRONG? WHERE DO WE GO FROM HERE?

Chairpersons: Donald P. Francis (Berkeley, USA), Bertino Somaini (Bern, Switzerland)

Panelists: Ronald Bayer (New York, USA), Randy Shilts (San Francisco, USA), John K. Watters (San Francisco, USA)

The AIDS pandemic has presented us with a major challenge. Often this challenge has been met with a less-than-adequate response. Yet, in the midst of many failures, there have been many remarkable successes where, in the face of emotion-filled opposition, strong leaders have emerged and acted with courage and clarity. In this session we will address both successes and failures. The speakers are people at various levels inside and outside of government who have personally viewed the alternatives, taken risks and instituted changes. They, through courage, have advanced the cause of HIV prevention and care. They will analyze specific issues that they have encountered, review the problems faced, from where they came and how they were overcome. The ultimate purpose will be to enable us all to better approach the problems of the future through review of past successes and failures.

Tests de dépistage du VIH dans les cliniques de MTS
HIV Testing in STD Clinics

M.A.0.20 SEROPREVALENCE OF HIV AMONG CLIENTS ATTENDING SEXUALLY TRANSMITTED DISEASES (STD) CLINICS IN THE U.S.

McCray,Eugene*; Onorato,I.M.*; Sweeney,P.A.*, and State and Local Health Departments, *Centers for Disease Control, Atlanta, GA, USA.

Objective. To determine HIV seroprevalence in clients attending STD clinics, a sexually active population at increased risk of infection.
Methods. In 1988 and 1989, blinded surveys were conducted in STD clinics in 30 standard metropolitan statistical areas (SMSAs). Blood collected from consecutive STD clients was tested for antibodies to HIV after performing routine serologic tests and removing personal identifiers. Information on sex, age group, race, ethnicity and risk exposure groups for HIV infection is being collected on approximately 100,000 clients.
Results. Preliminary results from 9,494 STD clients in 6 SMSAs from 4 regions showed SMSA specific HIV seroprevalence rates that ranged from 1% to 14% (median, 6%). Rates of 9% were seen in males compared to 3% in females and 13% in Hispanics compared to 6% in whites and 5% in blacks. Rates increased with age to 44 years. HIV seroprevalence among clients whose risk behaviors were unknown or not stated was 4.0% compared to 30.7% in clients with known risk factors.
Conclusions. These results show that STD clinics see large numbers of clients infected with HIV. Seropositivity in STD clients whose risk behaviors are unknown or which cannot be adequately assessed makes interpretation of results difficult and may represent a limitation of blinded surveys. However, blinded surveys are needed to target prevention activities and follow trends in HIV infection. Complimentary nonblinded surveys are needed to obtain detailed information on risk behaviors.

M.A.0.21 SURVEILLANCE OF HIV INFECTION USING A NETWORK OF SENTINEL PHYSICIANS: A PILOT PROJECT IN THE PROVINCE OF QUEBEC.

Alary, Michel*; Castel J.*. *Département de Santé Communautaire, Hôpital du St-Sacrement, Québec, Québec, Canada.

Objective. To evaluate the utility of a network of sentinel physicians for the surveillance of HIV infection in the Province of Quebec.
Methods. From May to December, 1988, physicians working in four different centres (3 in Montreal and 1 in Quebec city) provided anonymous data on each patient submitted to HIV serotesting (Total N=1386). The following variables were collected: test results, country of birth, residence, age, sex, indication for testing, sexual orientation, number of sexual partners, past history of STD and of HIV testing.
Results. The following table presents the distribution of identified risk factors in HIV+ (96/1386=6.9%) and HIV- (1290/1386=93.1%) patients:*

	Seropositive	Seronegative	POR**
Sex-Male	96.8%	69.1%	13.5
Homo or bisexual	93.6%	42.1%	20.1
Presence of symptoms	19.1%	1.7%	13.7
Previous STD	56.3%	39.1%	2.0
Previous HIV testing	37.9%	23.3%	2.0
>=10 sexual partners	27.2%	10.9%	3.1

*Median age=30 years in both groups; **Prevalence odds ratio (p<0.01).
Conclusion. This surveillance network appears to identify the main factors associated with HIV seropositivity. Its future development to cover all the Province of Quebec should allow to moniter adequately HIV infection and eventual changes in risk factors in order to adjust preventive programs.

M.A.0.22 HIV INFECTED STD CLIENTS WHO DECLINE HIV COUNSELING AND TESTING.

Fleming, David*; Bennett,D.*; Klockner,R.*, Gould, J.* Cassidy, D.**, Foster,L.*. *Oregon Health Division, Portland,Oregon, U.S.A.; **Multnomah County Health Division, Portland, Oregon, U.S.A.

Objective. To determine the characteristics of HIV infected (HIV+) sexually transmitted disease (STD) clients who decline HIV counseling and testing (HIV-CT).
Methods. From 6/88 through 9/88, all STD clients at Portland's major public STD clinic were offered HIV-CT. The HIV antibody status for clients declining this service was determined by testing blood routinely drawn for syphilis serology after personal identifiers had been removed. All test results were linked with risk, demographic, and previous HIV testing information provided by the client.
Results. Of the 1740 clients offered HIV-CT, 641 (37%) accepted. Overall, 3% (55/1740) of clients were HIV+. Of these, 73% (40/55) declined HIV-CT. Seropositivity among heterosexual clients was only 0.6% (10/1581). Gay men comprised 9% (159/1740) of all clients, but 82% (45/56) of HIV+ clients, 80% (33/41) of HIV+ clients declining HIV-CT and 90% (27/30) of HIV+ clients who had been tested previously. HIV+ gay men who had not been tested previously were as likely as uninfected gay men to agree to HIV-CT [47% (7/15) vs. 40% (29/72); p=.9]. However, HIV+ gay men who had been tested previously were 3.7 times less likely than comparable uninfected gay men to agree to HIV-CT [16% (4/25) vs. 59% (19/32); p=.001]. HIV+ gay men who had been tested previously and who assessed their risk of infection as high were 6 times less likely than comparable uninfected gay men to agree to HIV-CT [12% (2/17) vs. 73% (11/15); p=.0001].
Conclusion. HIV-infected STD clients who have been tested previously selectively decline HIV-CT. Current STD HIV prevention efforts that focus on testing may become increasingly ineffective as progressively more STD clients are aware they are HIV+. STD clinics must offer alternate interventions that are specifically designed to help individuals who know they are infected but continue to practice unsafe sex.

M.A.0.23 HIV-1 SEROPREVALENCE IN SEXUALLY TRANSMITTED DISEASE (STD) CLINIC PATIENTS IN CENTRAL NORTH CAROLINA.

Suzanne Landis*, V Schoenbach*, D Weber*, M Mittal*, G Koch*, P Levine**
*U of North Carolina, Chapel Hill, NC; **NCI, Bethesda, MD, U.S.A.

Objective. To assess HIV-1 seroprevalence and HIV-1 risk factors in patients attending three large public STD clinics in North Carolina (NC).
Methods. During 5/25/88 to 10/5/88, 3124 consecutive patients had a syphilis serology blood sample anonymously screened for HIV-1; over 90% completed an anonymous, linked, self-administered questionnaire. HIV-1 seropositivity was defined as repeatedly-positive EIA (Electronucleonics) and RIA positive for p24 and gp120.
Results. Study population characteristics were: 55% men; 79% Black, 18% White; median age 24 years; 5% IV drug users; 6% history of treated syphilis; 3% (men) homosexual, 3% (men) bisexual. Of the first 1440 blood sera (data for all 3124 will be reported), 22 (1.4%, 95% CI: 0.8%-2.0%, overall; men 2.2%, women 0.5%; Blacks 1.7%, Whites 1.3%) were positive for HIV-1. Four cases had lived in NC less than one year. Seropositivity rates were 25% (12 cases, including the 2 seropositive IV drug users) among gay/bisexual men, 9% (3 cases) among apparently heterosexual men reporting previous syphilis treatment, and 0.4% (3 cases) among other men. Sexual transmission risk behaviors among men and women, respectively, were: multiple opposite-sex partners (77%,61%), no condom use (52%,65%), anonymous partners (38%,12%), sex for money (9%,3%), and anal intercourse (12%,7%).
Conclusions. HIV-1 is detectable among STD patients in Central NC. Though underreporting of risk factors cannot be excluded, as many as 40% of these patients' HIV-1 infections may have been heterosexually acquired.

M.A.0.24 CENTRES DE DEPISTAGE ANONYME ET GRATUIT FRANCAIS - BILAN DE DEUX CENTRES PARISIENS - VILLE DE PARIS

Cavelier Annick*, Ancelle-Park R.**, Helal H.*, Loygue J.*, Poinsard H.*, Pretet S.* et coll.
*D.A.S.E.S., Paris, France ; **Centre collaborateur O.M.S.-Europe SIDA, Paris

Objectifs. 1° Qui a consulté ces centres de dépistage volontaire? 2° Pourquoi?
Matériel et méthode. Les 4660 autoquestionnaires anonymes exploitables remplis facultativement par les 5101 premiers consultants (91%) entre avril et octobre 1988.
Résultats et analyse. L'anonymat semble avoir plus intéressé que la gratuité 90% ont une protection sociale, 85% un domicile fixe. Clientèle locale, 92% résident en Ile de France, 53% vivent seuls (comme 50% des parisiens). Clientèle ciblée jeune, âgée pour 47% entre 20 et 29 ans, masculine 68%, et particulièrement exposée au risque : toxicomanes 8% dont 1% homosexuel et toxicomane, 14% homosexuels, 16% bisexuels, 62% hétérosexuels(les) dont 2% bisexuelles. 82% des consultants n'utilisent jamais ou mal le préservatif. Les femmes l'utilisent moins que les hommes (P<0.02) homosexuels, bisexuels ou hétérosexuels, même quand elles vivent seules et ont des partenaires multiples et 64% de toxicomanes ne l'utilisent jamais. Les homosexuels et bisexuels l'utilisent régulièrement pour 1/3 d'entre eux. Ils consultent par souci personnel 80%. 70% venaient pour un primo-dépistage. 253 séropositifs VIH1 au Western Blot ont été dépistés (5,4%) et ont été orientés vers un suivi médical et psycho-social.
Conclusion. Cette politique repose sur la responsabilisation individuelle. Quels que soient les résultats du test, les individus, exposés au risque, sont encouragés à modifier leur conduite et non à répéter le dépistage.

M.A.0.25 HIV SEROPREVALENCE IN SEXUALLY TRANSMITTED DISEASE (STD) CLINIC PATIENTS

Moye, John; Bracci,P.; Kappes,R.; Kunches,L.; Day,J.; Timperi, R. et al. MA Department of Public Health. Boston, MA., U.S.A.

Objective: To define the risk-group characteristics of STD clients volunteering for HIV testing during a period when unlinked testing was underway.
Methods: Unlinked HIV testing began 9/1/88 on syphilis serology sera taken at 3 Boston-area STD clinics. All patients received AIDS information and were offered free and confidential HIV counseling and testing.
Results: During the initial 3 months, 180 volunteered for testing (V); their sera probably were subsumed in the 1166 unlinked tests (U) performed in parallel. As shown, V included a larger proportion of gay/bisexual men and IVDU than present in the unlinked series; seropositivity may be lower in V gay men (6%) vs. U (32%) because V anticipated or already knew their status. Although the U series shows 20/880 "unrecognized" risk seropositives, none of these positives appeared in V.

	Unlinked (U)			Volunteers (V)		
	#Tested	(%)	HIV+	#Tested	(%)	HIV+
"Recognized" risk						
Gay/bisexual	47	4	15 (32%)	17	9	1 (6%)
Heterosexual IVDU	45	4	7 (16%)	21	12	3 (14%)
Other high risk	194	16	6 (3%)	33	18	0
"Unrecognized" risk	880	76	20 (2%)	109	61	0
TOTAL	1166	100	48 (4%)	180	100	4 (2%)

Conclusion: The true HIV seroprevalence in STD patients should be monitored via unlinked surveys, in order to interpret the impact of voluntary testing.

M.A.O.26 INCIDENCE OF SEROCONVERSION AND RISK FACTORS IN A COHORT OF HOMOSEXUAL MEN: RESULTS AT 6 YEARS

Sestak, Phil*; Schechter MT*; Willoughby B*; Craib KJP*; Maynard M*; O'Shaughnessy MV**; Nitz R*; Le TN*; Broughton S*; Fay S*; et al.
*The Vancouver Lymphadenopathy-AIDS Study, St. Paul's Hospital and the University of British Columbia, Vancouver, BC, Canada. ** Federal Centre for AIDS, Ottawa, Ontario, Canada

Objective. To determine the rate of seroconversion in a cohort of homosexual men.
Methods. We identified all subjects in our prospective study who were seronegative in 11/82 and who completed at least 2 visits during the period 11/82 to 10/88. Seroconversion was defined as the occurrence of a positive HIV antibody test in an individual who was previously negative. The time of seroconversion was estimated as the midpoint between the last negative and first positive test result. Survival analysis methods were used to calculate seroconversion rates . Risk factors for seroconversion were obtained from the enrolment questionnaire.
Results. A total of 477 subjects were included in the analysis The median length of observation was 51 months (range=4-72). A total of 118 seroconversions occurred during the observation period. The product limit estimate of the cumulative seroconversion rate was 28.5% (±2.3) at 72 months. The annual infection rates for the 6 years were 4.2%, 10.7%, 8.2%, 4.2%, 3.0% and 3.8% respectively. Cox regression revealed the following to independently increase seroconversion risk: history of gonorrhea, use of amphetamines, receptive anal intercourse, receptive fisting, elevated number of male sexual partners in the year prior to enrolment, and age < 30 years in 11/82.
Conclusion. This analysis confirms classical HIV risk factors. It is disconcerting to note that annual seroconversion rates have stabilized at 3-4% over the last 3 years. Although we have previously documented marked overall behaviour change, new infections continue to occur. The rise in annual infection rate in 1988, although not statistically significant, occurred within a closed cohort and at least raises the possibility that some complacency may be setting in. This should be followed carefully in this and other cohorts as there are implications for those trying to promote risk reduction which is not only effective but sustained.

M.A.O.27 INCIDENCE AND PREVALENCE OF HIV INFECTION AMONG HOMOSEXUAL AND BISEXUAL MEN, 1978-1988

Hessol,Nancy A.*;O'Malley,P.*;Lifson,A.*;Cannon,L.*;
Kohn,R.*;Barnhart,L.*;Harrison,J.**;Bolan,G.*;Doll,L.**;Rutherford,G.*.
*Dept. of Public Health,San Francisco,CA, **AIDS Program,CDC,Atlanta,GA,USA

Objective. To describe the incidence and prevalence of HIV infection in a cohort of homosexual and bisexual men who had multiple serum samples and interview data available, and to examine the generalizability of these data.
Methods. We studied 313 men who participated in hepatitis B vaccine trials in San Francisco (SF) since 1978 to determine the cumulative prevalence and annual incidence among susceptibles of HIV infection using lifetable techniques. We also analyzed retrospective data on number of sexual partners and specific high risk behaviors. We used citywide incidence data on rectal gonorrhea to examine the generalizability of the cohort data to all gay SF men.
Results. Cumulative Prevalence and Annual Incidence of HIV Infection

Year:	1978	1979	1980	1981	1982	1983	1984	1985	1986	1987	1988
Cum. Prev.:	0.7%	3.8%	13.7%	28.2%	42.3%	46.7%	48.5%	48.9%	49.7%	49.7%	50.6%
Incidence:	0.6%	3.2%	10.3%	16.8%	19.6%	7.5%	3.4%	0.8%	1.6%	0%	1.8%

Estimated No. of Partners with whom Engaged in Receptive Anal Intercourse

Year:	1978	1979	1980	1981	1982	1983	1984	1985	1986	1987	1988
Mean No.:	14	18	20	16	10	5	1	1	0.4	0.1	<0.1

San Francisco Gonococcal Proctitis Cases by Year

Year:	1978	1979	1980	1981	1982	1983	1984	1985	1986	1987	1988
Number:	4975	4874	5098	4833	4008	2109	1299	708	379	197	169

Conclusion. The decrease in HIV seroconversion in this cohort is paralleled by a decrease in high risk sexual behaviors and a city-wide decrease in gonococcal proctitis.

M.A.O.28 HIV SEROPOSITIVITY IN A CLINIC FOR THE HOMELESS

Greer, Jr., Pedro*; Dickinson, G.**; Parra, F.***; Egea, F.***; Jordahl, L.***; Holmes, R.**.
*University of Miami, Miami, Fl, USA, **Miami VA Medical Center, Miami, Fl, USA, ***State of Fla. Dept. of Health & Rehab. Svc., Miami, FL, USA.

Objective. To correlate prevalence of HIV seropositivity with high risk behavior among homeless persons in Miami.
Methods: The Camillus House Concern, a clinic for the homeless in Miami, offers anonymous testing for HIV antibody. Between 7/1/88-1/20/88, 144 persons requested testing. Tests were performed by EIA with confirmation of positives by Western Blot or immunofluorescence. All persons were interviewed by one of three trained counselors.
Results: Strict criteria for homelessness ("the street" or "a shelter" given for an address) were met by 126 persons. There were 122 men and 4 women, age 19-69, mean 33.8 years old. The rates of seropositivity were as follows: 3/24 (12.5%) homosexuals, 3/21 (14.3%) IVDA, 1/10 with both risk behaviors and 7/71 (9.8%) denying any risk behavior. The overall rate of seropositivity was 14/126 (11.1%). Seventy persons admitted contact with prostitutes, and 4/32 (12.7%) admitting such contact without other risk behavior were seropositive. There was no significant difference for rates of positivity among these groups (P>0.05 by Chi-Square).
Conclusion: These data suggest that the rate of HIV infection among homeless persons voluntarily seeking testing is relatively high, regardless of the type of risk behavior admitted. Random screening programs are needed to accurately define the prevalence of HIV infection in this population, and to provide a basis for preventative and health care programs.

M.A.O.29 PREVALENCE DE L'INFECTION HIV ET DE LA TUBERCULOSE PULMONAIRE DANS UNE POPULATION ASYMPTOMATIQUE EN HAITI.

Lassègue,Alix*;Elie,R.**;Hippolithe,R*;Cesar,D**;Cesar,M.**
*Centre Medical de Port-au-Prince,P-au-P,Haiti.
**Laboratoire d'Investigations Biologiques,P-au-P,Haiti.

Objectif.Déterminer la prévalence de l'infection HIV et de la Tuberculose pulmonaire (TB) dans une population tout-venant d'Haitiens désirant émigrer
Methodes.De Janv.88 à Dec.88,3688 Haitiens (2189 hommes-60%,1499 femmes -40%),d'âge moyen 30±14 ans,de statut économique plutôt moyen,ont été étudiés. 74% provenaient des diverses régions d'Haiti (Groupe A),24% avaient deja vecu à l'étranger dans les 5 années auparavant (Groupe B).Un examen clinique complet,des tests de laboratoire incluant une sérologie anti-HIV par double Elisa et Western Blot,une radiographie pulmonaire,ont été pratiqués sur chacun des sujets.
Résultats.Une sérologie anti-HIV positive a été retrouvée dans 180 cas (4.88%).L'âge moyen des séropositifs (séro+) 32±17 ans avec un sex-ratio de 114 hommes pour 66 femmes.La prévalence de l'infection HIV n'est pas statistiquement différente dans le Groupe A (4.72%) et le Groupe B(5.35%). La prévalence de la TB qui est globalement de 2.14%,est comparable chez les séro- (2.19%) et les séro+ (1.11%).Aucune TB active n'est diagnostiquée chez les seropositifs.
Conclusion.La séroprévalence anti-HIV est globalement de 4.88%,elle n'est pas différente chez les résidents comparée aux émigrés.La prévalence de la TB qui est de 2.14%,n'est pas statistiquement différente chez les séro- et chez les séro+ asymptomatiques,alors que la TB est classiquement associée à plus de 50% des cas de SIDA avérés.

M.A.O.30 EPIDEMIOLOGY OF KAPOSI'S SARCOMA IN AIDS PATIENTS: UNITED STATES.

Beral, V; Peterman, Thomas A; Berkelman, RL; Holmberg, SD; Jaffe, HW. Centers for Disease Control, Atlanta, GA, USA.

Objective: To characterise patients with AIDS-associated Kaposi's sarcoma (KS) and evaluate whether KS may be due to an infectious agent.
Methods: We reviewed cases of AIDS reported to CDC by 3 December 1988.
Results: The percentage of patients with AIDS who had KS varied by AIDS risk group: homosexual men 22%; heterosexual male IV drug users 2.8%; female IV drug users 2.3%; and men with hemophilia 1%. Among homosexual men the percentage of AIDS patients with KS was twice as high for whites and Hispanics as for blacks and higher for 25 to 44-year-old men than for younger or older men. However, there were no sizable race or age differences in the percentage with KS among non-homosexuals. Over time, the percentage of patients reported with AIDS-associated KS declined at a similar rate in all risk groups; the percentage with KS in 1988 is approximately one fourth of that in 1982. After adjusting for risk group, age, race, and year of diagnosis, KS was more frequently reported for patients from California or New York than from other states.
Conclusion: If KS is caused by an infectious agent it is more likely to be transmitted by homosexual contact than by blood. The reasons for the age/race/geographic differences in percentage of patients with KS should be explored in other studies. The decline in KS over time may be due to increasing recognition of other diseases associated with AIDS, decreasing exposure to the putative KS agent in patients now developing AIDS, and/or different incubation periods for KS and other manifestations of AIDS.

M.A.O.31 EPIDEMIOLOGY OF HIV ENCEPHALOPATHY IN THE UNITED STATES

Janssen, Robert; Stehr-Green, J.; Starcher, T.
Centers for Disease Control, Atlanta, GA, USA

Objective:To determine the frequency of HIV encephalopathy (HIVE) in patients reported with AIDS and to evaluate possible associations with demographic factors. Methods:A case of HIVE was defined as a person who was HIV seropositive with disabling cognitive and/or motor dysfunction in the absence of a condition other than HIV infection that could explain the findings. Cases were reported to CDC from September 1, 1987, when encephalopathy was added to the AIDS case definition, through December 31, 1988. Results: Over the 16-month period, 1153 (3.0%) of 38666 adults and 22 (3.3%) of 666 children (< 13 years old) with AIDS were reported to have HIVE as their only early manifestation of AIDS. Overall, 6.5% of adults and 11.5% of children had HIVE. Reported AIDS cases with HIVE only, occurred in a bimodal distribution with peaks in children < 5 and adults > 70. In general, in adults, rates of HIVE increased with age (p < .0001 for trend), even among persons < 50 years old (p=.02).

Age	#HIVE/Total(%)	Age	#HIVE/Total(%)	Age	#HIVE/Total(%)
0-4	20/528 (3.8)	20-29	181/8107 (2.2)	50-59	125/2744 (4.6)
5-12	2/138 (1.4)	30-39	517/18147 (2.8)	60-69	56/930 (6.0)
13-19	5/151 (3.3)	40-49	244/8270 (3.0)	70+	25/317 (7.9)

Although there were no associations of HIVE among reported adult cases with respect to sex, racial/ethnic group, geographic location, or HIV risk group, the frequency of HIVE in children < 5 years old was significantly higher in those with a history of blood transfusion (6/40,15%) than in children without such a history (14/488,2.9%, p=.002). Conclusions: HIVE is uncommon as the only reported early manifestation of AIDS but appears to be most common at the extremes of age.

La transmission sexuelle du VIH (partie 1)
Sexual Transmission of HIV (Part 1)

M.A.0.32 SERUM ANTIBODY TO HAEMOPHILUS DUCREYI AS A RISK FACTOR FOR HIV INFECTION IN AFRICA, BUT NOT IN EUROPE

Piot, Peter*, Van Dyck, E.*, Ryder, R.W.**, Nzila, N.**, Laga, M.* et al.
* Institute of Tropical Medicine, Antwerp, Belgium; ** Projet SIDA, Kinshasa, Zaire

Objective: To determine whether serum IgG (Ab) antibody to Haemophilus ducreyi, the causative agent of chancroid, is associated with HIV infection in populations where genital ulceration (GUD) is endemic.
Methods: H. ducreyi IgG Ab was determined in an ELISA using a sonicated H. ducreyi antigen on sera preabsorbed with a pooled sonicate of 3 other Haemophilus sp. Sera were from heterosexual and homosexual men in Belgium, 1988 (n = 254), female prostitutes in Kinshasa, Zaire, 1988 (n = 697), adult men and women from the rural Equateur province, Zaire, 1986 (n = 100), and men with an STD in Rwanda, 1986-1987 (n = 303). Mean ages: 28-31 yr.
Results: H. ducreyi seroprevalence rates were 37 % - 44 % in the African populations. In the 2 African populations with high HIV prevalence, H. ducreyi Ab was strongly associated with HIV antibody (odd ratios: 3.0-3.3). This was not observed in Belgians at risk for HIV. In the rural Equateur population

Origin	Population	Prevalence of HIV in sample	H. ducreyi antibody (%) HIV NEG	HIV POS	p
Belgium	gay men	21 %	3/184 (2)	2/ 50 (4)	NS
Rwanda	men with STD	57 %	61/130 (47)	126/173 (73)	<.001
Kinshasa, Zaire	female prostitutes	40 %	252/444 (57)	205/253 (81)	<.0001
Equateur, Zaire	mixed adults	10 %	32/ 90 (35)	5/ 10 (50)	.17

44 % of prostitutes had H. ducreyi Ab vs 28 % of other adults (p < .01). H. ducreyi Ab was also associated with the presence of GUD, a history of GUD in the African study groups, but not with a positive serology for syphilis.
Conclusions: Serological evidence of past infection with H. ducreyi was a risk factor of HIV infection in African populations, further supporting the amplifying role of GUD in the sexual transmission of HIV. H. ducreyi serology may be a useful tool to rapidly assess the potential for HIV spread in pattern II populations.

M.A.0.33 ASSESSMENT BY PCR OF TRANSMISSION OF HIV FROM INFECTED HEMOPHILIACS TO THEIR SEX PARTNERS AND CHILDREN

Indira Hewlett*; Laurian, Y**; Epstein, J*; Allain, JP***, *Center for Biologics Evaluation and Research, Bethesda MD; **IHTC, Bicetre, France; ***Abbott Laboratories, N. Chicago, U.S.A.

Objective. To evaluate transmission of HIV infection from men with hemophilia to their female sex partners and children.
Methods. HIV antibody and antigen were tested with assays available in Europe . Polymerase chain reaction (PCR) using primer pairs and probes specific for gag and env regions of HIV-1 were used to detect HIV DNA in serum samples and corresponding peripheral mononuclear cells in some cases. PCR + was defined as a reaction with both gag and env amplified sequences and specificity assessed with extensive positive and negative clinical controls.
Results. Sex partners of 26 sero positive (sero+) hemophiliacs were either sero+/PCR+ (5), or sero-/PCR+ (9), or sero-/PCR- (12). In addition the partner of one sero-/PCR+ hemophiliac was also sero-/PCR+ while the partner of a sero-/PCR- hemophiliac was negative for both markers. PCR positivity in sero- females was unrelated to date of seroconversion, duration of sex partnership, HIV antigenemia or clinical condition of the hemophiliac. 8 children from 5 couples were studied. 2 were born prior to their father's seroconversion and were sero-/PCR-; 2 born from sero+ mothers were sero-/PCR+; 2 born from sero-/PCR+ mothers were sero-/PCR-; 2 born from sero-/PCR- mothers were negative for both markers.
Conclusion. 54% of sex partners of sero+ hemophiliacs have evidence of exposure to HIV, either as persistent (19%) or silent infection (35%). More sex partners and infants from sero-/PCR+ persons need to be studied to evaluate the transmissibility of HIV genome.

M.A.0.34 A PROSPECTIVE COHORT STUDY OF HIV-1 SEROCONVERSION IN PATIENTS WITH GENITAL ULCER DISEASE IN NEW YORK CITY

Telzak, Edward E.* **; Chiasson, MA*; Stoneburner, RL*; Rivera, J*; Jaffe, HW***; Schultz, S*. *New York City Dept. of Health, NY, NY, **Memorial Sloan-Kettering Cancer Center, NY, NY, ***CDC, Atlanta, GA. U.S.A.

Objective. To compare HIV-1 seroconversion rates in patients who present to a sexually transmitted disease (STD) clinic with genital ulcers (GU), a putative cofactor in HIV-1 transmission, to those who present for diagnosis and/or treatment of a non-ulcerative STD.
Methods. In a New York City STD clinic, where high rates of HIV-1 and genital ulcer disease coexist, HIV-1 seronegative patients with and without GU were followed for 3 months. Questionnaires were administered at the time of entry, at 3 weeks, and at 3 months to obtain data on demographics, sexual behavior and IV drug use. Repeat serum for HIV-1 antibody was obtained at 3 months.
Results. To date, 210 patients have completed the study; 50 with GU and 160 without GU. Of the 50 patients with GU, 39% had chancroid, 22% syphilis, 19.5% herpes, and 19.5% had multiple GUs. HIV-1 seroconversion occurred in 2/50 (4%) of the GU patients and 0/160 of the non-GU patients (p=0.06). Both seroconverters were males who denied a history of IV drug use and sexual contact with men. They both had unprotected vaginal intercourse while their ulcers were present.
Conclusions. Persons with a GU may be at increased risk of contracting HIV-1 through sexual contact. In areas with concurrent epidemics of GU disease and HIV-1, increased efficiency of HIV-1 transmission may result in increased rates of heterosexual transmission.

M.A.0.35 EXTRAMARITAL/PROSTITUTE SEX AND GENITAL ULCER DISEASE(GUD) ARE IMPORTANT HIV RISK FACTORS IN 7068 MALE KINSHASA FACTORY WORKERS AND THEIR 4548 WIVES

Ryder, Robert*/**; Hassig, S.*; Ndilu, M.*; Behets, F.*; Nanlele, K.*; Malele, B.*; Bishagara, U.*; Kashamuka, M.*. *Projet SIDA, Kinshasa, Zaire; **CDC, Atlanta, GA, U.S.A.

Objectives. To determine the prevalence of GUD and quantify its role in HIV transmission in a Kinshasa population at low risk of STD.
Methods. A cohort of 7068 male employees and 416 female employees of either a textile factory or a bank and 4548 wives of employees have been examined.
Results. HIV seroprevalence was 3.6% for employees and 5.8% for wives. Men with no recent history of extramarital sex had an HIV prevalence of 2.8% vs 4.4% for men with 1-5 partners and 8.7% for men with more than 5 (P<0.001). Twenty-eight per cent of HIV(+) male workers reported vaginal-sex with a prostitute in the past 2 years vs 22% of HIV(-) men (P<0.001). Eighteen per cent of HIV(+) men reported GUD in the previous 5 years vs 7.2% of HIV(-) men (P<0.001). During the same time period, 27% of 220 HIV(+) women reported GUD vs. 13% of 4744 HIV(-) women (p=<.001). Stepwise logistic regression demonstrated that the most statistically significant HIV risk factors were: history of GUD since 1982 (p<.0001), history of urethritis in the previous 2 years (men only) (p<.001), young age (women only) (p<.001), and a history of a blood transfusion since 1982 (p<.01). In 4487 married couples studied, a highly significant association between couple concordance for GUD and HIV was demonstrated.
Conclusion. While previous studies in populations at high risk of STD have demonstrated a strong association between GUD and HIV infection, the present study demonstrates the same strong association in male workers, their wives and female workers drawn from a low risk Kinshasa population. The high prevalence of extramarital/prostitute sex and STD in male employees emphasizes the importance of incorporating STD control activities in HIV prevention programs in both high and low risk populations. STD/HIV prevention programs in the private sector will likely decrease employee and dependant HIV-associated morbidity and mortality.

M.A.0.36 EFFICACY OF NONOXYNOL-9 IN PREVENTING HIV TRANSMISSION

Kreiss, Joan*; Ruminjo,I**; Ngugi,E**; Roberts,P*; Ndinya-Achola,J**; Plummer,F*** *U. of Washington, Seattle, USA, **U. of Nairobi, Kenya, ***U. of Manitoba, Winnipeg, Canada

Objective. To assess the efficacy of N-9 in preventing HIV transmission.
Methods. A prospective randomized placebo controlled study was conducted among HIV seronegative prostitutes in Nairobi, Kenya.
Results. Ninety-eight women were enrolled, assigned to the use of N-9 contraceptive sponges (51) or placebo vaginal suppositories (47), and followed for a mean of 10 months (range 1-22). N-9 use was associated with a higher incidence of genital ulcers (17 vs 7% of exams, p<.001) and fungal vulvitis (19 vs 10%, p<.001) and a lower incidence of gonorrhea (21 vs 36%, p<.001). HIV infection occurred in 20 women in the N-9 group and 15 in the placebo group. Excluding women who were lost to follow-up or who seroconverted within 2 months of enrollment, 16 (46%) of 35 N-9 users and 10 (28%) of 36 placebo users developed HIV Abs by ELISA and WB (p=NS). By survival analysis, the cumulative proportion of women who seroconverted was 55% among N-9 users and 45% among placebo users (p=NS). Eleven (69%) of 16 seroconverting women in the N-9 group had antecedent genital ulcers within 2 months of seroconversion compared to only 2 (20%) of 10 in the placebo group (p=.04).
Conclusion. In this study of Nairobi prostitutes, we have failed to demonstrate efficacy of N-9 use in preventing heterosexual transmission of HIV. N-9 use was associated with an increased frequency of genital ulcers and of genital ulcer-associated seroconversion. Spermicide studies in other high risk populations are needed before recommendations regarding spermicide use can be knowledgeably made.

M.A.0.37 ANTI-HIV EFFICACY OF BARRIER CONTRACEPTIVES IN HIV-DISCORDANT COUPLES

S.K. Hira*; Paul Feldblum**; J. Kamenga*; G. Tembo*
*University Teaching Hospital, Lusaka, Zambia
**Family Health International, Research Triangle Park, NC, 27709 USA

Objective To Measure the efficacy of condoms and spermicides in preventing HIV infection among seronegative regular sexual partners of seropositve persons.
Methods In September 1988 we initiated a study of condom and spermicide use among the HIV-discordant couples who regularly visit the U.T.H. STD clinic. After informed consent, the couples are counseled on the use of condoms and spermicidal suppositories, gel and film. Blood is drawn for HIV antibody tests, an admission questionnaire is completed, and the couple is given a pictorial coital log to maintain between visits. At quarterly follow-up visits contraceptive supply, counseling and blood tests are repeated, information on sexual activity is summarized from the logs, and the physical status of both partners is assessed. If a new seroconversion occurs (case), three controls will be selected. A case-control interview questionnaire will collect information on exposures and behaviors relevant to HIV infection.
Results Seventy-one couples have been enrolled, with 47 male-positive and 24 female-positive couples. Each couple has accepted at least one spermicidal product as well as condoms. Three-month follow-up visits have been completed by 13 couples and no sero-conversions have been detected. For 9 of 13 couples each reported coital episode has been protected by a barrier method.
Conclusion Initial barrier acceptability is promising. We will describe findings from the first half-year of the study.

Infection par le VIH chez les détenus
HIV Infection in Prisoners

M.A.0.38 HIV INFECTION SPREAD IN NORTHERN ITALIAN PRISONS.

Serraino Diego, Franceschi S., Vaccher E., Bullian P., Gerdol D., Tirelli U.
Epidemiology Unit* and Medical Oncology**, Aviano Cancer Centre, Aviano (PN) - Italy

Objective. To assess patterns of HIV spread from intravenous drug users (IVDUs) to other inmates in three prisons in the northeastern part of Italy.
Methods. Information were collected among 544 IVDUs as regards past history of drug abuse, imprisonment and behaviours patterns known to be an important way of HIV spread.
Results. 231, 201 men and 30 women, out of the 544 IVDUs (43%) reported to have been imprisoned at least once. Among these 231 IVDUs, 44% of the men and 27% of the women were HIV seropositive. 111 IVDUs (38% of whom seropositive) reported to have been imprisoned in cells with inmates not otherwise at risk for HIV infection and 93 (47% of whom seropositive) shared cells with other IVDUs. Razor and toothbrush sharing was reported by 10% of HIV seropositive and seronegative IVDUs. Needle sharing and homosexual intercourses in prison were admitted only by a small minority of IVDUs, 9% and 2% respectively.
Conclusion. A large proportion of HIV seropositive IVDU prisoners shares cells with other IVDUs as well as with individuals not otherwise at risk. The segregation of prisoners who are seropositive does not seem to be justified. On the contrary, the practicability of issuing sterile injecting equipment to IVDUs prisoners requires much attention, in order

M.A.0.39 RETROVIRUS SEROPREVALENCE IN THE SHORT-TERM INCARCERATED: THE PHILADELPHIA PRISON SEROPREVALENCE STUDY

Davidson, Bruce*; DeMeis A*; Paul DA**; Kline R*** and Quinn TC***.
*Philadelphia Department of Health, Philadelphia, PA, USA, **Abbott Laboratories, North Chicago, IL, USA, ***Johns Hopkins University School of Medicine and National Institutes of Health, Baltimore and Bethesda, MD, USA

Objective: To estimate seroprevalence of HIV-1 and HTLV-1 infection in consecutive new admissions to a city prison, where 25% of new admissions are discharged within 2 days and 40% within 7 days (with over 15,000 prison admissions annually).
Methods: Sera for a serologic test for syphilis is routinely taken from new prison admissions. In 95% of new prisoners this is obtained by venipuncture; approximately 5% undergo fingerstick if veins are inaccessible. In this study, discard blood from venipuncture from 1000 admitted prisoners was tested for HIV-1 antibody and core antigen and for HTLV-1 antibody over a two-month period. Antibody tests were confirmed by immunoprecipitation; positive HIV-1 antigen tests were repeated and then confirmed by blocking with antibody. The prisoner's sex, race, and age were recorded for each result.
Results: HIV-1 infection rate was 4.6% among consecutive prison admissions from whom venipuncture blood could be obtained. The rate of indeterminate tests was 0.3%. Of those testing positive for HIV-1, 6.1% had positive core antigen tests without detectable HIV-1 antibody. Overall, 3% of antigen-positive prisoners (n=6) were antibody-negative. Seroprevalence rates in white, black, and Hispanic men prisoners were equal. The rate of HTLV-1 antibody seroprevalence was 0.8%; the rate of indeterminate immunoprecipitation tests for HTLV-1 was also 0.8%. No subject showed evidence of co-infection with HIV-1 and HTLV-1. All but one of the positive HIV-1 tests and HTLV-1 tests were found in men.
Conclusion: HIV-1 seroprevalence among new Philadelphia prison admissions is equal among races and almost limited to men, in subjects from whom venous blood could be obtained. HTLV-1 infection is also nearly limited to men, at a lower rate. Education and training to modify risk behavior in this population ought to be a high priority, as both the high number of prison admissions and the circumstance of early prison discharge may raise the risk of HIV-1 transmission in the surrounding community.

M.A.0.40 ETUDE DES RISQUES DE CONTAMINATION PAR LES VIRUS DE L'HEPATITE B, DU VIH1 EN MILIEU CARCERAL.

ESPINOZA Pierre*, BALIAN P.*, BOUCHARD I.*, DGS **
* Hopital de Fresnes Allée des Thuyas 94261 FRESNES CEDEX France.
** Direction Générale de la Santé - Bureau de la Toxicomanie.

INTRODUCTION : Effectif de la Maison d'Arrêt 3 800 détenus, flux annuel 12 000. Taux de séropositivité VIH1 12,5%, prévalence des marqueures VHB 55%.
OBJECTIFS : Etudier les risques de contamination par les virus VHB et VIH1 chez des détenus incarcérés plus de 1 an.
METHODES : ①. Enquête sérologique : étude des marqueurs VIH1 (ELAVIA PASTEUR - Confirmation Western Blot) VHB (Radio-immunologie Abbott) à l'arrivée et après un séjour supérieur à 12 mois. ②. Le médecin recherche des pratiques à risque apprécie le respect des règles d'hygiène générale. ③. Questionnaire rempli par le détenu qui le dépose dans une urne fermée à clés. ④. Conditions d'étude : consentement du patient, anonymat des questionnaires, confidentialité.
RESULTATS : ①. 276 hommes, âge moyen 32 ans, homosexualité 2,4%, toxicomanie IV 13%, sniff 13%. Aucune permission de sortie. Echange de vaisselles (90%), de rasoirs 2,6%, tatouage 4%, plaie 19%. ② A l'entrée : séropositifs 6%, VHB 45%, aucun nouveau cas de séropositivité VIH1, VHB sur les prélèvements après une durée moyenne d'incarcération de 16 mois (extrêmes 11-57). ③. 3 affirmaient avoir eu des relations homosexuelles en prison dont 1 homosexuel séropositif (7 partenaires) aucun ne déclare l'usage de drogue IV. ④. 10 ont été témoins de relations homosexuelles, viol 1, usage de drogue IV par d'autres 3 cas (Enquête anonyme).
CONCLUSION : Pas de contamination prouvée sérologiquement malgré l'existence prouvée de pratiques à risquès. Nécessité de développement des mesures de prévention.

M.A.0.41 Tittle: Prevalence and risk factors for HIV infection among adolescent inmates in Madrid.

C.Colomo*,V.Zunzunegui**,P.Estebanez*,J.Sastre*, M.Rua*,F.Babin*. * Madrid City Council, ** EASP, Granada, Spain.

Objective: Identify sociodemographic characteristics and risk practices for HIV infection among adolescents from poor areas of the Madrid. Material and methods: Serostatus for HIV and epidemiologic data through personal interviews were collected from 236 volunteers, aged 16 through 20, at the Juvenile Prison of Madrid between December 1987 and September 1988. Results: Overall prevalence of HIV infection was 59%. Eighty seven per cent of the inmates had a history of IVDU. and the prevalence of HIV infection for these IVDUs was 67%. Only two of the seropositive men had not used drugs intravenously: One of them was a male prostitute, the second one had tattoos and had contacts with prostitutes. Having one or more siblings who were IVDUs, the number of years of adiction, and a history of overdose episodes were significant risk factors for infection ($p<0.05$). Twenty three per cent of the inmates reported having anal intercourse with their heterosexual risk partners and 59% of them had stable heterosexual partners. Very few, 7%, of them had always used condoms and 64% are still sharing syringes. Conclusion: These young men are at high risk of HIV infection and in addition, they are at high risk of infecting other IVDUs and those women who have sexual contact with them, mostly their stable sexual partners, in spite the health education activities that have been carried out. Therefore, it is urgent to reach them through more creative efforts.

M.A.0.42 SEXUAL PRACTICES AND HIV INFECTION IN SOME ZAMBIAN PRISONS

Maboshe, Mwendaweli M*; Simooya O.O.*; Hira, S.K.*; Chimfwembe, E.*; Perine, P.L.**; Sandala, M.L.**; Mukunyandela, M.*
*Tropical Diseases Research Centre, Ndola, Zambia, **University Teaching Hospital, Lusaka, Zambia.

Objectives. To establish the seroprevalence of HIV infection amongst inmates in 5 urban prisons in Zambia as well as to study their sexual habits.
Methods. A questionnaire on clinical, social and sexual history was administered to all inmates who had been in prison for 3 months or more after which blood specimens were taken. The serum samples were screened for HIV antibodies using ELISA (Abbott) and those that tested positive were confirmed using Recombigen (Cambridge BioScience Corp) and Immunofluorescent Assay (IFA). In Lusaka, anal smears were taken from prisoners and controls (STD clinic attendees) and cultured on Thayer-Martin medium for gonococci.
Results. 256 (16.1%) of the 1593 inmates tested positive for HIV and homosexual activity was in 203 (12.2%) of the 1668 respondents. 15 (9.6%) gonococcal cultures were positive in 157 anal smears from prisoners and none was positive from 100 controls. The results are summarised in table below:

Prison	HIV prevalence %	Homosexuality %
Mukobeko Maximum (Kabwe)	9.2	13.8
Mukobeko Medium (Kabwe)	15.2	13.3
Kamfinsa (Kitwe)	14.8	18.2
Lusaka Central	29.0	4.7
Lusaka Remand	19.8	0.0

Conclusion. HIV infection is prevalent among inmates in some Zambian prisons and that homosexuality exists under deprived sexual conditions.

M.A.0.43 CORRECTIONS AIDS PREVENTION PROGRAM (C.A.P.P.) IN NEW YORK CITY

Hayes-Cozier, R., Vowels, J.M., Rautenberg, Ellen, Kayser, L.C., Solis, I., New York City Department of Health, N.Y., U.S.A.

Objective: To provide AIDS prevention services to a high-risk population including current and former IV drug users, male inmates who have sex with men, inmates who have been diagnosed with AIDS or ARC.
Methods: The program consists of the following: 1)Training of corrections staff (officers and civilians); 2)Education of all inmates during initial orientation sessions; 3)Group and individual education sessions; 4)Condom distribution on a pilot basis to inmates; 5)Discharge planning for inmates before release; 6) Development and distribution of materials geared to the needs and concerns of inmates at risk. Counseling and testing services are also available through onsite medical clinics and complement educational efforts.
Results: 1)Over 50,000 inmates have received AIDS education/prevention information with 10 staff. 2)Over 40% of the Department of Corrections staff received AIDS education since the program was initiated in 1987. 3)DOH AIDS educators are in great demand throughout the prison system, as is demonstrated by frequent requests for their services. 4)Corrections counseling staff have received AIDS education and provide back-up for DOH educators in case of illness.
Conclusion: In order for a corrections AIDS prevention program to succeed, the cooperation of the agencies (e.g. Department of Corrections) must begin from the inception of the program. The vital elements of this program must include: 1) education and information for Corrections staff, 2)education and information for inmates, 3)education of family, friends and significant others of inmates, 4) materials relevant for incarcerated populations, 5) appropriate resources and referrals for inmates upon release. In an incarcerated population, the primary focus must be on the reduction of fear, anxiety and the adoption of risk-reducing behaviors once released back into society.

Histoire clinique de l'infection au VIH : Cofacteurs et progression
Natural History of HIV Infection: Co-Factors for Progression

M.A.0.44 INCIDENCE OF AIDS IN HOMOSEXUAL MEN DEVELOPING HIV-1 SPECIFIC ANTIBODY

Phair, John, Muñoz, A., Kingsley, L., Fox, R., Kaslow, R., Visscher, B., and Jacobson, L.,Multicenter AIDS Cohort Study, Chicago, IL., U.S.A.

Objective: To characterize individuals developing AIDS within 4.5 years of developing HIV infection in a study of homosexual men.
Methods: 300 men in the MACS developed Western blot confirmed HIV specific antibody between 2 semiannual visits. The time of seroconversion (SC) was defined as the midpoint between 2 followup visits.
Results: 18 of the 300 progressed to AIDS with 54 months of SC. The incidence rate by 6 month period per 10,000 person months of observation rose from 0 at 6 and 12 months to 74 during the 36-42 month interval. Using the product limit estimator of the distribution of AIDS-free time 89.9% were free of AIDS at 42 months. Men developing AIDS averaged 578.4 ± 388.5 lifetime sexual partners compared to 322.2 ± 328.8 for the AIDS free men. The T-cell phenotype did not differ between participants developing AIDS and those who remained AIDS-free, at the visit before SC. Changes in CD4, CD8 and hemoglobin levels post SC, however, differentiated men who developed AIDS from those who remained AIDS-free.
Conclusion: AIDS did not develop during the 1st 12 months of HIV-1 seropositivity. The subset of HIV-1 infected men (6.0%) who developed AIDS within the first 54 months of infection had a greater number of lifetime sexual partners and more marked changes in T-cell phenotype immediately following and subsequent to SC. At the visit prior to SC, the T. cell phenotype distribution did not differentiate the 2 groups.

M.A.0.46 HUMAN HERPES VIRUS 6 (HHV6) IN A COHORT OF HOMOSEXUAL MEN

Holmberg, Scott*, Lopez, C.A.**, Byers, R.H.*, Rutherford III, G.W.***, and Jaffe, H.W.*
*AIDS Program and **Division of Viral Diseases, CDC, Atlanta, GA; and ***San Francisco Department of Health, San Francisco, CA, USA

Objective. To examine the relationship of HHV6 infection to HIV infection or to the clinical progression to AIDS and other HIV-associated conditions.
Methods. Anti-complement immunofluorescence test for HHV6 in sequential serum specimens from pairs of homosexual men who did/did not develop HIV infection (64 pairs), AIDS (6), ARC (4), lymphadenopathy (6), or lymphopenia (18).
Results. There was no difference in HHV6 seroreactivity in serum from 55 men who acquired HIV infection and 58 men who remained HIV-seronegative. Also, there was no overall difference in HHV6 seroreactivity in serum from 34 HIV-seropositive (HIV+) men who developed HIV-associated diseases and 34 HIV+ men who did not. Independent of HIV-serostatus, of 93 HHV6+ men with two or more samples drawn and tested, the level of HHV6 seroreactivity declined markedly in 47 (51%), and 26 (28%) seroreverted to HHV6-. Compared to HHV6- men, HHV6+ men had similar numbers of sex partners and sexual practices. Despite similar duration of HIV infection, HIV+/HHV6+ men were significantly less likely than HHV+/HHV6- men to develop AIDS (13/26 vs. 77/105; stepwise logistic analysis, p= 0.013)
Conclusion. HHV6 did not induce long-term antibody response by the assay we used, was not apparently sexually transmitted, and was not a risk factor for HIV infection. Men who were HHV6+ were actually less likely to develop AIDS than were HHV6- men: we are examining this issue by polymerase chain reaction (pcr) for HHV6 in DNA of HIV+ men who have/have not developed AIDS.

M.A.0.48 PSYCHOSOCIAL CO-FACTORS IN ILLNESS ONSET AMONG HIV POSITIVE MEN

Kessler, Ronald;*Joseph, J.;*Ostrow, D.;*Phair, J.; **Chmiel,J.,;**Rusk, C.**University of Michigan, Ann Arbor, Michigan,U.S.A.**Northwestern University, Chicago, Illinois, U.S.A.

Objective. To evaluate the effects of stressful life experience and mood on illness onset in a sample of initially asymptomatic HIV positive men.
Methods. A psychosocial questionnaire has been administered to participants in the Chicago site of the Multisite AIDS Cohort Study (MACS) biannually since 1985. Concurrent biomedical evaluation has made it possible to study the relationship between psychosocial variables and illness onset in a prospective design. The subsample of initially asymptomatic seropositive men was studied. Discrete-time survival analysis with time-varying exogenous variables was used to estimate the impact of distressed mood and major stressor events on illness onset measured by physical exam. Control variables were introduced for baseline immunologic functioning.
Results. Distressed mood and the occurrence of stressful life events are both associated with elevated risk of illness onset. Risk of illness onset over a six month prospective time period is more than three times greater with exposure to major stressor events.
Conclusion. This investigation documents that stressor events and distressed mood are implicated in illness onset among previously asymptomatic seropositive men. It is not clear from this analysis whether the pathways involve behavioral changes which might potentiate the virus or whether more direct psychoimmune associations are involved. However, the results imply clear intervention implications that seropositive men may prolong the time they are asymptomatic by minimizing exposure to stress-provoking life events.

M.A.0.45 IMMUNOLOGIC MARKERS MODEL THE RISK OF AIDS

Alexander Krämer*, PS Rosenberg*, D Fuchs**, RJ Biggar*, WA Blattner*, JJ Goedert* *National Cancer Institute, MD 20892, USA, **University Innsbruck, Austria

Objective. To define predictors of AIDS in HIV-seropositives.
Methods. Serum neopterin, beta2-microglobulin (B2), T4 count and T4/T8 ratio were evaluated in a cohort of HIV-infected homosexual men followed from estimated dates of seroconversion. Time-dependent covariate analysis was used to determine at what year before AIDS onset each marker was predictive.
Results. During 1982-88, 48 of 132 subjects (36%) developed AIDS. T4/T8 ratio was predictive ≥4 years before AIDS (p=.03; Table: O=observed, E=expected AIDS cases by T4/T8 at intervals before diagnosis).

Marker	2-12			12-24			24-36			36-48			48-60months		
T4/T8	O	E	O/E	O	E	O/E	O	E	O/E	O	E	O/E	O	E	O/E
2.6-0.7	1	8	0.1	8	13	0.6	9	14	0.6	5	8	0.6	3	6	0.5
0.6-0.5	3	8	0.4	8	13	0.6	8	11	0.7	5	7	0.7	4	4	1.0
0.4-0.0	20	8	2.5	20	10	2.0	17	9	1.9	10	5	2.0	5	2	2.5
p(trend)	.00001			.001			.005			.01			.03		

Low T4 count (p=.0006) or high neopterin (p=.02) predicted AIDS ≥3 years, high B2 level ≥2 years (p=.04) before diagnosis. Cox regression revealed independence of T4/T8 and neopterin (p=.01).
Conclusion. The earliest predictor of AIDS in HIV-seropositive homosexual men was a low T4/T8 ratio, followed by T4 count and neopterin 1 year later. These findings may help to better assess prognosis and monitor treatment strategies in HIV infection.

M.A.0.47 HIV-1 p24 ANTIGENAEMIA AND LOSS OF ANTI-CORE ANTIBODIES ARE CORRELATES OF RAPID DISEASE PROGRESSION AND NOT OF DISEASE PROGRESSION PER SE.

De Wolf, Frank*, Lange J*, Houweling J**, Coutinho R*, van der Noordaa J*, Goudsmit J* et al. * Academic Medical Centre, University of Amsterdam and ** Municipal Health Service, Amsterdam, the Netherlands.

Objective. To study the natural history of HIV-1 infection in relation to serological and immunological profiles.
Methods. 199 asymptomatic HIV-1 antibody (HIV-Ab) seropositive and 76 HIV-Ab seroconverted homosexual men were prospectively followed for 39 months. Epidemiological and clinial data were collected and blood was sampled every 3 months.
Results. AIDS was diagnosed in 38 men (AIDS attack rate 20.8%). The AIDS attack rate in HIV core Ab positives was 12.1% vs. 31.0% in core Ab negatives; it was 13.3% in HIV-1 p24 antigen (HIV-Ag) negatives vs. 53.9% in HIV-Ag positives, and it was 10.9% in those with CD4+ cell counts > 0.5 x 10^9/L vs. 49.9% in those with CD4+ counts < 0.5 x 10^9/L. AIDS attack rates after 30 months follow-up have been previously reported (De Wolf et al. J Infect Dis 1988;158:615-22), and were as follows: 6.0% in core Ab+, 35.7% in core Ab-, 6.9% in HIV-Ag-, 43.9% in Ag+,6.1% in those with CD4+ cell counts > 0.5 and 51.9% in those with counts < 0.5.
Conclusions. With longer follow-up the relative importance of absence of core Ab, presence of HIV-Ag, and (less so) of CD4+ cell counts < 0.5 x 10^9/L as predictors of AIDS has declined. Absence of core Ab and presence of HIV-Ag are predictors of rapid disease progression rather than of disease progression per se.

M.A.0.49 PSYCHOSOCIAL PREDICTORS AS CO-FACTORS FOR DISEASE PROGRESSION IN MEN INFECTED WITH HIV: THE SAN FRANCISCO MEN'S HEALTH STUDY.

Coates, Thomas J.*, Stall, RD*, Ekstrand, M*, Solomon, GF**
*Center for AIDS Prevention Studies, University of California, SF, CA, USA
**University of California, Los Angeles

Objective: To assess the contribution of psychosocial variables to disease progression in men infected with HIV.
Methods. Subjects were 198 men in the SFMHS infected with HIV (determined by ELISA and RIA), who in 1985 and 1987 completed psychosocial and behavioral interviews, physical exams, and analysis of lymphocyte subset analysis. Psychosocial variables included assessment of depression, losses of friends and lovers to the AIDS epidemic, social support, loneliness, primary relationship status, stress, work overload, and family and social support for a gay lifestyle. Behavioral variables included high risk sexual behaviors, sexually transmitted diseases, and drug and alcohol use. Physical exam assessed for signs and symptoms of HIV infection; AIDS was determined using CDC criteria. 1985 variables were used to predict disease progression in 1987 using multiple discriminant function analysis.
Results. Subjects were classified as symptomatic (diagnisis of AIDS or 2 or more AIDS prodromal symptoms + T-Helper cells <500)or asymptomatic (1 or fewer AIDS prodromal symptoms, T-Helper Cells >500, or both). All were asymptomatic in 1985; 28% (N=56) were symptomatic in 1987. Predictors of disease progression were lifetime sexual partners, lifetime sexually transmitted diseases, age of the subject, sexually transmitted diseases between 1985 and 1987. Conclusions. Secondary prevention might be enhanced through both behavioral (to reduce sexually transmitted diseases) and psychosocial interv.

L'annonce aux partenaires et la prévention de l'infection par le VIH
Partner Notification in HIV Prevention

T.A.0.1 PARTNER NOTIFICATION IN HIV PREVENTION

Chairpersons: Nathan Clumeck (Brussels, Belgium), Robert S. Remis (Montréal, Canada)

Panelists: John Gallwey (Oxford, United Kingdom), Jan Amil Kristoffersen (Skarer, Norway), Kathleen Toomey (Atlanta, USA), Fred Wolf (Denver, USA)

Although education is an important tool for preventing HIV transmission, its impact is slow and less than 100% effective. In addition, many persons exposed to HIV through sexual contact or needle-sharing may not perceive themselves to be at risk. The notification of sexual and needle-sharing partners of HIV-seropositive persons provides an opportunity to personalize the risk for exposed partners through information, counseling and testing and, in turn, to interrupt the chain of transmission. Preliminary evidence suggests that this approach may be feasible, acceptable and effective, at least in certain settings. Nevertheless, many questions remain concerning the place of partner notification in HIV prevention. Important issues include: the mechanism to access index cases, legal and ethical constraints, criteria for selective notification, criteria for partner selection (duration and timing of contact, adequate locating information), operational issues (staffing, training and quality assurance) and the determination of efficacy. Six panelists will provide a world perspective on current policies and programs, addressing the rationale, obstacles and opportunities for effective partner notification.

Surveillance du SIDA
AIDS Surveillance

T.A.0.2

THE IMPACT OF THE REVISED DEFINITION ON AIDS CASES DIAGNOSED IN MASSACHUSETTS: A PRELIMINARY ANALYSIS

Heinze-Lacey, Beverly*; Day, J.**; Seage, G.*; Oddleifson,S.*; Makarewicz, L.**; *Boston and **Massachusetts AIDS Surveillance Programs (BMASP), Boston, Massachusetts, USA

OBJECTIVE. To assess the disease and diagnosis trends associated with the latest revision (September 1987) of the CDC AIDS case definition.
METHODS. Cases diagnosed in 1988 and reported through December 1988 to BMASP were analysed. AIDS-related diseases were coded into mutually exclusive categories to assess cases meeting only the new disease and diagnostic criteria.
RESULTS. Of 564 cases, 430 (76%) met the pre-1987 definition. Eleven percent (60/564) met only the new disease categories: 3% dementia alone; 4% wasting alone; 2% M. tuberculosis (TB) alone; 2% had either other mycobacteria, salmonella, candida of the lung, or both wasting and dementia. Thirteen percent (74/564) were presumptively diagnosed, with pneumocystis pneumonia being most commonly reported (26/74, 35%). Of 319 homosexual men (HM), 51 (16%) met the new criteria vs. 45/125 (36%) IV drug users (IVDU), (p<.001) and 38/120 (32%) all other risk groups (ORG) (p<.001). Significantly more (p<.001) IVDU (17%) and ORG (13%) were diagnosed with only wasting, dementia, or TB when compared to HM (4%). Of 24 female IVDU, 15 (62%) met the new criteria vs. 30/101 (30%) male IVDU (p<.01). No differences were found by race.
CONCLUSION. In 1988, 134 cases met only the revised definition, a 31% increase in cases associated with the revision; it is unknown how many of these may eventually be definitively diagnosed. Sixty cases met only the new diseases categories, a 14% increase. IVDU, particularly female IVDU, and ORG cases were more likely than HM to be diagnosed using the new criteria.

T.A.0.3

L'IMPACT DE LA NOUVELLE DEFINITION DE SIDA A BARCELONE: LE ROLE DE LA TUBERCULOSE.

Caylà Joan A, Plasencia A, Batalla J, Parellada N, Jansà JM.
Institut Municipal de la Salut. Barcelona. Spain.

Objectif. Evaluer l'impact de la nouvelle définition du SIDA des CDC, et étudier les changements que cette définition comporte dans une ville avec une prévalence de tuberculose relativement élevée.

Méthodes. Le Service d'Epidémiologie et de Statistiques Vitales de l'Institut Municipal de la Santé de Barcelone enregistre les cas de SIDA et de tuberculose (maladies a déclaration obligatoire) notifiés par les médecins, et de plus réalise une recherche active sur les cas de ces deux maladies qui n'aient pas été notifiés.

Résultats: En 1987, chez les résidents à la ville, il y a eu 834 cas de tuberculose (taux d'incidence annuelle (TIA) de 49.0/100.000) et 113 de SIDA (taux de 6.6/100.000) selon l'ancienne définition des CDC, tandis que en 1988 on a identifié 943 cas de tuberculose (taux de 55.0/100.000) et 177 de SIDA (taux de 10.4/100.000) selon la nouvelle définition des CDC.
Jusqu'au 31.12.1986, parmi les cas de SIDA, 46.3% étaient homosexuels et 38.9% étaient toxicomanes par voie intraveineuse, mais avec la nouvelle définition des CDC, cela a changé: ainsi, en 1988, 58.1% des malades de SIDA sont toxicomanes par voie intraveineuse et 30.6% homosexuels masculins. L'incorporation de la nouvelle définition a supposé également une augmentation importante des cas de SIDA (36.3% en 1987-1988).
Dans ces résultats la tuberculose joue un rôle très important car la plupart de ces nouveaux cas apportés par la nouvelle définition (86.4%) correspondent à tuberculose extrapoulmonaire, cette maladie étant beaucoup plus fréquente chez les toxicomanes que chez les homosexuels (odds ratio = 4.58, IC = 2.25-9.33). Parmi les cas de SIDA, les toxicomanes se caractérisent, aussi, par une âge plus jeune que les homosexuels (moyenne de 27.06 ans versus 39.0, p< 0.001) et par avoir été plus fréquemment en prison (odds ratio = 29.7, IC = 7.23-129.8).

Conclusion. Ces résultats soulignent l'importance croissante des toxicomanes par voie intraveinouse parmi les cas de SIDA à Barcelone, tout spécialement dû à la maladie tuberculose. Les difficultés notoires pour obtenir des toxicomanes qu'ils suivent correctement la chimiothérapie ou la chimioprophylaxie contre la tuberculose, obligent à redoubler les efforts afin de développer des nouvelles stratégies face à ce nouveau problème.

T.A.0.4

IMPACT OF THE 1987 REVISION OF THE AIDS CASE DEFINITION IN THE UNITED STATES

Selik, Richard; Buehler, J.; Karon, J.; Berkelman, R.
Centers for Disease Control, Atlanta, Georgia, USA.

Objective. To measure the impact of the 1987 expansion of the AIDS case definition on the numbers and characteristics of reported cases in the United States.
Methods. For cases diagnosed since the revision and reported through 1988, we analyzed the proportion meeting only new criteria by quarter-year and demographic and other characteristics. We also compared the distribution of characteristics in cases meeting only new criteria and those meeting old criteria.
Results. In the 28,920 cases diagnosed and reported since the revision, the proportion meeting only new criteria was 28% overall, increased quarterly from 26% to 31%, ranged from 0% to over 70% in different states and territories, and was higher in women (38%) than in men (28%), higher in children (36%) than in adults (28%), higher in Hispanics (36%) and blacks (non-Hispanic) (33%) than in whites (non-Hispanic) (23%), and higher in heterosexual intravenous drug abusers (IVDAs) (43%) and lower in homosexual male non-IVDAs (21%) than in other exposure categories. The distribution of characteristics in cases meeting only new criteria differed from that in cases meeting old criteria:

Criteria	Women	Whites	Blacks	Hispanics	Heterosexual IVDAs	Homosexual non-IVDAs
Old (N=20,876)	9%	59%	26%	14%	18%	63%
New Only (N=8,044)	14%	45%	34%	21%	35%	43%
Total (N=28,920)	10%	55%	28%	16%	23%	57%

Conclusion. The revision has increased the numbers of reported cases nonuniformly over time and in different demographic and exposure categories, complicating analysis of trends in both the numbers and characteristics of cases.

T.A.0.5

MARKED UNDER REPORTING OF CDC DEFINED AIDS DUE TO POOR UTILIZATION OF THE HIV ANTIBODY TEST.

Andrew Masterson, A. Oppermann, S.Landesman., Kings County Hospital Center and SUNY Health Science Center at Brooklyn, Brooklyn, New York, USA.

OBJECTIVE: To determine the number of patients who would have received a CDC AIDS diagnosis if HIV antibody testing had been performed.
METHODS: All patients included in this study were in-patients, for at least 24 hours, at a major inner city public hospital between 1/1/88 and 12/31/88. HIV antibody testing was accessible to all patients, but not offered.
RESULTS: During 1988 there were 192 AIDS cases reported to the CDC from the aforesaid hospital. During the same period 91 patients were diagnosed with diseases that, along with a positive HIV antibody test, would have qualified for reportable CDC AIDS. None of the 91 patients had an HIV antibody test performed. All 91 patients had CDC defined risk factors: 33 had presumptive PCP, 31 had presumptive Toxoplasmosis, 7 had presumptive Esophageal Candidiasis, 6 had Wasting Syndrome, 4 had Extra Pulmonary TB, 2 had recurrent Non-typhi Salmonella Septicemia, and 1 had persistent Isosporiasis. An additional 7 had at least two of the above stated presumptive diseases.
CONCLUSIONS: The number of reportable CDC AIDS cases would have been increased by more than 40% had HIV antibody testing been performed. Thus 1) Lack of inclusion of these cases leads to significant under reporting of the disease. 2) Lack of inclusion of these cases results in a decrease in reimbursement to the hospital. 3) Lack of a CDC AIDS diagnosis prevents patients from qualifing for greatly needed social services.

T.A.0.6

EVALUATION OF AIDS SURVEILLANCE IN SWITZERLAND: ESTIMATION OF UNDERREPORTING AND IMPACT OF ACTIVE SURVEILLANCE

Engel,Robert*;Minder,C.*;Spuhler,T.**;Paradis,H.*;Samuel,M.*;
Somaini,B.* et al.
Federal Offices *of Public Health, **of Statistics, Bern, Switzerland

Objective.To determine completeness of reporting AIDS cases and the impact of the active surveillance system introduced in December 1987.
Methods.All death certificates (DC) inidcative of AIDS or HIV between 01-1985 and 06-1988 were reviewed and matched to reported AIDS cases.DC were analysed and underreporting (UR) was assessed by the Chandrasekaran and Deming Method. For DC between 12-1987 and 06-1988 that could not be matched,investigations on medical history were performed.The impact of active surveillance was investigated by analysing reporting sources,controlled for type of CDC definition.
Results.Of 235 deaths,210 (89.4%) could be matched to DC.The calculated UR based on deaths between 01-1985 and 06-1988 was 24.8%.For deaths between 12-1987 and 06-1988 the predicted UR was confirmed by reviewing medical records. The raise in reports since December 1987 (begin of active surveillance) was greatest for cases meeting only the criteria of the revised CDC AIDS definition.
Conclusion: Evaluation of a surveillance system is crucial for the interpretation of its data.The high percentage of deaths that could be matched to DC is thought to be due to the anonymous nature of both,reports of AIDS cases and DC.UR was substantial in Switzerland for cases diagnosed before mid 1987. The active surveillance pursued since 12-1987 generates more thorough report.

T.A.0.7

UNDERREPORTING OF MINORITY AIDS DEATHS IN THE SAN FRANCISCO BAY AREA, 1985-1986

Chu, G.*; Trachenberg, A.I.**; Hearst, Norman*; Riordan, N.*; Creeger, J.** and Sorensen, J.*, et al.
*Center for AIDS Prevention Sudies, University of California, San Francisco, USA;
**California Department of Health Services, Office of AIDS, Sacramento, USA.

Objective. To determine the completeness of reporting of AIDS deaths among Blacks and Hispanics in the five San Francisco Bay Area counties in 1985 and 1986.
Methods. Death certificates listing AIDS as a cause of death were identified using vital statistics data. Hispanic status was determined using surname and birthplace of both decedent and parents. Deaths were cross-checked with reported cases in the California State AIDS registry (part of the Centers for Disease Control AIDS Reporting System) current to May 6, 1988.
Results. Overall, 225 deaths were identified from death certificates. Of these, 168 (74.7%) matched with entries in the AIDS registry. Nonmatches were 15 deaths (6.7%) not listed in the registry at all (Category A in the table), 20 (8.9%) listed in the registry as still living (Category B), and 25 (11.1%) incorrectly listed as being white (Category C). Three deaths were in both of the latter two categories.

	Deaths Identified	Nonmatches	Category A	Category B	Category C
1985 Blacks	38	7 (18%)	2	2	3
1986 Blacks	70	13 (19%)	5	7	1
1985 Hispanics	47	10 (21%)	1	4	7
1986 Hispanics	70	27 (39%)	7	7	14

Conclusion. Minority AIDS deaths may be substantially underreported, even from an area considered to have a good AIDS reporting system. Racial misclassification, especially for Hispanics, appears to be a major problem. The situation did not improve from 1985 to 1986. Further data for minorities (including Asians) and data for whites will also be presented.

Infections par le VIH chez les consommateurs de drogues par voie intraveineuse
HIV Infection in IVDUs

T.A.0.8

TRENDS IN HIV SEROPREVALENCE AND RISK BEHAVIOR AMONG DRUG TREATMENT PROGRAM ENTRANTS

Farley, Thomas*, Peterson L.*, Cartter M.**, Hadler J.**
*CDC, Atlanta, GA **Connecticut Dept. of Health Services, Hartford, CT USA

Objective. To study trends in HIV seroprevalence, risk behavior and concern about AIDS among intravenous drug users (IVDU) entering methadone maintenance (MM) programs.
Methods. Seroprevalence/risk behavior studies of Connecticut MM program entrants have been carried out over two time periods: from April 1986 to March 1987 and from July 1987 to the present. We compared data from 222 IVDU entering four MM programs in the first study period to those of 355 IVDU entering the same programs from July 1987 to June 1988.
Results. Overall HIV seropositivity among IVDU who consented to testing was 17% (30/181) in the first study period and 15% (42/285) in the second period. Reported needle sharing in the month before entry decreased from 62% (137/221) in the first period to 44% (156/351) in the second period (p<.0001). This decrease persisted when the data were stratified by age, race, sex, clinic site, history of previous drug treatment or number of drug injections per day. Reported use of bleach to clean needles increased from 12% to 38% (p<.0001). IVDU in the second study period showed more concern about HIV transmission through needle use than through sexual practices: 85% (303/355) reported sharing needles less frequently because of AIDS, however 39% (137/355) reported having fewer sexual partners, and only 9% (33/355) used condoms "often" or "always".
Conclusions. IVDU entering MM programs in Connecticut show evidence of decreasing their HIV risk behavior. Seroprevalence remains stable.

T.A.0.9

NEEDLE EXCHANGE IN CENTRAL LONDON: ONE YEAR FOLLOW UP

Hart, Graham*; Carvell, A.*; Woodward, N.**; Johnson, AM.*; Parry, J.+; Adler, MW.*. *University College and Middlesex School of Medicine; **Bloomsbury Health Authority; + PHLS, London, England.

Objective. To evaluate the busiest needle-exchange for injecting drug users(IDUs) in the UK, in terms of its efficacy in reducing shared use of injecting equipment and preventing transmission of HIV infection.
Methods. Attendance rates (Oct '87-Nov '88) were monitored, as were syringes dispensed and returned. A sample of clients were interviewed, first at 1 month then again 3-4 months after entry to the scheme, regarding injecting and sexual behaviour. Saliva samples were tested for anti-HIV.
Results. On av 257 IDU's attended monthly, and made 762 visits per month. An av 8950 syringes were dispensed per month, 6918 returned; return rate 77%.

Recent Equipment Sharing (Last 1 month) and Sexual Behaviour (Last 3 months)

	1st Interview	2nd Interview
Borrowed equipment	15% (18/121)	9% (6/70)
Lent equipment	13% (16/121)	7% (5/70)
Sexually active	76% (92/121)	73% (51/70)
Used condoms	48% (44/92)	35% (18/51)

Saliva samples were donated by 109 clients, of which 7(6%) were ab+. A 2nd sample was provided by 60/109 3-4 months later; a further 2 were ab+ (a rise to 8%). Ab+ clients shared equipment with twice as many IDUs as ab- clients.
Conclusions. This scheme attracted and retained clients, its syringe return rate improved (Nov-Apr 66%; May-Oct 84%) and fewer clients had shared equipment on second interview. However condom use fell, and anti-HIV prevalence rose from 6%-8%. Continuing health education is indicated.

T.A.0.10

SEROPREVALENCE OF HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION AMONG INTRAVENOUS DRUG USERS (IVDUs) IN THE U.S.

David M. Allen*; Onorato, I.M.*; Sweeney P.*; Jones T.S.*; and State and local Health Departments. *AIDS Program, Centers for Disease Control (CDC), Atlanta, Ga., U.S.A.

Objective: To determine HIV seroprevalence among IVDUs entering drug treatment in the United States.
Methods: In 1988 and 1989, CDC in association with state and local health departments are conducting blinded surveys among IVDUs entering drug treatment. After testing blood for routine purposes, individual identifiers were removed and consecutive sera were tested for antibodies to HIV. Demographic information, (sex, age group, race and ethnicity), type of treatment program, and the primary drug used will be collected on over 22,000 IVDUs representing 44 clinics in 29 metropolitan areas.
Results: Preliminary results from 7 metropolitan areas show that HIV seroprevalence among IVDUs entering drug treatment ranged from 0% to 42.7%. Infection rates were higher in more densely populated metropolitan areas than in less densely populated areas. IVDUs who primarily used cocaine had a higher HIV seroprevalence (14.2%) compared to all other drugs (9.1%). HIV seroprevalence was higher among African-Americans than among whites (12.7% vs. 5.2%), but varied in different metropolitan areas.
Conclusion: These data suggest that continued efforts are needed to reduce the spread of HIV infection associated with IV drug use among African-Americans and in selected metropolitan areas. In areas with lower HIV seroprevalence there is a need to develop innovative programs to prevent the introduction and further spread of HIV among IVDUs.

T.A.0.11

SEROCONVERSION FOR HIV IN INTRAVENOUS DRUG USERS IN SAN FRANCISCO

Moss, Andrew R.*; Bachetti, P.*; Osmond D.*; Meakin, R.*; Keffelew, A.*; Gorter, R.*.
*University of California, San Francisco/SF General Hospital, California, USA.

Objective. We examined changing HIV seroconversion rates over time in intravenous drug users in treatment in San Francisco who have been studied more than once since 1985.
Methods. IVDUs in methadone and detoxification treatment programs in San Francisco have been offered anonymous HIV testing with notification of results since mid-1985. Unique identifiers are obtained and repeaters are identified. 380 IVDUs were identified as having been studied at least twice during 1985-1988. We examined seroconversion in this group.
Results. 11/380 IVDUs studied twice seroconverted over 421 person-years, or 2.6% per person-year (ppyr). Rates by ethnic group were white 1.8% ppyr, black 5.7% ppyr, hispanic 3.6% ppyr. The overall seroconversion rate fell over time from 7% ppyr in 1985 to 2.4% ppyr in mid-1987 and has remained roughly constant since. 7 seroconverters were female and 4 were male; all had used intravenous cocaine at least weekly in the previous year. The average rate of 2.6% ppyr corresponds to 300 new infections/year in this population in San Francisco, compared with 0.5% or about 100 infections/year in homosexual men.
Conclusion. Following the introduction of voluntary testing, methadone slots for seropositives and outreach and bleach distribution programs, seroconversion of IVDUs in treatment fell to 2.4% per year. The rate has remained stable at this level since mid-1987, so that additional interventions are now required.

T.A.0.12

RISK FACTORS FOR HIV-1 INFECTION AMONG STREET-RECRUITED INTRAVENOUS DRUG USERS IN NEW YORK CITY

Friedman, Samuel R.*, Rosenblum A*, Goldsmith D*, Des Jarlais DC**, Sufian M*, et al
*Narcotic and Drug Research Inc, NY, NY, USA; **NY State Div. of Substance Abuse Services, NY, NY, U.S.A.

Objective. To determine whether risk factors for HIV-1 seropositivity among street-recruited IV drug users (IVDUs) are similar to those reported in analyses based on drug abuse treatment samples. Since almost all reported studies are based on treatment samples, it is important to determine whether IVDUs recruited in other ways have similar risk factors.
Methods. Sera and interviews were collected in 1987 from 256 IVDUs recruited in areas of active drug use in Queens and the Bronx. Antibody testing used repeat ELISA with 100% Western blot confirmation.
Results. 53% were seropositive. Drug injection frequency is a significant predictor of seropositivity. This is primarily a function of cocaine injection. 5/16 (31%) of subjects who had injected only heroin during 1983-86 and 23/37 (62%) who had injected only cocaine were seropositive (p < .05). 4/18 (22%) who had begun injecting within the previous 5 years and 132/238 (55%) longer-term injectors were infected (p < .01). By crosstabulation, use of cookers after others, injecting in shooting galleries, frequency of injecting speedball (mixed heroin and cocaine), self-reported STD history prior to 1975, age (< 30 years), and non-Latino ethnicity, are each significantly related to seropositivity. In stepwise multiple logistic regression, cocaine and speedball injection frequencies, injection for 5+ years, non-Latino ethnicity, and recruitment in the Bronx are significant predictors of seropositivity.
Conclusion. Seroprevalence in the street sample was approximately the same as has been reported in treatment samples in NYC. Injection frequency, cocaine injection, ethnicity, and geographical location have all previously been shown to be risk factors for HIV-1 infection in NYC drug treatment samples. This suggests that, in a city in which HIV-1 has been present among IVDUs a long time, street and treatment samples show similar patterns of infection. Separate studies are needed in cities where the epidemic is more recent. The finding that IVDUs are less likely to be infected for 5 years after beginning to inject makes public health interventions targeting new injectors both feasible and urgent.

T.A.0.13

HETEROSEXUAL BEHAVIOR OF INTRAVENOUS DRUG USERS.

Hoek, Anneke van den; Haastrecht BJA van, Coutinho RA.
Municipal Health Service, Amsterdam, The Netherlands.

Objective. To determine the potential role of intravenous drug users (IVDU) in the heterosexual transmission of HIV by studying sexual techniques and condom use practiced with steady, casual and commercial partners.
Methods. Between Sept. '88 and Jan. '89, 209 IVDU (112 ♂ and 97 ♀) participating in a HIV-study have been interviewed by standard questionnaire about their sexual behavior in the prior 3-6 months.
Results. The mean age was 30.6 years (SD 5.4). Infected with HIV was 38%. 97/209 IVDU (59 ♀ and 38 ♂) reported a steady partner of whom 38% was non-IVDU, The mean number of sexual contacts was 2.8/week. 41 participants (27 ♂ and 14 ♀) had 92 casual relations of whom 67% was non-IVDU. 53 women worked as prostitutes with a mean number of 36 customers per month.
Table presents % using condom > 2/3 of the sexual contacts (s.c.) during specific sexual technique by type of relationship.

	steady partner		casual partners		customers
	% ♀	% ♂	% ♀	% ♂	% ♀
- vaginal s.c. with condom	23	28	25	29	90
- orogenital s.c. with condom	17	-	8	-	81

Vaginal intercourse was the most popular sexual technique in all relationships and anal s.c. was rarely practiced by only a few participants.
Conclusion. In most private sexual relations condoms are not or infrequently used with no difference between steady or casual partners. As 38% of the participants is infected with HIV, their potential role in heterosexual transmission - to IVDU and non IVDU! - may be considerable. Private partners appear more at risk than commercial partners.

Transmission sexuelle du VIH (partie 2)
Sexual Transmission of HIV (Part 2)

T.A.0.14 TRANSMISSION OF HIV IN EDINBURGH AMONGST HETEROSEXUAL INJECTION DRUG USERS (IDU).

*Susan J Davidson, JR Robertson, *RP Brettle. *Infectious Diseases Unit; Muirhouse Surgery, EDINBURGH, Scotland, U.K.

OBJECTIVE: Assessment of immunological and behavioural variables involved in transmission of HIV amongst heterosexual IDU in Edinburgh.
METHOD: Heterosexual couples with one HIV +ve index were recruited into a prospective study of heterosexual transmission. 6 monthly interviews recorded behaviour, plus clinical and immunological status.
RESULTS: To date 73 couples have been interviewed, with 19 female (F) and 54 male (M) index cases who all acquired HIV by IDU. 16 F and 4 M sexual contacts are also drug users. In these F contacts, despite a mean length of relationship (R) of 35(5-96) months, a mean of 19(0-60) months of unprotected intercourse (UI), a mean of 65(10-223) episodes of intercourse per year plus a mean of 43(12-70) months of IDU only 3(19%) have seroconverted. In the M contacts despite R of 42(2-139) months, UI of 24(2-60) months, a mean 112(70-167) episodes of vaginal intercourse per year and 47(14-62) months of IDU no transmission occurred. Transmission did not correlate with anal intercourse, past history of STD or barrier contraceptive use nor with absolute T4 count or clinical state of index. In couples whose only risk of transmission was heterosexual sex, transmission occurred in 16% from M to F and 5% F to M.
CONCLUSION: In double drug using couples exposed to 2 risk factors transmission is not greater than those only exposed to heterosexual sex. This is surprising, suggesting that other factors such as variability in infectivity of the index or susceptibility of the contact to infection may be important.

T.A.0.15 Co-Factors in the Heterosexual Transmission of HIV in West Germany

S. Staszewski, S. Rehmet, E.B. Helm, W. Stille, Zentrum der Inneren Medizin, Universitätsklinik Frankfurt, Fed. Republic of Germany.

Objective: To investigate heterosexual HIV transmission frequency as well as co-factors in favour of transmission.
Method: We examined 133 heterosexually active couples, of whom at least 1 partner was positive for HIV (index person), and who had had sexual contacts without barrier contraceptives until first examination.
Results: Of 129 index persons (81 males, 48 females), 27 (21%) had infected their partners (n=28). A comparison between those (= IPP), and those not having infected their partners (IPN) showed a significant difference as to frequency of positive TPHA and extent of cellular immunodeficiency. 27% IPP, but only 14% IPN showed a positive lues serology. 46% IPP, but only 18% IPN had a CD4 cell count <200. On the other hand, 31% IPN, but only 4% IPP, had CD4 >800. Moreover, until now, 33% IPP, but only 8% IPN, have developed full-blown AIDS. The investigation of the above mentioned index persons' sexual partners showed a significant difference in infection rates of men and women. Of the 84 female sexual partners, 26 (31%) were infected, but only 2 (4.1%) of the 49 male partners.
Conclusion: Transmission rates from female to male are higher than vice versa. Persons with fast progressing disease seem to be more infectious than persons with stable conditions.

T.A.0.16 HETEROGENEOUS MALE-TO-FEMALE TRANSMISSION OF HUMAN IMMUNODEFICIENCY VIRUS.

Padian, Nancy*, Shiboski, S.*. *University of California, San Francisco, California, USA.

Objective: To examine recent observations that number of sexual contacts is unrelated to transmission and to assess evidence for heterogeneous rates of heterosexual transmission.
Methods: Using data from a study of opposite sex partners of individuals infected with HIV, we examined the association between number of contacts and other risk factors for transmission. To account for unkown infection dates in the index case, reported number of contacts was adjusted by estimating dates of seroconversion and counting only those contacts after this date. 153 women who were sexual partners of infected men were examined: 24% were infected.
Results: The logarithm of the adjusted number of contacts is associated with transmission (p=.001) and remained significant after adjusting for four previously significant risk factors (race, anal intercourse, bleeding from trauma during sex, and not using condoms). An interaction between number of contacts and condom use provided evidence of different transmission rates between couples who did and did not use condoms.
Conclusions: Number of contacts is associated with infection, but in a nonlinear fashion. Variation in the number of contacts necessary for transmission can be attributed to the hypothesis that contacts are mediated by condom use and heterogeneity in susceptibility and infectiousness. Studies that did not find an association between number of contacts and transmission may have only considered a linear relationship, may have misclassified exposures, or may not have examined the sources and effects of heterogeneous transmission rates.

T.A.0.17 RISK FACTORS FOR HIV TRANSMISSION IN STEADY HETEROSEXUAL COUPLES.

Seidlin, Mindell; Dugan, T; Vogler, M; Bebenroth, D; Krasinski, K; Holzman, R. New York University, New York, U.S.A.

Objective. To assess the determinants of HIV transmission in heterosexual couples.
Methods. Eligible partners(P) had never used IV drugs and had ≥ 10 episodes of vaginal intercourse (VI) with an infected index case (I). All Ps and available Is were interviewed about sex, reproductive and drug behavior, & tested for antibody to various DNA & RNA viruses, P24 antigen; CD4 cells; and VDRL reactivity. Risk ratios were calculated by logistic regression.
Results. 61 Ps (56 female) and 29 Is (4 female) were enrolled. 31 Ps were HIV+ and 28 were HIV–; 2 Ps had inconclusive tests. HIV+ and – Ps did not differ significantly in median age, race, marital status, length of relationship with I and episodes of VI, number of lifetime sex partners, age of first intercourse, sex during menses, history of alcohol use, and presence of antibodies to EBV, CMV, and HSV1. P's serostatus was not related to their I's risk group or circumcision status.

	RR For HIV seropositivity	
Variable	Univariate(95%CI)	Adjusted for other variables
Crack	13.16 (1.35,111.89)	5.42 (0.50, 58.96)
Other NonIV Drugs	0.88 (0.29, 2.70)	0.70 (0.13, 3.86)
Any Anal intercourse	3.11 (1.04, 9.32)	8.28 (1.31, 52.22)
HSV2 antibody	3.30 (0.64, 17.96)	3.34 (0.44, 25.04)
Hstry genit. ulcer	3.35 (0.90, 12.47)	1.41 (0.40, 4.96)
Fellatio	0.36 (0.08, 1.52)	0.06 (0.007, 0.47)

Conclusions. In these 61 couples, prevalence of HIV seropositivity in the partner of an index case was related most strongly to crack use and to anal intercourse.

T.A.0.18 SMOKING AS A RISK FACTOR FOR HETEROSEXUAL TRANSMISSION OF HIV-1 IN HAITIAN WOMEN

Halsey, Neal*; Boulos, R**; Holt, E*; Quinn, TC*; Brutus, JR**; and Ruff, A*; et al.
*Johns Hopkins University, Baltimore, MD, USA, **Centers for Health and Development, Port-au-Prince, Haiti

Objective. To identify risk factors for HIV-1 infection in pregnant Haitian women.
Methods. Women residing in an impoverished urban community were interviewed and tested for HIV-1 and syphilis.
Results. Of 1,953 women tested, 179 (9.2%) were seropositive for HIV-1. Higher HIV-1 seropositivity rates were associated (p<0.001) with being unmarried, positive serology for syphilis, lower economic status, and smoking. Smoking women had an 18.4% seropositivity rate vs. 8.6% for non-smokers (p=0.0004).

Women who smoked 6 or more cigarettes per day had a higher rate than women who smoked 1-to-5 times per day (31.0% vs 14.1%, p=0.04). Logistic regression analysis revealed that smoking was a significant predictor (OR=3.2, 95% CI 1.7-6.2) of HIV-1 seropositivity independent of all other factors.
Conclusions. Smoking has been associated with increased risks of herpes simplex virus type 2 and papillomavirus infections, and cervical lesions in other studies. We postulate that smoking may increase susceptibility to HIV-1 infection either directly through effects on the cervix or indirectly by increasing the risk of other infections that disrupt cervical epithelium.

T.A.0.19 RISK FACTORS IN HETEROSEXUAL TRANSMISSION OF HIV

Paolo Costigliola*, E.Ricchi*, B.Marinacci*, V.Colangeli*, M.C.Re**, F.Chiodo*.
*Istituto Malattie Infettive -**Istituto di Microbiologia; Universita' di Bologna, Bologna, ITALY

Objective: To assess the risk factors in HIV heterosexual transmission evaluated by a cohort study on stable partners of HIV infected subjects.
Methods: From 1985 to 1988 we have examined 197 heterosexuals which have had stable relationship (at least for 9 months) with HIV Ab +ve subjects. All the partners (64 males and 133 females) had not other current or previous risk factors of acquiring HIV infection (i.v. drug addiction, homosexual practices and transfusions). All subjects underwent HIV serology (ELISA & WB) and 93 of them answered a questionnaire about sexual habits, e.g. "safe-sex" and sexual intercourse behavior. A cohort of HIV Ab negative partners took a part in a follow-up program; they complied to repeat HIV Ab tests and epidemiological interview every 6 months. This longitudinal study involved 86 partners, who were HIV Ab negative at first analysis, during an average period of 28 months.
Results and Conclusion. Ten/64 (15.6%) male and 29/133 (21.5%) female partners were found to be HIV Ab positive at the beginning of this study, and the difference between male-to-female and female-to-male rate is not statistically significant. Length of relationship, frequency in sexual contacts, vaginal intercourse, and anal sex for females, they all seem to be the most important factors in HIV contagion. The epidemiological analysis of seroconverted partners outlines the same results. Still we see all seroconversions happened in 9/54 partners (16.6%) and they occurred among couples which didn't use condoms regularly (< 50% of sexual contacts).

Efficacité et évaluation des programmes
Programme Effectiveness and Evaluation

T.A.0.20

SAFER INJECTION AMONG PARTICIPANTS IN THE FIRST NORTH AMERICAN SYRINGE EXCHANGE PROGRAM

Des Jarlais, Don C.*; Hagan, H. **; Purchase, D.***; Reid, T.** and Friedman, S.R. ****.

*New York State Div of Substance Abuse Services, New York, NY, USA, **Tacoma- Pierce City Health Dept., Tacoma, Washington State, USA, ***Point Defiance AIDS Project, Tacoma, Washington State, USA, ****Narcotic and Drug Research, Inc., New York, NY, USA.

OBJECTIVE: Syringe exchanges (SE's) to prevent HIV infection among IV drug users are widely used in Europe, but only recently have been established in North America. We examined changes in the use of drug injection equipment among participants in the first North American SE, in Tacoma, WA.
METHODS: 46 participants were randomly selected and interviewed about their drug injection practices for the one month prior to beginning the SE and for the month prior to the interview (while participating in the exchange). The subjects had been participating in the SE for an average 3 months. 70% were male, 61% White, 17% Black, 9% native American, 8% Latino/Hispanic, 2% Asian and 2% not specified. Mean age was 33 years. The various risk behaviors were measured in frequency per month, and t-tests were used for statistical testing. (The study is ongoing, and data from additional subjects will be available by the time of the conference.)
RESULTS: Although there was considerable variation across individuals, all measures showed change towards "safer" injection. Lending injection equipment to a sexual partner or close friend declined from a mean of 64/mo. to a mean of 44/mo. (p<.05), lending equipment to a casual friend from 48/mo. to 32/mo. (p<.05), renting used equipment from 29/mo. to 18/mo. (ns), borrowing equipment from 31/mo. to 24/mo. (ns), and using only water to clean equipment from 102/mo. to 70/mo. (ns). Use of bleach to clean equipment increased from 71/mo. to 130/mo. (ns).
CONCLUSION: Participation in the SE was associated with substantial reduction in AIDS risk behavior, similar to European findings. Also similar to European findings, there was an important residual of risk behavior that may require interventions beyond the syringe exchange.

T.A.0.21

EVALUATION OF THE NEEDLE EXCHANGE PROGRAM IN AMSTERDAM

Hartgers, Christina; Buning, EC and Coutinho, RA.
Municipal Health Service, Amsterdam, The Netherlands

Objective. To study the impact of participation in the needle exchange
program on drug use behavior.
Methods. In 1987 145 IVDU's were interviewed of whom 60 (39%) were seen for
follow-up in 1988. Differences between "exchangers" (participants of the
exchange program) and "non-exchangers" were studied regarding demographic
and drug use behavior.
Results. Those who had foreign nationality were more often lost to follow-
up. The follow-up group as a whole moved in the direction of more safe in-
jecting behavior, which was primarily accounted for by risk reduction in the
group of non-exchangers. However, as in 1987, exchangers in 1988 still were
at a significantly lower risk level than non-exchangers (p<0.001). There was
no increase in i.v. drug use among the exchangers. 32% of the exchangers in
1988 said to inject irregularly the last 1/2 year vs. 70% of the non-exchan-
gers (p<0.05). A logistic regression on the 1987-data showed that 5 out of 13
variables were independently and significantly associated (in the mentioned
direction) with needle-sharing (borrowing) during the last 2 years: not daily
injecting, not exchanging needles, having volunteered for an AIDS-test, male
sex and young age.
Conclusions. Exchangers maintain their relatively low risk-level of i.v.
use over a long period of time. Using a needle exchange program seems to be
especially attractive to regular injectors and does not lead to an increase
in i.v. drug use. Those who inject infrequently are more likely to share
needles. Alternative preventive efforts - like education on how to clean
needles safely and effectively - may have to be directed at this group.

T.A.0.22

BRIEF COUNSELING TO REDUCE AIDS RISK IN IV DRUG USERS: UPDATE

Gibson, David R., Lovelle-Drache, J., Derby, S., Garcia-Soto, M., Sorensen, J. L., and Melese-d'Hospital, I.,
University of California, San Francisco, USA

Objective. We are evaluating the effectiveness of brief counseling designed
to reduce AIDS risk in intravenous drug users. Drawing on insights from
health psychology, the 55-minute counseling is a practical, nonstaff-inten-
sive intervention, which, if effective, could be widely disseminated. The
counseling features problem-solving of situations in which drug users are
tempted to share needles or engage in unprotected sex.
Methods. Eighty-eight IV drug users in heroin detoxification treatment were
randomly assigned to counseling or an information-only brochures condition.
Outcome measures include knowledge, perceived threat, anxiety, response effi-
cacy (acceptance of guidelines to reduce risk), self-efficacy and communica-
tion skill in arranging low-risk behavior, and self-reported needle-sharing
and unprotected sex.
Results. Sixty-eight (77%) and 63 (73%) were reached for post- and follow-up
interview 10 and 90 days after receiving counseling/brochures. Very few drug
users in either condition reported any needle-sharing at either measurement
point. At the postinterview, experimental (counseling) subjects scored 4/10
and 1/4 points higher on five-point drug-related measures of self-efficacy
(p=.05) and communication skill (p=.05), and reported using condoms 40% more
often (p=.004) and bleaching needles more often than subjects receiving bro-
chures. The self-efficacy finding was sustained at the follow-up interview;
counseling subjects also reported more sexual response efficacy (p=.01).
Conclusion. The counseling appears to have short-term positive consequences.

T.A.0.23

PLAN FOR THE PREVENTION AND CONTROL OF AIDS IN BASQUE COUNTRY.

Zulaica, D.; Elizalde, B.; Garcia Gurutzarri, A.; Zubia, I.; Urcelay, A., Servicio Vasco de Salud.Osakidetza.San Sebastian.Spain.

Objetive: Report on the Plan for Prevention and Control of AIDS in Basque Country 18 months after its inauguration.

Methods: The infrastructure of the plan consists of five persons: responsible phisician, an epidemiologist, a health educator, a nurse and an administrative. The program development was divided into three areas: a) information and education campaigns, b) organization of health care, c) activities to prevent discrimination of seropositive subjects, particularly in schools.

Results: Two large campaigns were carried out and evaluated.
a) Information and education campaigns: one oriented toward the general population to promote the use of condoms and other
protective measures, and the other designed to combat discrimination.
b) Organization of health care: The care of seropositives was structured at the primary
and hospital levels, which were coordinated through at-home care teams.
c) Anti-discriminatory activities: In schools, particulary, we have had serious problems
of integration of seropositive children. The policy of fully informing
school directives instead of withholding this information has been more positive. There
are now 11 seropositive children in the schools of the Basque Country.

Conclusion: In our opinion, the existence of regional programs, with unified criteria, messages and activities, expedites coordination and increases the effectiveness of efforts against AIDS.

T.A.0.24

INCREASING CONDOM SALES FOLLOWING AIDS EDUCATION, USA

Moran, John S*; James, MR**; Peterman, TA*; Stone, KM.*
*Centers for Disease Control, Atlanta, Georgia, USA,
**Nielsen Marketing Research, Northbrook, Illinois, USA.

In the fall of 1986, the US Surgeon General warned of the risk of Human
Immunodeficiency Virus (HIV) infection and recommended the use of condoms,
as well as other measures, to prevent sexual transmission.
Objective. To ascertain whether condom use increased in the US after the
Surgeon General recommended their use.
Methods. Sales data from a national probability sample of drug stores
(and, since 1986, food stores and mass merchandisers) were analyzed.
Results. Annual sales of condoms in drug stores rose 0.6% from 1983 to
1984, 1.2% from 1985 to 1986 and 20.3% from 1986 to 1987. The largest
sales increase occurred in early 1987:

BIMONTHLY CONDOM SALES BY DRUG STORES, FOOD STORES AND MASS MERCHANDISERS

	Plain Latex	Latex with Spermicide	Natural Membrane
Mar-Apr '87	32,134,000	5,949,000	3,288,000
Jul-Aug '87	36,361,000	8,847,000	3,382,000
Nov-Dec '87	32,896,000	8,766,000	3,333,000
Mar-Apr '88	35,452,000	9,801,000	3,036,000
Jul-Aug '88	38,722,000	12,249,000	2,976,000

Sales increased as much in areas of low AIDS incidence as in areas of
higher AIDS incidence where sales had already increased in 1986.
Conclusion. Latex condoms sales increased in the US after they were
recommended for the prevention of HIV transmission. The largest increase
was in latex condoms with spermicide. Concurrent with an increase in
latex condoms, sales of natural membrane condoms decreased.

T.A.0.25

EFFECTIVENESS OF CONDOM PROMOTION IN A NAIROBI COMMUNITY OF PROSTITUTES.

Plummer, Francis Allan*,***, Scarth, J.***, Ngugi, E.N.*,
Waiyaki, P.**, Ndinya-Achola, J.O.*, and Ronald, A.R.***, et al.
*University of Nairobi, Nairobi, Kenya, **Kenya Medical Research
Institute, Nairobi, Kenya, ***University of Manitoba, Winnipeg, Manitoba,
Canada.

Objective. To evaluate the frequency of condom use among a group of pros-
titutes and the impact of condom use on sexually transmitted disease (STD)
incidence.
Methods. Condom promotion and distribution was initiated in a community
of prostitutes in one Nairobi region in 1986. Condom use was evaluated by
interview of study group women (SGW) every 6 months. Newly enrolled women
served as controls (CW). The effect on STD transmission was determined
from monthly male STD incidence data by city region, using a region
similar to the index region (IR) as a control (CR).
Results. By March 1988, 100% of SGW (n=135) reported some condom use vs
78% of CW (n=36) ($p<10^{-6}$). The mean frequency of use was 77 ± 25% in SGW
vs 29 ± 29% in CW (p<.001). The most frequent reason for not using con-
doms was client reluctance. The mean monthly incidence of all STD among
IR men was 336 in 1981 and 134 in 1987, while the incidence in CR men was
573 in 1981 and 378 in 1987.
Conclusion. This program has achieved a durable increase in condom use
and may have resulted in reduced STD transmission.

Déclaration du VIH
HIV Reporting

T.A.0.26 SURVEILLANCE FOR HIV INFECTION IN MINNESOTA: RESULTS FROM THE FIRST THREE YEARS OF OPERATION.

MacDonald, Kristine*; Danila R*; Meier D*; Heiser J*; Stiepan D*; Osterholm M. *MN Dept. of Health (MDH), Minneapolis, MN U.S.A.

Objective. To ascertain the burden of medically detected disease caused by HIV infection (regardless of symptoms) in Minnesota.
Method. HIV infection became reportable to the MDH in October 1985. The reporting system was passive until January 1987, when active surveillance was implemented at all hospitals in the metropolitan Twin Cities area and at 6 sentinel hospitals in the remainder of MN. All clinical laboratories in the state also participate in laboratory-based surveillance.
Results. As of January 1989, 1487 cases of HIV infection have been reported by name. Current stages for cases are: Group I (acute infection) = 1; Group II (asymptomatic infection) = 531; Group III (peripheral generalized lymphadenopathy) = 119; Group IV (constitutional symptoms) without AIDS diagnosis = 103; Group IV with AIDS diagnosis = 467; and Unknown = 266. HIV cases without AIDS were more likely than AIDS cases to be nonwhite ($p < 0.001$), female ($p < 0.01$), and IV drug users ($p < 0.001$). Only 3 AIDS cases (0.6%) have been reported in persons less than age 20; whereas, 34 (3.7%) of 911 HIV-infected persons of known age were less than age 20 ($p < 0.001$). AIDS cases have been reported from 37 of 87 MN counties (42%); whereas HIV-infected persons (including AIDS) have been reported from 58 counties (66%) ($p < 0.001$).
Conclusions. While these data may be biased by diagnostic practices, they provide information on infection trends not available from AIDS surveillance alone. Such trend analysis is useful in monitoring the HIV epidemic.

T.A.0.27 HIV INFECTION REPORTING IN THE UNITED STATES

Stehr-Green, Jeanette; Berkelman, R.; VanPatten, B.; Curran J.
Centers for Disease Control, Atlanta, Georgia, USA

Objective. To summarize the status of HIV infection reporting in the U.S.
Methods. AIDS surveillance staff from each state were contacted in October 1988 regarding mandatory reporting of HIV seropositive persons and were asked to provide copies of reporting regulations and report forms.
Results. As of October 1988, 24 states had mandatory reporting of HIV infection. States with reporting had a lower cumulative incidence of AIDS than states without reporting (median of 299 cases vs. 765 cases) and reported 19% of all U.S. AIDS cases. Sixteen states (67%) require reporting by name and 17 (71%) require a positive result on a confirmatory test before reporting. Most states collect basic demographic data (age, sex, race, and place of residence) and almost half collect risk factor information. Four states (17%) collect sufficient information on the clinical status of the patient to use the CDC HIV infection classification system. Sixteen states (67%) use the data to monitor epidemiologic trends and 15 (63%) states use the data to initiate partner notification services.
Conclusions. Because reporting systems were developed independently, there is no standardized approach and results cannot easily be compared. Due to selection biases associated with testing, the inability to exclude duplicate reports in states that do not collect patient identifiers, and the lack of studies to determine the completeness of reporting, HIV infection reports alone cannot be used to monitor trends in HIV infection. HIV infection reporting must be rigorously evaluated to determine whether it meets surveillance and prevention objectives.

T.A.0.28 THE ROLE OF HIV INFECTION REPORTING IN PUBLIC HEALTH

Chairpersons: Ruth L. Berkelman (Atlanta, USA), Joel DeKoven (Toronto, Canada)
Panelists: Molly Coye (Trenton, USA), O. Noel Gill (London, United Kingdom), Fred Wolf (Denver, USA)

Some or all jurisdictions within at least 25 countries currently require reporting of HIV-infected individuals to public health officials. Following two accepted oral presentations on HIV reporting, panelists will reflect upon the objectives of the HIV reporting system in their local jurisdictions or countries, and how their system is designed to meet these objectives. Systems with and without confidential identifying information will be described; and the laboratory's role versus that of the health care provider will be discussed. Issues related to the role of notifiable disease reporting in supporting partner notification and other individual case management activities as well as the epidemiologic usefulness of data collected by different reporting systems will be addressed. In addition, the impact of HIV reporting, both positive and negative, on other prevention/control activities, including counseling and testing sites, will be explored. Rather than attempting to build a consensus, this workshop is specifically designed to provide a forum for the exchange of information on a controversial subject. It will attempt to explore how and why different jurisdictions may be best served by different approaches to HIV reporting and to define factors which should be considered when areas seek to adopt or modify HIV reporting regulations.

T.A.0.29 PROGNOSTIC INDICATORS FOR DEVELOPING AIDS WITHIN 24 MONTHS.

Alfred J. Saah, Munoz A, Fox R, Kaslow RA, Rinaldo C, Detels R, Phair JP.
The Johns Hopkins School of Hygiene and Public Health and the Multicenter AIDS Cohort Study (MACS), Baltimore, MD, USA.

Objective. To identify laboratory and clinical variables with predictive power for onset of AIDS above that provided by T helper (CD4+) number.
Methods. 1307 white MACS participants who were HIV-1 seropositive at baseline were seen every 6 months for at least 3.5 years. After stratifying by initial CD4+ number and percent decline in CD4+ number in the first 6 months, a Cox regression analysis was done to identify variables and changes in those variables that had independent predictive power for developing AIDS within 24 months.
Results. 170 men developed AIDS in the first 24 months of followup. Those who developed AIDS had, at baseline, significantly higher CD8+ lymphocyte counts (772 vs 682), lower hemoglobin(14.9 vs 15.2), higher IgA(333 vs 227), lower ratio to positive in the DuPont HIV ELISA(2.66 vs 2.83) and fewer platelets(225k vs 241k, p=0.09) than those who remained AIDS-free. Changes in the 6 mos. after baseline that were associated with developing AIDS included onset of an ARC-like symptom, a mean decline of 6k platelets, or 0.2g hemoglobin. DuPont ELISA ratio increased by 0.3 in those who did not develop AIDS, but remained unchanged in those developing AIDS.
Conclusion. In addition to number and rapidity of decline of CD4+ lymphocytes, a clinical profile of those who will develop AIDS within 2 years is now possible. Such data are helpful in patient management and in designing therapeutic trials.

T.A.0.30 CLINICAL COURSE OF PRIMARY HIV INFECTION : CONSEQUENCES FOR THE SUBSEQUENT COURSE OF THE INFECTION.

Pedersen, Court, Lindhardt BØ, Jensen BL, Lauritzen E, Gerstoft J, Dickmeiss E et al.
University of Copenhagen, Copenhagen, Denmark.

Objective. To investigate the impact of the clinical course of the primary HIV infection on the subsequent course of the infection.
Methods. A group of 86 individuals for whom the time of seroconversion for HIV could be ascertained within a time frame of 12 months were followed for a median of 670 (range 45-1506) days. Progression criteria were : 1) development of AIDS, 2) progression to CDC group IV. Life tables were used to compare disease progression.
Results. An acute glandular-fever-like illness occurred in 52% of the patients. The median duration of the illness was 16 days.
Progression rate to CDC group IV was 78% at three years for those who had a longlasting (>14 days) primary illness (n=27) compared to 10% for those who had minor symptoms or were symptom-free (n=59) (p<0.0001). The corresponding progression rates to AIDS were 23% and 0%, respectively (p=0.027).
Conclusion. The primary response to HIV infection may determine the subsequent course of the infection. Future studies should focus on the pathogenesis of acute HIV infection as it appears that a deliniation of the early events may provide the basis for a better understanding of the subsequent progressive immunodeficiency during HIV infection.

T.A.0.31 PROGRESSION TO AIDS IN THE SAN FRANCISCO GENERAL HOSPITAL COHORT STUDY

Moss, Andrew R.*; Bacchetti, P.*; Osmond, D.*; Brodie, B.*; Ross, E.*; Krampf, W.*.
*University of California San Francisco/SF General Hospital, California, USA.

Objective. We examined progression to AIDS over four years in HIV positive homosexual men.
Methods. 288 HIV AB+ men recruited 1983-84 were followed in the AIDS clinic at San Francisco General Hospital. We report progression to AIDS and ARC at four year of study, an estimated average seven years from infection.
Results. At 48 months the actuarial progression rate of HIV Ab+ subjects to clinical AIDS was 27% and to AIDS or ARC was 46%. For subjects with ARC the observed two-year progression rate to AIDS was 42%.
Progression rates to AIDS by no. of CD4 lymphocytes were: CD4<200 88%; 200<CD4<400 51%; CD4>400 21%. By Beta-2 microglobulin (Beta-2) they were: Beta-2>5.0 77%; 3.0<Beta-2<5.0 41%; Beta-2<3.0 15%. By p24 antigen they were: p24 present 68%; p24 absent 19%. In a model using these markers plus proportion of CD4 lymphocytes and hematocrit, rates by number of abnormalities were: 0 abnormalities 8%; one 24%; two 52%; three or more 86%. 75% of subjects without AIDS were abnormal on one or more markers at four years.
For subjects with ARC and one abnormal marker, two-year progression rates to AIDS were: ARC and CD4<400 89%; ARC and Beta-2>3. 91%; ARC and p24 present 85%.
Conclusion. Most seropositives in the SFGH cohort appear to be progressing to AIDS. Progression to AIDS over four years in asymptomatic HIV Ab+ homosexual men was well predicted by a multivariate model using five laboratory markers. Two-year progression in symptomatic men was well predicted by ARC plus one abnormal marker.

T.A.0.32 THE NATURAL HISTORY OF HIV INFECTION IN A COHORT OF HOMOSEXUAL AND BISEXUAL MEN: CLINICAL MANIFESTATIONS, 1978-1989

Lifson,A.*; Hessol,N.*; Rutherford,George W.*; Buchbinder,S.*; O'Malley,P.*; Cannon,L*; Barnhart,L.*; Harrison,J**; Doll, L**; Holmberg,S.**; Jaffe,H.**.
*Dept. of Public Health,San Francisco,CA; **AIDS Program,CDC,Atlanta,GA,USA.

Objective. To determine the relationship between clinical manifestations of HIV infection and duration of seropositivity in a cohort of homosexual and bisexual men.
Methods. We evaluated clinical manifestations of HIV infection in a cohort of 6,702 homosexual and bisexual men originally recruited from 1978 to 1980 for studies of hepatitis B. Men included in this analysis were all selected for enrollment into AIDS follow-up studies and had a well approximated date of HIV seroconversion (SC) ranging from 1977 to 1988. Using Kaplan-Meier methods, we analyzed cumulative risk of AIDS by duration of HIV infection.
Results. Of the 268 men whose SC date could be well approximated, 121 (45%) had estimated dates of seroconversion before January 1981 and had been clinically evaluated in the last 2 years (median time from SC = 100 months). Among these 121 men 63 (52%) developed AIDS, 27 (22%) AIDS-related conditions, 13 (11%) asymptomatic generalized lymphadenopathy, and 18 (15%) had no signs or symptoms on last examination. Using all 268 men, we estimated 4% of the HIV-infected men in the cohort will develop AIDS within 3 years of infection, 10% within 4 years, 15% within 5 years, 25% within 6 years, 34% within 7 years, 39% within 8 years, 43% within 9 years, and 54% within 10 years (95% confidence interval, 42-66%).
Conclusion. The risk of AIDS and other clinical manifestations of HIV infection continues to increase as duration of infection increases.

T.A.0.33 THE PROBABILITY OF PROGRESSION TO AIDS IN A COHORT OF MALE SEXUAL CONTACTS OF MEN WITH HIV DISEASE

Struthers, Cyntha *;Farewell, V.*;Coates, R.**
* Department of Health Studies, University of Waterloo, Waterloo, Ontario;
** Department of Preventive Medicine and Biostatistics, University of Toronto, Toronto, Ontario, Canada

Objective: To investigate the proportion of individiudals in a cohort of male sexual contacts of men with HIV disease who will progress to AIDS.
Methods: At recruitment 143 cohort members were seropositive and 16 seroconverted during follow-up. Information was obtained on the times of first and last sexual contact with the index case. A mixture model was fit to estimate the probability of developing AIDS in this cohort and the parameters of the incubation time distribution based on a Weibull model. Infection was assumed to occur during the period of sexual contact with the index case for individuals not seroconverting during follow-up.
Results: 35 cohort members developed AIDS while under study. The probability of developing AIDS was estimated to be at least 50% and as high as 100% with values of 73% to 100% being equally plausible estimates. In the cohort the mean incubation time was estimated to be 7.4 years and the Weibull shape parameter was estimated to be 1.96.
Conclusion: At least 50% of men with HIV disease are likely to progress to AIDS. There was no evidence of a subpopulation not susceptible to AIDS. The estimated incubation time distribution in this cohort is consistent with other estimates.

T.A.0.34 RISK OF AIDS PROGRESSION APPEARS EARLY IN HIV INFECTION

Douglas, Bruce*; Schechter, MT*; Willoughby B*; McLeod WA*; Constance P*; Weaver MS*; Montaner JS*; Craib KJP*; Le TN*; O'Shaughnessy MV**; et al.
*The Vancouver Lymphadenopathy-AIDS Study, St. Paul's Hospital and the University of British Columbia, Vancouver, BC, Canada. ** Federal Centre for AIDS, Ottawa, Ontario, Canada

Objective. To determine whether differences exist between seroconverters who subsequently did and did not develop AIDS in the Vancouver Lymphadenopathy-AIDS study with respect to laboratory variables obtained close to the time of seroconversion.
Methods. Of 118 seroconverters in our prospective study as of 11/88, we identified all 10 who later developed AIDS (denoted 'cases'). For each case, 3 AIDS-free seroconverter controls were selected at random, matched to the cases on the basis of month and year of seroconversion. Dates of seroconversion were estimated as the midpoint between the last negative (LN) and first positive (FP) antibody test result. Laboratory data were obtained from the FP visit. Comparisons were made utilizing non-parametric methods.
Results. A total of 10 cases and 30 controls were included in the analysis. The median interval duration between LN and FP was 12 months (range=4-21) for cases and 11 months (range=3-26) for controls. At FP, laboratory data were obtained a median of 27.5 months (range=16-36) prior to diagnosis for the cases. Controls were AIDS-free a median of 50 months (range=35-62) from FP to 11/88. At FP, C1q binding (median 28.0 vs 12.0; p=0.008) and IgA levels (median 345 vs 300; p=.037) were significantly elevated, and CD4 counts (median 679 vs 804; p=0.043) were significantly lower among those seroconverters who later progressed to AIDS. No differences were observed at FP with respect to hemoglobin, white blood cells, lymphocytes, IgM levels, or CD8 counts.
Conclusion. Despite limited power, we found differences early in HIV infection between those who did and did not progress to AIDS. We speculate i) either those who progressed had much longer seroconversion windows or ii) these parameters are not simply surrogates of disease progression or duration, but represent markers of susceptibility to more rapid progression to AIDS.

T.A.0.35 SIMPLIFIED BACKCALCULATIONS FOR THE AIDS EPIDEMIC.

Phillip S Rosenberg, MH Gail, RJ Biggar, JJ Goedert
(National Cancer Institute, Bethesda, Maryland, U.S.A.

OBJECTIVE: To develop simple backcalculation methods for projecting AIDS incidence and for estimating the previous incidence of HIV infection.
METHODS: We extended available methods to permit flexible models of the previous HIV infection rate. We fit these models using efficient regression techniques that were easily implemented on a personal computer.
RESULTS: Our methods provided estimates (with confidence intervals) of important features of the pattern and extent of previous HIV infections. These include: 1) the cumulative number of persons infected with HIV through 1985 and through the present; 2) The difference between average infection rates in various time periods; and 3) projections of future AIDS incidence. Because these calculations were easily performed, we could also evaluate the sensitivity of estimates to different assumptions about the natural history of AIDS and to other aspects of the analysis. These methods were applied to test cases such as persons with hemophilia and homosexual men and yielded results that were compatible with independent epidemiologic data. Using a Weibull time-to-AIDS distribution F(t)=1-exp(-.002t^2.516) derived from persons with hemophilia, we estimate that 8,100 hemophiliacs were infected prior to March 1, 1985 (standard deviation (SD) = 975). The infection rate peaked prior to 1985. Among those currently infected, we project a cumulative AIDS incidence through January 1, 1993 of 3,475 (SD=700).
CONCLUSIONS: The computational efficiency and generality of the flexible models improves the assessment of random and systematic errors. Application to other groups may provide important public health insights.

T.A.0.37 EXTRAPOLATING RECENT TRENDS TO MAKE AIDS CASE PROJECTIONS

Karon, John M.; Devine, OJ
AIDS Program, Centers for Disease Control, Atlanta, GA, USA

Objective. To evaluate extrapolation from recent trends as a procedure for making short-term projections of AIDS cases.
Methods. Trends in quarterly U.S. AIDS incidence (all cases, adjusted for estimated reporting delays) y were modeled using the Box-Cox procedure
$(y^{\lambda}-1)/\lambda$ = polynomial in time + error
The parameters were estimated by maximum likelihood.
Results. Projections of U.S. cases 5 years in the future can be very sensitive to the form of the polynomial chosen (linear or quadratic), and somewhat sensitive to the period during which the trend is modeled.

Period modeled	Reporting through	p(t)	Predicted incidence 1988	1990	1992
1/84-6/88	12/88	linear	36,500	67,000	109,000
1/84-6/88	12/88	quadratic	34,200	35,000	30,000
1/84-6/88	12/88	quadratic(log)	35,000	45,000	37,000
7/83-9/87	6/88	linear	40,000	76,000	126,000
7/83-9/87	3/88	linear	38,000	69,000	112,000

Recent estimated (adjusted) incidence continues to increase steadily.
Conclusion. Careful analysis is essential in using extrapolation methods. An arbitrary transform, such as the logarithm, should not be used. Reporting delays must be estimated carefully because extrapolations are sensitive to changes in recent data. Predictions should emphasize uncertainty, as indicated by prediction intervals, rather than a single estimate. Projections more than 2 to 3 years in the future should be used with caution.

T.A.0.39 A RISK BEHAVIOR BASED MODEL OF THE CUBIC GROWTH OF AIDS IN THE UNITED STATES

Colgate, Stirling A., Stanley, E. A., Hyman, J. M., Layne, S. P., and Qualls, C.*.
Los Alamos National Laboratory, Los Alamos, New Mexico 87545 USA, *University of New Mexico, Albuquerque, NM, USA.

Objective. To understand the spread of HIV in the United States.
Method. The cumulative number of AIDS cases in the United States has grown as the cube of time rather than exponentially. We explain this by interactions involving partner choice and sexual frequency in a risk behavior model with biased mixing. This leads to a saturation wave of infection moving from high to low risk groups. The model assumes that the distribution of people according to risk (behavior that puts one at risk of infection) decays slowly, with a significant fraction of the population engaging in high-risk activities. It assumes that people with similar risk behavior tend to interact primarily among themselves (biased mixing) rather than equally with others (homogeneous mixing). The model incorporates epidemiological data on the total AIDS cases and on the progression from initial HIV infection to AIDS.
Results. The decreasing growth rate of AIDS cases through 1988 was not due to changes in behavior, but rather it was due to the intrinsic epidemiology of the disease. The total number of persons infected with HIV in the U.S. in 1988 was approximately one million. The average duration of infection for new AIDS cases is increasing. The mean risk behavior for people being infected with HIV is decreasing. The model is consistent with a mean probability of transmission per sexual contact between 0.001 and 0.004. An increase in infectivity during the latter stages of HIV infection could increase the future growth rate of AIDS; behavior modification could reduce it,

T.A.0.36 STATISTICAL ANALYSIS OF THE STAGES OF HIV INFECTION USING A MARKOV MODEL

Longini, Jr., Ira M.*; Clark, W.S.*; Horsburgh, C.R.**; Lemp, G.F.***; Byers, R.H.**; Darrow, W.W.**; et al.
*Emory University, Atlanta, GA USA, **AIDS Program, CDC, Atlanta, GA USA, ***AIDS Office, Department of Health, San Francisco, CA USA.

Objective. Persons infected with HIV pass through a progression of stages from initially infected to death. We have estimated the waiting time distribution for each stage of infection. From these estimates, we specify the probability distributions of the AIDS incubation period, pre-HIV-antibody period, and stage-specific survival times.
Methods. The natural history of HIV was modeled by a Markov process with the following five stages: 1) infected but antibody negative; 2) antibody positive but asymptomatic; 3) pre-AIDS symptoms and/or an abnormal hematologic indicator; 4) clinical AIDS; 5) death. This five-stage model was fitted to censored data from a cohort of 558 HIV-infected individuals.
Results. From the fitted model, the estimated mean waiting times in each stage are the following: Stage 1, 2.6 months; stage 2, 52.6 months; stage 3, 62.9 months; and stage 4, 23.6 months. The 95% confidence interval (CI) on the mean pre-HIV-antibody period (waiting time in stage 1) is [2.2,3.0] months. The mean AIDS incubation period (from infection to the development of AIDS) is estimated to be 9.8 years with a 95% CI of [8.4,11.2] years. The median survival times from stages 1, 2, 3 and 4 are estimated to be 10.3, 10.1, 5.8 and 1.4 years, respectively.
Conclusion. A staged Markov model can be used to efficiently estimate important statistical descriptors of the natural history of HIV.

T.A.0.38 MODEL-BASED OPTIMIZATION OF INFECTIVITY PARAMETERS

Ahlgren David J.*; Gorny M K**; Stein A C*.
* Trinity College, Hartford, CT 06106, ** NYU Medical Center, New York, NY 10016, U.S.A.

Objectives To: 1) develop a non-linear optimization program which computes values of key epidemiologic parameters; 2) determine whether seroconversion and case rates among male homosexuals/bisexuals in San Francisco during 1978-1986 imply varying infectivity (VI) among three stages of infection (early antigen; antibody-positive; AIDS); 3) compare VI-based projections to projections that assume equal infectivity (EI) of the three stages; 4) determine if VI holds when simulated numbers of partners and contacts are changed significantly (±50%); 5) determine if VI holds for two contact models (sequential mates model and total contacts model).
Methods The optimization program minimizes the difference between simulated case rate and seroconversion fraction curves and data reported by the San Francisco Hepatitis B cohort study. Six parameters are optimized: 1) per contact transmission probabilities for each stage; 2) duration of and initial fraction in the early antigen stage; 3) delay time from seroconversion to AIDS. The cumulative fraction to AIDS vs. time since seroconversion is approximated closely by a 5th-order exponential delay.
Results Over a wide range of simulated numbers of partners and contacts, case rate and seroconversion fraction data are matched using VI. Base run optimal parameter values are: 1) contact probabilities--early antigen 0.056, antibody-positive 0.00049, AIDS 0.04; 2) initial fraction in early antigen stage 0.00248; 3) delay from seroconversion to AIDS 9.07 years; 4) duration of early antigen stage 19 weeks. With EI the (single) optimized contact probability (0.00614) is too low for the early antigen and AIDS stages, but too high for the antibody-positive stage. The case rate curve can be matched using EI, but the associated seroconversion fraction curve rises too slowly during 1978-82 and falls too slowly after 1982. VI runs predict a less severe future epidemic than EI runs. VI holds for both contact models.
Conclusion High infectivity of the first stage suggests antigen screening in high risk groups.

T.A.0.40 DRUGS, SEX & HIV: A MATHEMATICAL MODEL FOR NEW YORK CITY

Blower, Sally M.*; Courval, J.M.**; Stein, Z.A.**; May, R.M.*** and Anderson, R.M.*
*Imperial College of Science, Technology & Medicine, London University, London University, London, UK, **HIV Center for Clinical & Behavioral Studies, New York State Psychiatric Institute, Columbia University & Columbia Presbyterian Medical Center, New York, USA, ***Oxford University, Oxford, UK.

Objective To develop a mathematical model of sexual and drug behaviours in order to investigate the magnitude and time scale of the HIV epidemic in women and children in New York City.
Methods Different methods for capturing HIV transmission by intravenous drug use and heterosexual sex were explored.
Results A mathematical model was developed. The final model includes three groups of women; women who are at risk through IV drug use, women who are at risk through sexual intercourse with an IV drug user and women who are at risk due to both factors. IV drug users are assumed to either share needles with strangers in shooting galleries or to only share needles with 'shooting buddies'. Sexual and drug behaviour dynamically interact and affect both the magnitude and the time scale of the epidemic. Several scenarios will be presented in which empirical data are used to explore the model and to assess the impact of possible behaviour changes.
Conclusion The model appears to adequately capture sexual and drug behaviours and thus appears useful for exploring the HIV epidemic in women and children in New York City.

Évaluation de l'efficacité des programmes de prévention
Evaluation of Preventive Programme Effectiveness

T.A.0.41 EVALUATION OF PREVENTIVE PROGRAMME EFFECTIVENESS

Chairpersons: David Heymann (Geneva, Switzerland), Jack Wirima (Lilongwe, Malawi)
Panelists: Richard Biritwum (Geneva, Switzerland), Jean-Baptiste Brunet (Paris, France), Therese Mulandi (Nairobi, Kenya), Ron Waldman (Atlanta, USA)

Objective: To discuss various aspects of evaluation of AIDS control programmes including an overview of the place of evaluation in AIDS control programmes, approaches and problems associated with AIDS surveillance for HIV infection, feasible indicators for monitoring programme implementation and evaluating programme impact, approaches for collecting indicator information, and the place of evaluation in developing individual programme interventions.
Methods: Global experts in evaluation and implementation of disease control programmes met in Geneva to identify and select quantitative indicators which could serve as surrogates for measuring changes in HIV seroprevalence. Potential indicators of effectiveness were developed for the three main strategies of the WHO Global Programme on AIDS: decrease in sexual transmission, decrease in transmission from infected blood/blood products or skin piercing instruments, and reduction of impact on individuals, groups and societies. Methodologies were then proposed for the collection of indicator information, either through existing health information systems or from information systems developed specifically for the evaluation process.
Results: The role of evaluation in AIDS control programmes, a proposed matrix of indicators for use in evaluation, proposed approaches for collection of the indicator information and plans for validation of the indicator information and approaches were developed by the global experts and will be presented during the discussions.

Transmission du VIH dans le milieu des soins de la santé
HIV Transmission in the Health Care Setting

W.A.0.1

HEALTH-CARE WORKERS EXPOSED TO PATIENTS INFECTED WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV), UNITED STATES.

Marcus, Ruthanne* and the Cooperative Needlestick Surveillance Group. *Centers for Disease Control, Atlanta, USA.

Objective. To estimate the risk of HIV infection in health-care workers (HCWs) exposed to blood of persons infected with HIV.
Methods. HCWs from over 300 health-care institutions throughout the United States who have parenteral, mucous-membrane, or non-intact skin exposures to the blood of persons infected with HIV are tested for HIV antibody at baseline, 6 weeks, 3, 6, and 12 months after exposure. On entry epidemiologic data and confidential risk factor information are collected from each HCW.
Results. As of December 31, 1988, 1107 HCWs were tested at least 6 months after exposure. Of 982 HCWs with needlesticks (n=888) or cuts with sharp objects (n=94), 4 were positive for HIV antibody (4/982 = 0.41%; upper bound of 95% confidence interval (CI)= 0.93%). One HCW had no baseline specimen available for testing, and thus occupational acquisition could not be documented. The remaining three workers received a needlestick injury, experienced an acute retroviral syndrome, and seroconverted to HIV within 6 months postexposure. Two of the three HCWs who seroconverted were injured by a co-worker during a resuscitation procedure. Of the remaining 125 HCWs with blood contamination of mucous-membranes (n=53) or broken skin (n=72), none seroconverted (0/125=0%; upper bound of 95% CI=2.35%).
Conclusions. In this ongoing surveillance of HCWs exposed to HIV-infected blood, the risk of seroconversion following parenteral exposure has consistently remained less than 1%. Efforts must be made to prevent exposure to blood to further minimize the risk of HIV transmission to HCWs.

W.A.0.2

SURVEILLANCE UPDATE: HEALTH-CARE WORKERS WITH AIDS

Chamberland, Mary*; Conley, L.*; Bush, T.*; Jaffe, H.*.
*Centers for Disease Control (CDC), Atlanta, GA, USA

Objective. To characterize health-care workers (HCWs) with AIDS in the United States and evaluate the role of occupational transmission of HIV.
Methods. HCWs with AIDS reported to CDC who have no identified risk (NIR) are investigated by health departments using a standard protocol.
Results. As of January 16, 1989, 3,550 HCWs with AIDS had been reported. HCWs were less likely than other AIDS patients to report IV-drug use (7% vs 21%, p<0.001) and more likely to report male homosexual contact (73% vs 62%, p<0.001) or have NIR (6% vs 3%, p<0.001). One HCW with AIDS has had a documented seroconversion to HIV after a needlestick exposure to blood from an AIDS patient. Of the 203 HCWs with NIR, 125 (61%) are under investigation; 30 (15%) died, refused interview or were lost to followup; and 48 (24%) had no risk factor identified after investigation. Compared with the 6.8 million HCWs in the U.S., the 48 investigated HCWs with NIR were more likely to be black (44% vs 13%) and less likely to be women (29% vs 77%). They comprised 8 physicians, 1 dentist, 5 nurses, 1 paramedic, 11 aides/orderlies, 2 respiratory therapists, 5 clinical lab technicians, 9 maintenance workers, 2 morticians, and 4 others with no patient contact. Twenty (42%) of the 48 HCWs reported needlestick and/or mucous membrane or non-intact skin exposures to blood or other body fluids; in none was the HIV status of the patient known.
Conclusion. Most HCWs have an identified risk for HIV infection; the others probably represent a mix of persons with unreported behavioral risk factors or unrecognized occupational exposures.

W.A.0.3

PREVALENCE OF HIV INFECTION AMONG PERSONS EMPLOYED IN MEDICINE AND HEALTH OCCUPATIONS

Cowan David and the Walter Reed Retrovirus Research Group
Walter Reed Army Institute of Research, Washington, DC USA

Objective To examine the association between employment in Medicine and Health (MH) occupations and infection with HIV.
Methods Test results for HIV-Ab have been received on 545,114 US Army Reserve Component personnel. These individuals spend about 10% of their days in a military environment, and are employed in civilian occupations.
Results When examined by Dept of Labor occupational categories, those employed in the medicine and health (MH) field had a prevalence of 2.46 (per 1000), versus 1.51 for those not so employed. The 2397 white, black, and Hispanic male and female physicians and dentists were all HIV-Ab negative. The prevalence among white females (n=4291) in MH jobs was 0.23, compared to 0.23 for those in other occupations. The prevalence for black females in MH occupations (n=1714) was 1.23, and 1.84 in other occupations. Among white and black single males, the prevalence was significantly higher for registered nurses (RN), medical technicians (MT), and not otherwise specified medical occupations (NOS). The prevalence among single white males was 7.50, and the prevalence ratio (PR and 95% confidence interval), versus those not employed in MH occupations, was 7.26 (3.71, 14.21). In single black males the prevalence was 31.60, with a PR of 4.76 (2.90, 7.82). Prevalence was not significantly higher for 4569 ever-married black, white, and Hispanic males employed in RN, MT, or NOS jobs; nor among 2738 ever- and never-married black, white, and Hispanic males in all other MH fields.
Conclusions The higher prevalence associated with employment in MH fields is largely restricted to single white and black males employed in the RN, MT, or NOS areas. The absolute prevalence is much higher among single black males, but the PR is higher for single white males. These patterns of HIV infection do not support the hypothesis of an occupational risk of infection that is detectable by prevalence surveys.

W.A.0.4

ADHERENCE TO UNIVERSAL PRECAUTIONS BY HCWs IN AN INNER-CITY EMERGENCY DEPARTMENT WITH HIGH HIV-1 PREVALENCE AMONG PATIENTS

Kelen, Gabor; DiGiovanna T; Kalainov D; Bisson L; Scott C.
Johns Hopkins University School of Medicine, Baltimore, Maryland, USA.

Objective: To assess adherence to "Universal Precautions" (UP) among health care workers (HCWs) in an emergency department (ED) with high prevalence (6.0%) of HIV-1 among its patient population.
Methods: We prospectively observed 129 HCWs performing 1274 interventions on 151 consecutive patients requiring rapid interventions. Institution-wide and departmental instructional sessions on UP were held for HCWs throughout the year prior to the initiation of the study. Interventions were classified as major (42.5%) or minor (57.4%) depending on the potential for exposure.
Results: Overall adherence was adequate during 16.5% of major interventions and 64.8% of minor interventions (p<.05). During minor interventions, adherence was the same for trauma presentations (62.9%) and non-trauma presentations (67.0%) (p>.05). However, in the presence of profuse bleeding, adherence during minor interventions declined to 19.7% in traumatic presentations (p<.05) and 0.0% in non-trauma presentations (p <.05). During major procedures, adherence was 34.0% with traumatic presentations and 0.8% with non-trauma presentations (p <.05). The overall adherence rate for HCWs was: Residents 58%; Attendings 38%; Consultants 43%; Nursing staff 44%; Paramedics 8%; X-ray technicians 14%; and Housekeeping 91%. When precautions were inadequate, surgical masks were used least (22.4%), followed by eye protection (45.0%), gowns (49.6%) and gloves (73.7%). A questionnaire administered following the study period revealed that the most common reasons given for not adhering to UP was lack of time to put on protective materials (47%), and interference in performance of procedures (33%).
Conclusion: HCWs in this setting are not taking adequate precautions. Other strategies for implementing Universal Precautions need to be developed.

W.A.0.5

NOSOCOMIAL OUTBREAK OF HIV INFECTION IN ELISTA, USSR

V.V. Pokrovsky, E.U. Eramova
Central Institute of Epidemiology, Moscow, USSR

A total of 41 out of 2504 children and 8 of 115 mothers of children who had been admitted to hospital in Elista Town (Kalmykia Republic, USSR) during the period from May until December 1988 were found HIV antibody positive by ELISA and Western Blot testing. No other HIV infection was identified among 20,000 inhabitants of Elista including 948 hospital workers and 1032 members of families of infected persons. Only 1 of 9 sexual partners of the 8 infected women was HIV positive. This man lived and was possibly infected in Africa in 1981. A child of his HIV seropositive wife died in hospital in May 1988 and is thought to have been the first infant in a chain of HIV infection. Other seropositive children are assumed to have been infected during overlapping admissions to the hospital. The virus appears to have been transmitted in hospital by use of one syringe into which blood was aspirated between intravenous injections. Four mothers for whom no risk factors were identified appear to have become HIV infected through blood of their children. It is hypothesized that the virus was transmitted from bleeding oral lesions in in children treated with heavy doses of antibiotic to bleeding fissures on mothers breasts during breast feeding. Results of the final analysis of the investigation will be reported.

Transmission hétérosexuelle
Heterosexual Transmission

W.A.O.6 HETEROSEXUAL TRANSMISSION

Chairpersons: Frank Plummer (Nairobi, Kenya), Martin Schechter (Vancouver, Canada)
Panelists: Marie Laga (Antwerp, Belgium), Nzilambi Nzila (Zaire, Africa)
Nancy Padian (San Francisco, USA)

Although a clear picture is emerging of the epidemiology of HIV transmission in gay men, our understanding of heterosexual transmission is not so consistent or well developed. The prevention of heterosexual HIV spread is clearly one of the critical global challenges in this epidemic. This symposium will attempt to review what is known and what is not known about heterosexual transmission and to generate consensus on some outstanding issues. Topics to be covered include the efficiency of male-to-female and female-to-male contact and current estimates of the transmission probabilities of various forms of contact. Several 'cofactors' operating at the level of the genital tract or at the systemic level have been implicated as influencing HIV transmission. These can act by increasing the infectivity of the index partner and/or the susceptibility of the secondary partner. In this regard, the role of other sexually transmitted diseases including genital ulcer disease and chlamydial cervicitis, the role of oral contraceptives, the role of circumcision, and the role of stage of HIV infection and viremia in the transmitter will be discussed among others. The scientific study of HIV transmission has been hindered by several methodologic problems which will be reviewed. These include difficulties in ascertaining the direction of transmission in couples where both are seropositive at entry into a study, obtaining reliable and valid measurements of sexual exposures (types of sexual practices, frequency of exposure, use of condoms, etc), and controlling for the confounding effects of other exposures. Solutions to these problems will enhance our ability to characterize the role of already identified and yet to be identified factors which increase the risk of HIV transmission. Knowledge of these factors will be critical for predicting the likelihood of future heterosexual epidemics and more importantly, for identifying potential intervention strategies aimed at the control of HIV transmission.

STATEWIDE HIV-1 SEROLOGIC SURVEY OF NEWBORNS WITH RESULTANT CHANGES IN SCREENING AND DELIVERY SYSTEM POLICY

Altman, R.; Grant, Christine M.; Brandon, D.; Shahied, S.; Rappaport, E.; Costa, S.; et al.
New Jersey State Department of Health, Trenton, New Jersey, U.S.A.

Objective. To determine the prevalence of HIV-1 in New Jersey mothers and infants by blind testing for anti HIV-1 antibodies in newborns.
Methods. Filter paper blots of blood from all newborn infants in New Jersey are tested for metabolic diseases. These specimens were also tested for anti HIV-1 by EIA tests, with repeatedly EIA positive specimens tested by immunoblot tests during July-September 1988.
Results. 144, or 0.49% of 29,309 newborns tested positive for anti HIV-1. Extrapolating to annual births, 516 and 660 HIV-1 infected women are giving birth to infants annually in New Jersey a state of 7.4 million population. Rates were particularly high, 1.58% and 1.27% in the two counties with the highest AIDS case rates, and most AIDS cases related to intravenous drug abuse.
Conclusion. Estimating that about 1/3-1/2 of infants born of HIV-1 infected mothers will be infected themselves, about 200-300 HIV-1 infected infants are being born annually in New Jersey. In view of the criticality of early medical intervention, a policy of nonblinded neonatal HIV-1 testing of all infants appears indicated by these findings, as is a specialized system of counseling and health care for HIV-1 positive infants and mothers. Extrapolating this same rate of infection to all women of childbearing age in New Jersey would suggest that there are 8000-9000 infected women in New Jersey, the state with the second highest AIDS incidence in the United States. This is lower than previous estimates.

W.A.0.8

HIV INFECTION IN ADOLESCENT CHILDBEARING WOMEN

Novick, Lloyd*; Glebatis, D.*; Stricof, R.* and Berns, D.**

*New York State Department of Health, Albany, New York, USA, **Wadsworth Center for Laboratories and Research, New York State Department of Health, Albany, New York, USA.

Objective. To determine age-specific rates and trends of HIV infection in adolescent childbearing women in New York State.
Methods. An ongoing blind newborn HIV seroprevalence study tested 276,606 newborns during a 12-month period.
Results. The childbearing women infection rate was 0.66 percent (New York City = 1.3%; other New York State = .16%). Rates were lower among women less than 20 years (.43%) compared to 20-29 years (.67%) and 30-39 years (.69%). Rates for adolescent childbearing women are: 15 years (0.8%); 16 years (.30%); 17 years (.32%); 18 years (.39%); 19 years (.62%). Rates for adolescents were 0.89% for Hispanics, 0.59% for Blacks and 0.1% for Whites. Rates of adolescents in New York City were 3 1/2 times higher than for the rest of New York State. Prevalence increased with each year of age.
Conclusion. The survey documents a large number of HIV infected adolescents (117) and provides information on the extent of the problem not available from AIDS case surveillance.

W.A.0.9

MEASUREMENT OF HIV SEROPREVALENCE IN CHILDBEARING WOMEN IN LONDON.

Tedder Richard S.*; Briggs,M*; Parra,N.*; Ades,A.**; Helm,M***; Peckham,C.**

* University College and Middlesex School of Medicine, Ridinghouse Street, London, U.K.
** Institute of Child Health, Guildford Street, London, U.K.
*** The Hospital for Sick Children,Great Ormond Street, London, U.K.

Objective To asses the efficacy of a method of large scale anonymous screening for evidence of HIV 1 infection in childbearing women using a cost-effective modification of a sensitive assay.
Methods Neonatal whole blood dried on filter- paper discs, taken for phenylketonuria assay (PKU), were used as described by Dr R.Hoff et al.. The blood was eluted from the discs providing a 100µl sample of an approximate 1 : 60 dilution of serum. This was tested for anti-HIV 1 using a modification of the Fujirebio gelatin particle agglutination assay (Serodia HIV). Reactive samples were titrated in the modified Serodia-HIV assay and tested in a Western Blot assay capable of using small volumes. The data generated were compared with the prevalence data collated by the Communicable Diseases Surveillance Centre PHLS..
Results Testing the eluted samples with modified Serodia HIV and Western Blot gave a sensitivity equivalent to that obtained when testing neat sera in current ELISAs (non-recombinant). In the first six months, up to Jan.1989, 46,600 PKU samples have been assayed. Of 10 repeatably reactive eluates 9 were unequivocally confirmed as anti-HIV 1 positive by Western Blot. This is a prevalence rate of 0.02%.
Conclusions The method we describe is accurate and inexpensive (total cost £0.125 per sample). It is an extremely simple way of ensuring total anonymity in testing and is suitable for widespread use.

HIV INFECTION IN PREGNANT WOMEN AND PERINATAL TRANSMISSION IN SWEDEN

Bohlin, Ann-Britt**; Anzén, B***; Arneborn, M*; Böttiger, M*; Forsgren, M****; Lidman, K***; Lindgren, S**; von Sydow, M****.
*Dept of Epidemiol National Bacteriol Lab, **Depts of Pediatr, Obstetr and Psychiatr, Huddinge Hospital, ***Depts of Obstetr and Infect Dis, Danderyds Hospital, ****Central Microbiol Lab, Stockholm, Sweden.

Screening for HIV in pregnant women is an important instrument to follow heterosexual transmission, and it gives valuable epidemiological information. In Sept 1 1987 a national HIV screening program was started in pregnant women in Sweden, and the acceptance rate is high.
Method: Pregnant women are offered an HIV test at their first visit to the antenatal care unit. A central reporting system has been set up, and the number of tests and HIV positive women are reported.The children are followed up.
Results: As of Nov 30 1988, 17 out of 130 508 tests were HIV positive(0.013%). 12/17 women were heterosexually infected. Eight women elected abortion, nine continued pregnancy. Apart from the screening there are another 22 children in Sweden born to HIV positive mothers. 2/27mothers have died of AIDS, 7 have HIV-related symptoms, 0-68 months after delivery. The median age of the children is 33 (0-78) months. Eight children (7 >15 months) are known to be HIV infected, 3 of whom have got AIDS (1 died). Another 14 children are more than 15 months old, clinically well and HIV negative (not infected). Eight children are less than 15 months old and clinically well (indeterminate).
Conclusion: HIV screening in pregnancy gives the families the possibility to elect abortion and to avoid future pregnancies. It is also an important part of the national HIV surveillance. The rate of infection in pregnant women in Sweden was found to be 0.013% and the perinatal transmission rate was 33%.

W.A.0.11

HIV SCREENING PROGRAM AT A LOS ANGELES PRENATAL/FAMILY PLANNING CENTER

Fehrs, Laura; Hill, D.; Kerndt, P.; Rose, T.; Henneman C.
Los Angeles County Department of Health Service, Los Angeles, USA

Objective: To evaluate HIV seroprevalence and the efficacy of a selective voluntary HIV testing program at a public prenatal (PN) and family planning (FP) clinic.
Methods: Between March and September 1988, blood specimens remaining from routine testing of 3,000 women, who were mostly Hispanic (87%) and of recent arrival to the U.S. (median 5 yrs), were tested for HIV antibody after all identifiers were removed.
Results: Four women (0.13%) tested positive (3/1801 Pn and 1/1167 FP). Three reported no risk factors; one reported a history of syphilis in the past year. Voluntary HIV testing was offered to women who reported having risk factors for HIV infection on interview. Only 14% (96/685) of clients selectively offered testing, 28% (14/50) of clients determined by investigators to be at highest risk of infection, 27% (16/59) of women who judged that they had had a chance of being exposed to HIV, and none of 4 women positive by blinded testing chose voluntary testing. Black women were 4.2 times more likely than Hispanic or White women to choose voluntary testing (p 0.001); the effect of race on acceptance of testing was greatest for lower risk women.
Conclusion: While few women in this clinic population are infected with HIV, higher risk women were not effectively persuaded to be tested through this program of voluntary HIV testing for selected persons. The design of voluntary testing programs should consider strategies to increase acceptance of testing, especially by persons at high risk, as well as local seroprevalence.

W.A.0.12

NATIONAL SURVEYS OF HIV SEROPREVALENCE IN WOMEN DELIVERING LIVE CHILDREN IN THE UNITED STATES.

Peppaioanou,Marguerite*; George,R*; Hannon,H**; Hoff,R***; Willoughby,A****; Novello,A****; State Health Departments; et. al.*,**,***
*AIDS Program, CID, CDC, Atlanta GA; **CEHIC, CDC, Atlanta, GA; ***Massachusetts Department of Health, Boston, MA; ****NICHD, Bethesda, MD, U.S.A.

Objective. To obtain unbiased estimates of HIV prevalence in childbearing women by geographic area and demographic subgroup, and to monitor trends of infection over time.
Methods. In statewide surveys, neonatal blood specimens collected on filter paper for neonatal screening programs are tested for maternal antibody to HIV by EIA; repeatedly reactive specimens are confirmed by Western blot. Laboratories participate in CDC's Program of Quality Assurance for HIV Seropositivity of Dried Blood Spots. Information on month and year of infant birth, and in most states county of mother's residence and hospital location, and mother's age- and/or racial/ethnic-group is linked to test results. Information identifying individuals or hospitals is not retained.
Results. Thus far, 18 of 44 participating States and territories in 4 regions have reported provisional statewide seroprevalence rates from complete or partially complete surveys: Northeast 0.03% - 0.66%; South 0.09% - 0.46%; North Central 0.06% - 0.09%, and Mountain 0.03% - 0.04%.
Conclusion. The prevalence of HIV in women delivering live children varies by state and region. The unbiased estimates of prevalence obtained in this defined population at risk are important for developing and directing education/prevention programs, monitoring heterosexual transmission, validating completeness of AIDS case reporting, and for projecting the number of women and children with AIDS needing health care.

ARE AIDS CASES AMONG HOMOSEXUAL MALES LEVELING?

Berkelman, Ruth*; Karon, J.*; Thomas, P.**; Kerndt, P.***; Rutherford, G.****; Stehr-Green J.*
*Centers for Disease Control, Atlanta; **New York City (NYC) Dept of Hlth, ***Los Angeles (LA) Co. Health Dept, ****San Francisco (SF) Dept PH, USA

Objective. To analyse trends in reported cases of AIDS among homosexual and bisexual males in major metropolitan areas of the U.S.
Methods. We analyzed AIDS cases in NYC, SF, and LA and the rest of the U.S. among homosexuals and bisexuals (HB) without intravenous drug use (IVDU) from 1982 through 1988 by 6-month intervals, by race, by date of diagnosis, adjusting for reporting delay; and by date of report.
Results. The rate of increase for reported AIDS cases among HB has slowed in the U.S., earlier in NY, SF, and NYC (by 1987) than the rest of the U.S; the slowing has occurred for both whites and other races in most areas.

Percent change from previous 6 mo.-period in AIDS among HB (no IVDU) by date of diagnosis, adjusted for reporting delay

	1985(1)	(2)	1986(1)	(2)	1987(1)	(2)	1988 (1)
New York City	+32	+4	+26	+17	+2	-4	+11
Los Angeles	+66	+28	+32	+14	+14	0	-6
San Francisco	+30	+16	+28	+24	+10	-2	+8
U.S. (other)	+55	+40	+28	+29	+34	+11	+10

When analyzed by date of report, leveling is less apparent.
Conclusion. Reported AIDS cases among HB males are leveling across the U.S., noted earlier in selected metropolitan areas. Underreporting, differences in medical practices, early saturation of infection, and behavioral changes should each be evaluated as contributing factors.

W.A.0.14

HETEROSEXUAL AIDS IN THE PROVINCE OF QUEBEC

Robert S. Remis, Lucie Bédard, Robert W.H. Palmer
Bureau régional des maladies infectieuses,
Montréal, Québec, Canada

Objective: To characterize the epidemiology of AIDS among heterosexual persons resident in the province of Québec, Canada.
Methods: Surveillance for AIDS was carried out since 1983; reports were evaluated using the WHO epidemiologic case criteria. Further data was collected for AIDS cases with heterosexual contact indicated as the source.
Results: From 1979 to January 15, 1989, 743 cases of AIDS were reported in Québec; 78 (10.5%) were among women and 30 (4.0%) among children, compared to 2.8% and 0.6% respectively for the rest of Canada. One-hundred-and-forty-six (19.6%) cases were due to heterosexual contact, for a rate of 21.9 cases per million population versus 1.7 for the rest of Canada. Seventy-nine percent of the excess in Québec can be explained by the markedly increased risk of AIDS among heterosexual immigrants from Pattern II countries, mostly Haiti: the incidence rate of AIDS in 1988 among non-homosexual Haitians in Québec was 710 as compared to 4.2 per million population for other non-homosexual Québecers, for a relative rate of 170. The rate of AIDS among heterosexual partners of high-risk persons was also higher in Québec: of the 37 cases reported in this group, 25 (68%) were related to sexual contact with persons from Pattern II countries, 13 having had exposure in Québec and 12 in the endemic regions themselves.
Conclusion: The rate of AIDS among heterosexuals in Québec is the highest in Canada. Most of the excess can be explained by the high rate of AIDS among heterosexual persons from Pattern II countries and among other heterosexuals with sexual partners from Pattern II countries.

W.A.0.15

SURVEILLANCE OF HETEROSEXUALLY ACQUIRED AIDS, U.S.A.

Chamberland, Mary*; Conley, L.*; Buehler, J.*.
Centers for Disease Control, Atlanta, GA, USA

Objective. To monitor temporal and demographic trends in the United States for adults with heterosexually acquired (HA)-AIDS.
Methods. HA-AIDS cases reported to CDC include heterosexual persons (exclusive of IV-drug users or hemophilics) who (1) report sexual contact (SC) with a person with or at increased risk for HIV infection or (2) were born in areas with high rates of HA-HIV infection, such as Haiti or Africa.
Results. As of January 16, 1989, 3654 HA-AIDS cases were reported: 2390 (65%) in persons with SC and 1264 (35%) in persons from endemic countries (98% of whom were Haitian). Although the proportion of HA-AIDS cases has remained relatively stable (ranging from 5.2% of all adults reported in 1983 to 4.8% in 1988), the composition of the group has changed: Haitians/Africans accounted for 79% of the 107 HA cases reported in 1983, but only 25% of the 1543 cases in 1988. Excluding homosexual men, SC cases have increased from 0.5% of men with AIDS reported in 1983 to 3.9% in 1988 ($p<0.001$) and from 14.8% of women to 25.6% ($p<0.001$). Most SC cases continue to be women (75%) and blacks or Hispanics (70%). Among SC cases, women are significantly younger than men (34 years vs 40 years, mean age). Both men and women reported SC with IV-drug users with equal frequency (71%). Men who reported SC were less likely than women (18% vs 49%) to reside in New York or New Jersy, which account for 63% of AIDS cases in heterosexual IV-drug users.
Conclusion. HA-AIDS remains largely focused in demographically distinct population groups. The proportion attributable to SC is increasing.

W.A.0.16

IMPACT OF THE HIV EPIDEMIC ON MORTALITY TRENDS IN MEN 25-44 YEARS OF AGE, UNITED STATES

Buehler, James; Berkelman R., Devine O.; Chevarley F.
Centers for Disease Control, Atlanta, Georgia & Hyattsville, Maryland, USA

Objective. To identify causes of death that are increasing among young adult men in association with the HIV epidemic in the United States.
Methods. We analyzed national death records for 1980-1986 (underlying and multiple causes), compared cause-specific mortality trends in states with high versus low AIDS incidence, and calculated excess deaths in 1986 based on 1983 rates (the nadir of total mortality for men 25-44 years of age).
Results. Following decades of decline, national mortality rates for men 25-44 years of age increased from 212.1 in 1983 to 233.9 deaths/100,000 in 1986. By 1986, conditions in the AIDS surveillance definition represented 9% of deaths, with mortality rates ranging from 45.8 in five states with the highest AIDS incidence to 6.2 deaths/100,000 in 21 states with the lowest AIDS incidence. Similarly, rates for deaths due to infections not in the AIDS definition (including pneumonia, septicemia, and pulmonary tuberculosis), blood disorders, drug abuse, and unspecified causes increased more rapidly in states with high versus low incidence AIDS. This pattern was not observed for other cause groups, including cancers with a previously suggested link to HIV (oropharyngeal, anal/rectal, Hodgkins lymphoma). Of the 8,654 excess deaths in 1986 among causes that increased from 1983, 72% were attributed to conditions in the AIDS definition, 8% to other infections, 7% to drug abuse, and 6% to unspecified causes.
Conclusion. The HIV epidemic has led to an increase in diverse causes of death and to a reversal in mortality trends for young men.

W.A.0.17

NATIONAL SURVEILLANCE OF PERINATALLY-ACQUIRED AIDS, USA.

Margaret J. Oxtoby, M. Rogers, T. Bush, R. Berkelman.
Centers for Disease Control, Atlanta, Georgia, USA.

Objectives. To examine temporal trends in perinatal AIDS (PA) cases.
Methods. Analysis of the 1046 PA cases reported to CDC from 1982-88.

Results:PA cases reported 1985-88	1985	1986	1987	1988
Number of cases newly reported in yr	105	160	256	449
% of cases meeting only 9/1987 defn	0%	0%	16%	44%
Number (%) of cases with age dx ≥5yrs	9(8%)	15(9%)	18(7%)	54(12%)
Median age at AIDS dx: overall	10 mo	12 mo	9 mo	14 mo
for cases meeting pre-1987 defn	10 mo	12 mo	8 mo	9 mo
for cases meeting 1987 defn only	—	—	18 mo	20 mo
Disease: % with P.carinii pneumonia	52%	46%	45%	31%
Median age at dx for PCP cases	6 mo	6 mo	5 mo	6 mo
Median age at dx for other cases	20 mo	18 mo	15 mo	19 mo
Residence: % from NY, NJ, or Florida	74%	64%	57%	60%
Maternal risk: % with hx IV drug use	58%	56%	53%	52%
Race/ethnicity: % Black or Hispanic	89%	87%	84%	81%

50% of cases were in boys, 50% in girls; there was no sex difference in age at diagnosis, disease presentation, or survival time after diagnosis.
Conclusion. PA yearly incidence is increasing; offspring of drug users remain the group most severely affected. More school-age children are being newly dx'd with PA, but since many newly infected children are born each year, the median age at dx has been fairly constant. Broadening of the case definition may have most affect on reportability of older children, who are less likely to present with opportunistic infections such as PCP.

W.A.0.18

THE RELATIVE IMPORTANCE OF AIDS AS A CAUSE OF DEATH IN PEDIATRIC AND YOUNG ADULT POPULATIONS IN THE U.S.1980-1987.

Kilbourne, Barbara W.; Rogers, M.F.; Bush, T.J.
Centers for Disease Control (CDC), Atlanta, Georgia, U.S.A.

Objective. To assess the impact of AIDS relative to other leading causes of death in persons less than 25 years of age in the U.S.
Methods. Yearly AIDS mortality rates computed from CDC national surveillance data were compared with rates for the leading causes of death obtained from national vital statistics data for the age groups <1 year, 1-4 years, 5-14 years, and 15-24 years for 1980-1986 and estimated for 1987.
Results. For <1 year olds, the mortality rate (per 100,000 live births) for AIDS rose from 0.028 in 1980 to 1.3 in 1986 and 2.02 in 1987. By 1987, AIDS is estimated to have been the 30th leading cause of death for this age group. Among 1-4 year olds, the rate (per 100,000) of AIDS mortality was 0.015 in 1981 and rose to 0.445 in 1986, when AIDS became the 10th leading cause of death in this age group, and 0.767 in 1987 when it is estimated to have been the 9th leading cause of death. In the 5-14 year age group the rate rose progressively to 0.155 in 1987 when AIDS is estimated to have been the 15th leading cause of death. Yearly rates for the 15-24 year age group were 1.02 in 1986 and 1.33 in 1987, substantially higher than for younger age groups, except for the <1 year olds. Among 15-24 year olds, AIDS was the 10th leading cause of death as early as 1984 and is estimated to have been the 6th leading cause in 1987.
Conclusion. Rates of AIDS mortality are increasing in the pediatric and young adult populations in the U.S. AIDS is now one of the ten leading causes of death among 1-4 year olds and 15-24 year olds in the U.S.

Partner Notification

W.A.0.19

EXPERIENCE OF PARTNER NOTIFICATION AMONG HIV INFECTED HETEROSEXUALS IN BRUSSELS

Arendt, V.; Hermans, Ph.; Schoumacher, M.; Clumeck, Nathan. Division of Infectious Diseases, St Pierre University Hospital, Brussels, Belgium.

During a 2 year period, 105 out of 289 heterosexual HIV seropositive patients were enrolled in a partner notification study, consisting in notification, counseling and testing (by Elisa and Western blot) of sexual partners. Fourty-five out of 105 (43%) were eligible. Reasons for withdrawing from the study were : refusal of cooperating (47%), partners out of Belgium (37%), miscellaneous (16%). The 45 index cases allowed notification of 92 heterosexual partners. The index persons were : 25 males, 20 females; mean age was 34,8y (range: 19-66); 35 Caucasians, 10 black Africans. Sexual partners were stratified according to their matrimonial status or relationship to index case as married (31%), regular sexual partner (18%), occasional partner (51%). Only 9 partners were using condoms (10%) during their sexual intercourse with index cases. Overall HIV seroprevalence was 36/92 (39%). Among the various groups of partners, seroprevalence was respectively : spouses (57%), regular partners (35%), occasional partners (30%). All partners received information about risk reduction procedures and health services in case of seropositivity.

This study suggests that partner notification is efficient as a technique aimed to inform, counsel and test heterosexual partners who ignore their exposure to HIV. Further studies are needed to assess the impact of partner notification on avoidance of risk behaviour and on reduction of further transmission of HIV, which is the first goal of the technique.

W.A.0.21

RESULTS AND BENEFIT-COST ANALYSIS OF PROVIDER-ASSISTED HIV PARTNER NOTIFICATION AND REFERRAL Spencer, N; Raevsky, C. Wolf, F; STD/AIDS Section, Colorado Department of Health, Denver, Colorado USA.

Objective: Evaluate results, benefits and costs of provider-assisted partner notification and referral to prevent HIV infection.

Methods: HIV Ab positives were interviewed by Disease Intervention Specialists (DIS) to notify sex/needle share partners of exposure. Partners were offered risk reduction counseling and HIV Ab testing. Program costs for personnel, travel and supplies were calculated as were local medical costs for the estimated number of AIDS cases prevented through this intervention.

Assumptions: HIV infection would have remained unrecongnized in newly identified cases and each would have transmitted to one susceptible in the course of a lifetime; 50% of HIV infected individuals develop AIDS.

Results: 172 HIV Ab positives were interviewed. They identified 289 local unsafe sex/needle share partners and suspects, of which they chose to self-refer 25%. 209 (72%) were located. 25 (18%) located partners were previously tested positive, 15 (10%) were previously tested negative. 111 (73%) had not yet been tested and 105 (95%) of these accepted new counseling and 72 (65%) also accepted new testing. 11 new positives were identified. Program costs during 1988 totalled $27,050 and program benefits totalled $194,700. Benefit-cost ratio was 7.2.

Conculsion: Provider assisted HIV partner notification and referral has high partner acceptance of new testing (65%), identifies previously undetected infections in potential transmitters, (15%) and has a high benefit-cost ratio (7.2).

W.A.0.23

ASSESSMENT OF THE DEVELOPMENT AND IMPLEMENTATION OF STATE AIDS/HIV PARTER NOTIFICATION PROGRAMS: FIVE CASE STUDIES

Lorraine M. Fishback*, J. William Flynt**, James Focht, Lela Baughman, and Cynthia Morgan; *Office of the Assistant Secretary for Health, Public Health Service, Washington, D.C. and ** Macro Systems, Inc., Silver Spring, Maryland.

Objective. To gather information on the characteristics, preliminary results, and apparent benefits of existing partner notification programs.

Methods. A case study methodology was used to collect detailed information on the design and operation of five state/local programs for notifying, educating, and counseling the sex and needle-sharing partners of individuals testing antibody-positive for HIV. The sites selected--Colorado, Florida, Virginia, San Francisco, and Seattle-King County, Washington--represent a range of approaches that, in combination, have much to teach others embarking on establishment ofpartner notification programs.

Results. The study confirmed that current State and local realities determine both the mix of methodologies being used in HIV prevention/education programs and also the particular approach being taken to notify partners. Cost-effectiveness balanced by a concern for public health were also major factors.

Conclusion. A generic planning model for initiating partner notification activities was developed from the comparative analysis of the five sites. The model highlights various steps in three phases of planning--epidemiology assessment, policy development, and program implementation. This model will be exhibited.

W.A.0.20

PARTNER ACCEPTABILITY OF HEALTH DEPARTMENT NOTIFICATION OF HIV EXPOSURE, SOUTH CAROLINA

Jones, Jeffrey L.*; Wykoff, RF**; Gamble, WB, Jr.**; Hollis, SL**; Longshore, ST**; Gunn, RA*. *Division of Field Services Centers for Disease Control, Atlanta, GA, USA. **South Carolina Department of Health and Environmental Control, Columbia and Greenwood, SC, USA.

Objective. To determine partners' acceptability of notification by the health department of their exposure to human immunodeficiency virus (HIV).

Methods. An anonymous questionnaire administered to sex or IV drug contacts 2 to 24 months after the health department notified them of exposure to HIV.

Results. Available partners (79 persons) of HIV positive persons in one health district (6 counties) completed the questionnaire. Of the 79, 61(77%) were male and 18(23%) were female; 57(72%) black, 22(28%) white; 60(76%) homo/bisexual, 15(19%) heterosexual, and 4(5%) IV drug user. Ages ranged from 16 to 71 years (median 28 yrs). Only 9(11%), thought they had been exposed to HIV before health department notification. After notification and testing, 20(25%) were found to be HIV antibody positive. Of the 20, 14(70%) were male and 6(30%) were female. When asked if they felt the health department did the right thing in telling them about exposure, 68(86%) responded yes, 0(0%) no, and 11(14%) not sure. When asked if the health department should keep telling people when they have been exposed to HIV, 70(89%) responded yes, 4(5%) no, and 5(6%) not sure. When asked if being told they were exposed to HIV was helpful, 64(81%) responded yes, 3(4%) no, and 11(14%) not sure. Responses were similar for homo/bisexual men and heterosexuals, males and females, whites and blacks, and HIV positives and negatives.

Conclusion. Health department notification is highly acceptable to health department clients exposed to HIV in this rural South Carolina district.

W.A.0.22

PARTNER NOTIFICATION FOR HIV PREVENTION: CURRENT STATE POLICY IN THE UNITED STATES

Toomey, Kathleen*; Cahill, K*; Cates W*.
*Centers for Disease Control, Atlanta, GA, U.S.A.

Objective. Partner notification (PN), used for many years in STD control programs, has been broadened to include the notification of sex and needle-sharing partners of individuals infected with HIV. PN encompasses two distinct strategies, patient referral and provider referral; all PN programs are based upon some combination of these two strategies.

Methods. In the AIDS prevention projects supported by CDC, states have been required to implement procedures for confidential PN. State programs were canvased to determine the extent of their current PN activities.

Results. All 50 states, Puerto Rico, the Virgin Islands, and the District of Columbia currently counsel HIV infected clients about the need to inform sex and needle sharing partners of their risk for infection (patient referral) and offer provider referral upon request by clients. Fifteen states have PN programs that encourage provider referral for all clients. Data available from 13 states demonstrate seroprevalence among partners of individuals with HIV infection ranges from <1% to 16.4%. Infection among female sex partners of bisexual men ranges from 0-7%; infection among sex partners of IV drug users ranges from <1% to 15%.

Conclusions. Partner notification is being applied increasingly in HIV prevention programs in the US to identify individuals at risk for infection. Evaluations to measure the efficacy of these programs among different ethic/racial groups and for individuals with different risk behaviors are currently being developed by CDC.

W.A.0.24

COMBATTING AIDS WITH CONTACT TRACING

The Swedish Study Group on Contact Tracing for HIV Infection*

In the Swedish effort to combat HIV infection and AIDS, contact tracing is considered as a fundamental tool. It is seen as an integrated part of the total medical and psychological care for the patient. It is assumed to be an important element in the reduction of the spread of the disease, due to the behavioural change effect of counselling and to the finding of hitherto unknown infectives. It has also been suggested to be much more economical than screening programmes for finding infected individuals.

A collaborative study, including most of the centres involved in the care of HIV infected patients, has been initiated, with the scope of describing the effects of contact tracing, as well on the individual as on the spread of the disease. The study consists of a retrospective analysis of contact tracing results and a prospective study of behavioural changes in and positive/negative effects for the individual patients. Possible epidemiological inferences from contact tracing statistics are also studied.

Thus far, the following preliminary estimates of the results of contact tracing for HIV infection in Sweden have been made: on the average, each index patient gives rise to 1.5 identifiable contacts; most of these are tested and 80% have known test results. One third of these tests are positive. About 40% of positive individuals identified in this way are previously unknown to the health care system.

* presented by Dr. J. Giesecke, Dept. of Environmental Health & Disease Control, Karolinska Hospital, Stockholm, Sweden (coordinator of the project). The project has been financed by a grant from the Swedish insurance company AFA.

Test de dépistage du VIH/Questions en matière de politiques et de programmes
HIV Testing/Policy and Programme Issues

W.A.0.25 MANDATORY PREMARITAL HIV ANTIBODY TESTING: A TWELVE MONTH EXPERIENCE

Kelly, C. and Turnock, B. Illinois Department of Public Health, Springfield, Illinois, USA.

Objective. To evaluate the effectiveness of mandatory premarital HIV antibody testing as an AIDS intervention method. Methods. Effective January 1, 1988, all marriage licenses applicants in Illinois are required by state law to prove that they have been tested for the presence of HIV antibodies and that test results have been communicated to both parties to the proposed marriage. The age, race, sex and history of risk behavior of all persons with Western blot confirmed positive results are reported to the Illinois Department of Public Health although individual identifiers are not. The number of marriage licenses issued is reported to the IDPH Registry of Vital Statistics. Results. Twenty-six of 155,458 marriage license applicants were found to be positive (seroprevalence = .02%). Of these, 62% reported a history of risk behavior. This is the same rate as has been observed for voluntary blood donors in Illinois. At an estimated per-capita cost of $35, the cost of premarital testing is estimated at $5.4 million annually, or $217,641 per seropositive individual identified, compared with $770 per seropositive individual identified through the state's Counseling and Testing program. The number of marriage licenses issued in Illinois decreased by 22% when compared with the previous twelve month period. Conclusions. Mandatory premarital HIV antibody testing in Illinois has identified few seropositive individuals at an enormous cost. Counseling and testing and partner notification programs targeting persons at risk of infection are more cost-effective than widespread mandatory screening of low prevalence populations.

W.A.0.26 HIV ANTIBODY TESTING AMONG ADULTS IN THE UNITED STATES

Hardy, Ann M. and Dawson, D., National Center for Health Statistics, Hyattsville, MD, United States.

Objective. To determine awareness, levels, and circumstances of HIV antibody (ab) testing in the United States (U.S.) adult population.
Methods. Data collected during May-October, 1988 from 21,168 adults with the AIDS supplement to the National Health Interview Survey (NHIS) were examined. Results were weighted to provide national estimates.
Results. Three-quarters of U.S. adults had heard of the HIV ab test. Groups less aware of testing included blacks (66%), Hispanics (66%), those with little or no self-assessed knowledge about AIDS (56%), and those not completing high school (55%). Overall, 17% of adults reported ever taking the HIV ab test, with percent tested varying among population groups:

Group:	Males	Females	Whites	Blacks	Hispanics	Single	Increased risk
% Tested:	20%	13%	17%	14%	14%	23%	28%

Of those tested, 71% had been tested due to blood donation, 12% as part of another activity requiring testing (e.g., military physical), and 18% were tested voluntarily. In all groups, blood donation was the most common reason for testing. Those tested voluntarily were more likely to be single, to report knowing alot about AIDS, and report being at increased risk for HIV/AIDS than those tested for other reasons.
Conclusions. While awareness of HIV ab testing is generally high, it is relatively low in some important groups (e.g., minorities). One in 6 U.S. adults has been tested, primarily through blood donation. While many tested voluntarily appear to be in groups targeted for testing, a large proportion of these groups have not yet been tested.

W.A.0.27 HIV ANTIBODY STATUS AND BEHAVIOR CHANGE IN TWO COHORTS OF GAY MEN IN SAN FRANCISCO: THE SAN FRANCISCO MEN'S HEALTH STUDY (SFMHS) AND THE AIDS BEHAVIORAL RESEARCH PROJECT (ABRP)

Coates, Thomas J.; Ekstrand, M; Kegeles, SM; Stall, RD.
Center for AIDS Prevention Studies, UC San Francisco, CA, USA

Objective. To analyze the impact of knowledge of HIV antobody status on behavior change and distress in two cohorts of gay men in San Francisco.
Methods. The ABRP (N=415), a convenience sample surveyed annually since 1984, allowed us to examine the relationship between knowledge of serostatus and behavior change among individuals who chose to be tested and to receive their results using community resources. The SFMHS (N=519), recruited in 1984 using probability sampling, were tested but had the choice of learning their serostatus. This study allowed us to determine the relationship of serostatus knowledge, independent of serostatus, and behavior change.
Results. The majority of men in both studies had learned their serostatus by 1987 (ABRP= 56.7%; SFMHS=64.5%). After adjusting for other predictors (AIDS loss, AIDS prodromal symptoms, depression, age, anxiety), knowledge of positive serostatus was associated with significantly lower rates of unprotected anal intercourse insertive (ABRP adjusted odds ratio= .51, $p < .05$; SFMHS adjusted odds ratio= .50, $p < .05$), but not with lower rates of unprotected anal intercourse receptive or multiple partner sex. Men who were less depressed, reported fewer prodromal symptoms. Younger men were also likely to continue to practice unprotected anal intercourse receptive.
Conclusions. Knowledge of positive serostatus can lead to behavior change. These results may be enhanced when testing is confidential or anonymous and assurances of non-discrimination are legislated.

W.A.0.28 TARGETING AIDS PREVENTION TOWARDS HIV-INFECTED PERSONS. Do Prevention/Treatment Programs reduce transmission and improve the quality of life?

D P Francis*,
Gorman M*, Fenstersheib M**, Esposito A** Padian N**, Henke-Quinn W** , et al.*Centers for Disease Control, Berkeley, CA, *Rand Corporation, Santa Monica, CA **Santa Clara County Health Department, San Jose, CA, **Long Beach Department of Public Health, Long Beach, CA **University of California, San Francisco, CA

Objective. We report here the first attempt to field and evaluate a medical, behavioral and psychosocial follow-up program for HIV-positive persons.
Methods. In March 1988, the California Department of Health Services established two pilot AIDS Prevention and Follow-up Centers (APFC), one in Northern California (San Jose) and one in Southern California (Long Beach). Entry into the program, which provides medical/immunological evaluation together with behavioral and psychosocial evaluation and intervention at four month intervals, is open to any HIV-positive person. In addition to services provided at the clinic, personally assigned case managers make outside referrals to a variety of medical and social support programs. The knowledge, psychological adjustment and behavior of clients are measured through standardized questionnaires administered at entry into the program and at each follow-up visit. These include questions about high-risk behavior including sexual activity, needle/syringe sharing activity, drug/alcohol use, knowledge of serologic status of partners and the use of protective devices or materials. The emotional status of clients is measured using Beck's depression and hopelessness scales. The overall effect of the program is measured by comparing the various educational, behavioral and adjustment parameters at entry to those at various intervals after entry. In addition, the effect of a five week education course has been measured by comparing the knowledge, behaviors and emotional adjustment of those who have completed the course to those who have not.
Results. To date 459 persons have been entered into the program 62 have had two visits and 4 three visits. Most (95%) of these are men, most report homosexual activity as their risk behavior for infection, and most (69%) are white.
Conclusion. 1. It has been suggested that both public and personal benefits accrue by establishing long-term follow-up programs for HIV-positive persons which provide medical, behavioral, psychosocial and case management services (Francis, et. al., JAMA, in press). 2. Although second visit follow-up is incomplete, success has been demonstrated by high recruitment and follow-up visits.

W.A.0.29 HIV EPIDEMIOLOGY IN SWEDEN

Böttiger, Margareta
National Bacteriological Laboratory, Stockholm, Sweden

Objective. To follow the HIV epidemic in Sweden and evaluate the impact of preventive measures.
Methods. Establishing and evaluation of report systems and screening programs for surveillance of HIV-infected persons and other sexually transmitted and blood-borne diseases. Main surveillance systems comprise: Reports of HIV-positive persons, Reports of tests and categories of persons tested from laboratories, Surveillance of pregnant women, persons from high endemic areas, STD clinics, centers for IV drug users, blood donors, etc. From 1984 to 1989, 1 million tests (excluding blood donors) were reported (population 8.4 million). Over 20% of the sexually active population may be tested.
Results. Up to 1989, 2,009 persons were reported as HIV-positive, half of them were homosexual men,one quarter IV drug users, close to 200 infected by blood products and the rest mainly heterosexually infected. Five perinatally infected children were seen. Current trends are increasing homosexual transmission, continuous but low spread among IV drug users, and that 1/10,000 of new blood donors and 1/10,000 of pregnant women are seropositive.
Conclusion. Even in a country with comparatively low prevalence of HIV and high ambition to combat AIDS/HIV, HIV continues to disseminate. Efforts to prevent and analyse the course of events must continue.

W.A.0.30 RISK FACTORS AND HIV SEROPREVALENCE IN SCREENING U.S. IMMIGRATION APPLICANTS - 1988

Sankary, Timothy, AIDS Prevention Center, San Francisco, California, USA.

Objective. To assess the demographics, risk factors and seroprevalence of HIV infection in U.S. immigration applicants.
Methods. We surveyed and conducted physical exams on 3266 consecutive applicants for U.S. immigration in 1988 who were required to have HIV antibody and syphilis tests as part of their application. (72% male, 28% female with a mean age of 29.4 +/- 9.8 years, median age 27, mode 22; 88% hispanic, 4.5% asian, and 6.4% other non-white; country of origin was Mexico 56%, El Salvador 15%, Guatemala 6%, Phillipines 4%, Nicaragua 3%, Peru 3%, Other 14%).
Results. The sample was predominantly heterosexual (99%) with 36% married, 3% divorced, 42% unattached singles and 20% attached to one partner. None were hemophiliacs, 2% had received transfusions, 0.1% had abused IV drugs. Last sexual intercourse was a mean of 225 +/-904 days, mean 15, mode 1 day. Approximately 69% had sex in the last 60 days and 75% had sex in the last 90 days. Only 8.6% had used a condom during the last sex. Of those, 19% had unprotected intercourse in the last 60 days. The men had a mean number of 5.9 female partners in the last 5 years and 8.9 in the last 10 years, while the women had a mean number of 1.6 men in the last 5 yrs and 2.1 men in the last 10 yrs. 12% reported having high-risk partners (all prostitutes, 62% local, 38% foreign) and 20% had them in the last 60 days while only 37% used condoms. Approximately 1.7% had serologic evidence of syphilis (RPR+,FTA+) and an additional 1% gave a history of syphilis in the past, while 1.5% reported past gonorrhea. The RPR test had 6/61 (10%) false positives when confirmed by FTA. The ELISA HIV antibody test (Abbott) showed 33 reactive specimens for which 10/33 (30%) were confirmed as positive by Western Blot (Dupont) for an overall seropositive rate of 3 per 1000. The 10 men seropositives: 1 gay, 1 bisexual, 1 heterosexual IV drug user, 1 heterosexual West African, and 6 heterosexual men with no known risk factors.
Conclusion. Applicants for U.S. immigration represent a low-risk population. Mass screening tends to ignore the large percentage of recent sexual contacts within the seroconversion window. The common use of prostitutes without condoms in this population indicates a need for better health education.

Côntrole de l'épidémie de VIH
Monitoring the HIV Epidemic

Th.A.O.1 MONITORING THE HIV EPIDEMIC

Chairpersons: James Chin (Geneva, Switzerland), Timothy J. Dondero (Atlanta, USA)
Panelists: O. Noel Gill (London, United Kingdom), Steve Lwanga (Geneva, Switzerland), Lloyd Novick (Albany, USA)

Increasingly, countries are conducting or planning HIV serologic surveys to help health officials assess and monitor the changing patterns and spread of the epidemic. Survey approaches vary but sentinel surveillance, in which levels and trends of HIV infection are tracked in selected accessible subpopulations, is emerging as a practical approach to monitor the various patterns of HIV spread in the population at large. In the roundtable, a panel of five specialists in HIV serosurveillance will discuss issues related to HIV surveys and reflect on the experience to date. The topics will include 1) the needs for and uses of serosurveillance; 2) surveys in sentinel populations - choice and implications of the populations selected; advantages, disadvantages, and legal/ethical aspects of anonymous unlinked (blinded) surveys compared with surveys in groups who volunteer; interpretation of data from and biases in sentinel populations; and 3) surveys using probability samples of the population - advantages, disadvantages, and feasibility. Time will be reserved for audience participation in follow up discussions.

Modélisation mathématique
Mathematical Modelling

Th.A.0.2 MATHEMATICAL MODELLING

Chairpersons: Roy M. Anderson (London, United Kingdom), Ron Brookmeyer (Baltimore, USA)
Panelists: Carlos Castillo-Chavez (Ithaca, USA), James Curran (Atlanta, USA), John Koran (Atlanta, USA), G. Medley (London, United Kingdom), Andrew Moss (San Francisco, USA)

The five papers in this session examine various aspects of the use of mathematical and statistical methods in the epidemiological study of HIV and AIDS. The topics include the use of statistical methods to make short term (one to two years) projections of the future incidence of AIDS, in back calculation of the number of infecteds underlying a given AIDS cases notification pattern and to estimate the incubation period of the disease in different age classes and at risk groups. Mathematical methods are described to investigate the transmission dynamics of HIV, its potential demographic impact in developing countries and the importance of heterogeneity in sexual behaviour to the pattern of the epidemic. The session will also include a discussion of the estimation of epidemiological parameters, the interpretation of trends in incidence of infections and disease and data needs.

Transmission périnatale
Perinatal Transmission

Th.A.0.3

VERTICAL TRANSMISSION OF HIV INFECTION-EUROPEAN COLLABORATIVE STUDY UPDATE

Catherine Peckham, A.E. Ades, M.L. Newell (coordinators) for the European Collaborative Study. Institute of Child Health, London. Collaborating centres include: Padua, Berlin, Edinburgh, Madrid, Valencia, Amsterdam, Stockholm, and Genoa.

Objective To determine the rates of transmission of HIV infection from mother to child.
Method Children born to mothers known to be HIV positive at or before the time of delivery are enrolled in the study, and examined at three-monthly intervals with laboratory testing by standard protocol. Infection is defined as the clinical presence of AIDS/ARC, the presence of virus or antigen or the persistence of antibody beyond the age of 18 months. Children who have lost antibody and in whom virus or antigen has not been detected are presumed not to be infected. Transmission rates are based on 118 children who have been followed up for over 18 months.
Results 315 children had been enrolled by 20 January 1989. The majority(85%) of these children were born to IVDA mothers. Drug withdrawal symptoms were present in 25% of the babies. Birthweight was related to mother's use of drugs but not to HIV infection status. 13 children have developed AIDS/ARC, 5 of whom have died, a further 27 children showed significant signs or symptoms suggestive of HIV infection. A total of 42 children are known to be infected, 31% of whom developed AIDS/ARC, all within the first nine months of life. Bearing in mind the relative insensitivity of virus and antigen tests, a minimum estimate of vertical transmission rate is 22.9% (95% confidence interval 15.3%-30.5%).

Th.A.0.4

HIV ANTIBODY NEGATIVE CHILDREN WITH POSITIVE VIROLOGY: OBSERVATIONS FROM THE EUROPEAN COLLABORATIVE STUDY

Marie-Louise Newell, C.S. Peckham, A.E. Ades for the European Collaborative Study. Institute of Child Health, London. Collaborating centres include Padua, Berlin, Edinburgh, Madrid, Valencia, Amsterdam and Genoa.

Objective Interpretation of antibody in children born to HIV infected mothers.
Method Children born to mothers known to be HIV positive at or before the time of delivery are enrolled in the study and followed up at three-monthly intervals with a medical and laboratory examination using a standard protocol. Testing for antibody is by ELISA confirmed by Western Blot, detection of virus is by reverse transcriptase activity with antigen capture.
Results Of the 315 children enrolled in the study by 20 January 1989, 149 have lost antibody. The median age at antibody loss among those who lost antibody was 10.2 months. After an average of 14.4 months follow-up none have become and remained positive subsequently. Among the 97 children over 18 months who were antibody negative, 6 must be regarded as infected following at least one virus isolation or positive antigen test. The median age of antibody loss for these children was 14.1 months. These 6 children have been followed up for an average of 8.6 months (range 0 to 25.5) since losing antibody, and all of them were clinically well and immunologically normal at the time of their last visit. Details of these children will be presented and implications of this finding for assessing transmission rates and for follow-up of such children will be discussed.

Th.A.0.5

BREAST FEEDING AND HIV-1 TRANSMISSION

Hira,Subhash*;Mangrola,U.*;Mwale,C.*;Mwansa,N.*;Chintu,C.*; Perine,P.** et al.
*University Teaching Hospital, Lusaka, Zambia,**Uniformed Services University of Health Sciences, Bethesda, USA.

Objective. To assess the risk of HIV-1 transmission by breast feeding.
Methods. At University Teaching Hospital in Lusaka, Zambia, two groups of children were prospectively followed for 2 years:
Group I: 641 women who were HIV-1 (p24 and antibodies) negative at labour were retested after 1 year to determine the incidence of HIV-1. Their mean age was 24.5 years s.d. +/- 7.5. Sixteen (2.5%) women acquired HIV-1 heterosexually during the year. 8 breast-fed children who were born to incident cases prior to acquisition of HIV-1 were followed upto the age of 2 years. Group II: 30 breast-fed children born to HIV-1 (p24 and antibodies) negative mothers whose husbands were HIV-1 seropositive at time of labour. All children in both groups were breast-fed for 15-18 months. ELISA (Dupont) for p24, Recombigen (Cambridge BioScience) for HIV-1 antibodies, and Immunofluorescent assay for confirmation were used.
Results. Of 8 children born of incident women, 2 children seroconverted at 20 and 22 months of age (Group I). No risk factors other than breast-milk were identified. Mothers of both children had developed PGL. Remaining 6 children were negative and healthy upto 2 years of age and their mothers were asymptomatic. Group II: Of 30 women, 3 (10.0%) seroconverted at 8, 10 and 12 months of followup. Child of the later mother was p24 positive at 15 months.
Conclusion. There is evidence of breast-milk transmission from incident cases.

Th.A.0.6

HIGH PERINATAL HIV RATES WITH PREMATURITY OR LOW ANTI-GP120

James J Goedert*, H Mendez**, A Willoughby*, SH Landesman**. * National Institutes of Health, Bethesda MD 20892; ** SUNY Health Science Center, Brooklyn NY 11203, U.S.A.

Objective. To evaluate cofactors and markers of perinatal HIV transmission.
Methods. The 64 offspring of HIV-infected women who were enrolled during pregnancy in a prospective cohort study were evaluated to a median age 12 months (34% >15 months) with serial T-cell subsets, HIV-Ab (EIA), p24-Ab and gp120-Ab (RIA) during pregnancy, postpartum and infancy. HIV infection rates and time-dependent covariate analyses were evaluated both from birth date and estimated conception date.
Results. AIDS was diagnosed in 7, P2A without lab requirement in 3, and asymptomatic HIV-Ab >15 months in 1 at ages 3-15 (median 5) months. Thus 11 of 64 babies were infected, yielding HIV rates since birth of 17/100 person-years (py), cumulative 36%±.7%. The 14 premature (gestation ≤37 weeks) babies were at higher risk than full-terms (≥38 weeks, 42 vs 11/100py p=.02). Transmission rate was not associated with predelivery maternal T cells, EIA, or p24-Ab levels (p≥.51) but was elevated in the lowest gp120-Ab tercile (31/100py p=.06). Full-term babies were only infected by mothers in the lowest gp120-Ab tercile (38/100py), but there was no added risk for premature babies. Adjusted for prematurity, HIV infection was better distinguished by lower infant T4 (<18% or 2200/ul, p≤.01) or T4/T8 (<1.5, p=.003) than by levels of EIA, p24-Ab, or gp120-Ab (p=.16-.74). It was also distinguished by low maternal T4/T8 at the most recent visit (p=.02).
Conclusion. Although based on few cases, premature babies may be at high HIV risk, with some protection for full-term babies of mothers with gp120-Ab.

Th.A.0.7

EARLY PREDICTORS AND RATE OF PERINATAL HIV DISEASE.

Thomas Pauline A., and The New York City (NYC) Perinatal HIV Transmission Collaborative Study Group. NYC, USA.

Objective. To evaluate rate of transmission and early predictors of perinatal HIV disease.
Methods. Pregnant women at risk for HIV are enrolled at 5 NYC hospitals. Evaluation of infants born HIV+ and HIV- includes history, physical, T-cells, IgG, HIV serology, HIV genome detection (PCR), p24 antigen, and viral culture every 2-6 months, for three years.
Results. Of 94 babies born to 92 HIV+ mothers, 14 developed CDC class P2 HIV illness (HIV ill) including 11 (33%) of those born ≥15 mos ago. Twenty two seroreverted (SR) by 11 months on average (including all those ≥15 mos and 5 with symptoms but no laboratory evidence of HIV class P2A). HIV-ill were compared with both 13 well SR and with 53 infants born HIV-:

	HIV ill	Well SR	Born HIV-
Mother:HIV-illness prebirth	9/13	1/13*	0/53*
PCR positive at birth	5/10	0/ 5	0/ 6
At 4 months: mean T4	1314	2596*	3260*
mean IgG	1771	681*	607*
Lymphadenopathy	8/10	4/13	5/42*
Hepatomegaly	5/ 9	3/13	1/47*
Thrush	5/ 9	1/13	8/53*

*p<.05. P-values refer to HIV-ill vs SR or HIV-ill vs born HIV-. Also SR were different from infants born HIV- only in hepatomegaly rate (p<.05).
Conclusions. Transmission rate of perinatal HIV illness is at least 33%. Maternal HIV symptoms predict infant HIV disease. In the infant, immunologic parameters are better early predictors than physical findings.

Th.A.0.8

MATERNAL RISK FACTORS FOR PERINATAL TRANSMISSION OF HUMAN IMMUNODEFICIENCY VIRUS-1 (HIV-1).

Hutto, C., Scott, Gwendolyn, Mitchell, C. and Parks, W. University of Miami, Department of Pediatrics, Miami, FL, U.S.A.

Objective: To examine the association between maternal factors and HIV-1 transmission to infants with perinatal HIV-1 infections.
Methods: Demographic, immunologic and virologic variables were analyzed for HIV-1 seropositive mothers of 17 HIV-1 infected and 39 uninfected Haitian infants enrolled in a population-based prospective study of perinatal HIV-1 infection and clinical outcome. Logistic and multiple regression analysis were used to identify maternal risk factors associated with infant infection.
Results: For the 2 groups of infants, the following maternal variables were analyzed for association with HIV-1 infection in their infants: maternal age, type of delivery (vaginal vs. C-section), number of children, breastfeeding history, maternal hemoglobin, total WBC, absolute lymphocytes, CD4, CD8, and CD11 positive lymphocytes, IgG, IgM, IgA and HIV-1 antibody titer. Of these, an association was found for maternal age and IgA. The relative risk estimate for women older than 30 years was significantly elevated (p<0.02) and an elevated maternal IgA had an odds ratio of 17 (200mg/dl difference), p<0.04.
Conclusion: In this study, maternal age and serum IgA were related to clinical outcome of infants born to HIV-1 seropositive mothers. Although the biological basis of their association is not clear, the role of age and IgA as risk factors should be evaluated in other prospective studies.

Rôle du dépistage et du counseling dans la prévention du SIDA
The Role of HIV Testing and Counselling in AIDS Prevention

Th.A.O.9 THE ROLE OF HIV TESTING AND COUNSELING IN AIDS PREVENTION

Chairpersons: Hunter H. Handsfield (Seattle, USA), Sirkka-Lisa Valle (Helsinki, Finland)
Panelists: Stephen Bowen (Atlanta, USA), Edward W. Hook, III (Baltimore, USA), Gloria Ornelas-Hall (Mexico, Mexico)

In the four years since reliable laboratory tests for HIV infection became available, their utility in AIDS control programs has become increasingly apparent. Nonetheless, numerous questions remain concerning the application and efficacy of serologic testing for HIV prevention and control. What data are available on the efficacy of testing and counseling for disease control? What additional research is indicated, and what are the pitfalls in designing studies? What are the diffential influences of testing versus counseling on behavior change? Are there differences in the efficacy of counseling and testing between different risk group categories, or from one country to another? Are there circumstances in which either pre-test counseling or post-test counseling may be curtailed or deleted? Is there a role for anonymous testing and counseling, or for home-based self-testing? These and related questions will be addressed by a panel of public health authorities from North America, Europe, and Latin America.

Quéstions de Méthodologie
Methodologic Issues

Th.A.0.10 HIV SCREENING IN LOW PREVALENCE POPULATIONS: SHORT TERM SEROCONVERSION EXPERIENCE OF EIA+/WB- INDIVIDUALS

Pres. Robert: McNeil, J.; Burke, D. and The Walter Reed Retrovirus Research Group. Walter Reed Army Institute of Research, Washington, DC, USA.

Objective. To determine if an ELISA positive/WB- test result is a significant predictor of seroconversion after short-term followup in a low prevalence population of US young adults.
Methods. From October 1985 to November 1988, 248,761 soldiers on active duty in the US Army were tested for HIV-Ab on two or more occasions. The average interval between tests was 8 months. Individuals who were EIA- or EIA+/WB- were considered HIV-Ab negative. HIV seropositivity was defined as duplicate EIA+ plus WB+ on two separate specimens.
Results. During the study period, 119 persons seroconverted (0.048%).

		Followup Serostatus		
		Pos.	Neg.	
Initial ELISA	Pos.	13	1,135	1,148
	Neg.	106	247,507	247,613
		119	248,642	248,761

Sensitivity = 10.92%
Pos. predictive value = 1.13%
Specificity = 99.54%
Neg. predictive value = 99.96%
Pos. likelihood ratio = 23.93 ([13/119] / [1135/248,642])
Neg. likelihood ratio = 0.89 ([106/119] / [247,507/248,642])

Conclusion. EIA positivity that is not associated with confirmatory WB reactivity significantly increases the relative likelihood of confirmed seropositivity after a short followup. However, in a low risk population, EIA positivity alone did not strongly predict subsequent seropositivity for specific individuals (less than 1/88 in this case). Demographic, geographic, and behavioral correlates of infection risk could increase the predictive power of EIA+ test results in low prevalence populations.

Th.A.0.11 INCIDENCE OF PEDIATRIC AIDS IN THE UNITED STATES: PREDICTIONS FROM SEROPREVALENCE DATA

Gwinn, Marta*, Rogers M*, Berkleman R*, Willoughby A**, Novello A**, Pappaioanou M*. *AIDS Program, CID, CDC, Atlanta, GA, **NICHD, Bethesda, MD, USA

Objective. To predict incidence of AIDS in the first year of life for infants born in 1988, and compare with reported cases among infants born in 1986 and 1987.
Methods. The population-based Survey in Childbearing Women provided an estimate of the prevalence of HIV infection among United States women delivering live infants in 1988. The proportion of infants born to HIV-infected mothers who develop AIDS by 12 months of age was estimated from ongoing cohort studies. Infants born in 1986 and 1987 who were known to have developed AIDS in the first year of life were those reported to CDC.
Results. In 1988, at least 1 per 1000 childbearing women had antibody to HIV. If between 5% and 10% of their infants develop AIDS in the first year of life, approximately 225 to 450 cases of AIDS in infants under 12 months of age would be expected to occur in the 1988 birth cohort. As of January 1, 1989, 137 children born in 1986 and 130 born in 1987 had been reported to CDC with AIDS diagnosed by age 12 months.
Conclusion. A lag in case reporting complicates the comparison between numbers of AIDS cases occurring among infants born in 1987 and cases predicted among those born in 1988. However, seroprevalence data suggest that more AIDS cases will occur in the 1988 birth cohort than have been reported from previous cohorts to date.

Th.A.0.12 RELATIONSHIP BETWEEN CUMULATIVE INCIDENCE OF AIDS AND PREVALENCE OF HIV IN WOMEN OF REPRODUCTIVE AGE IN THE UNITED STATES.

Pappaioanou, Marguerite*; Buehler, J*; Gwinn, M*; Karon, J*; Wright, A**; Novello, A**. *AIDS Program, CDC, Atlanta, GA; **NICHD, Bethesda, MD, U.S.A.

Objective. To determine whether the cumulative incidence of AIDS reflects the observed prevalence of HIV in women of reproductive age in the U.S.
Method. State-specific HIV prevalence rates (per 100,000 population at risk) in women of reproductive age in 1988 were estimated by results from blinded HIV seroprevalence surveys in childbearing women. The corresponding cumulative AIDS incidence rates in women aged 15-44 years, for 1981-1988, were based on AIDS patients reported to CDC. The Pearson product moment correlation coefficient with 99% confidence intervals, and ratio of HIV prevalence to cumulative incidence of AIDS were calculated. Using simple linear regression, cumulative incidence was regressed on prevalence.
Results. Analysis of preliminary results from 12 states showed cumulative AIDS incidence to be correlated with HIV prevalence (r = 0.88; 95% C.I.: 0.67, 0.95). 75.9% of the variation in cumulative incidence was explained by prevalence of HIV. The ratio of HIV prevalence to cumulative incidence varied by state, ranging in value from 9 to 43 (median = 20.71).
Conclusion. Our results suggest that despite the lengthy incubation period of AIDS, cumulative AIDS incidence rates currently reflect the HIV epidemic in women of reproductive age. The ratio of cumulative incidence to estimated HIV prevalence varied by state. Higher ratios may indicate incomplete AIDS reporting, a higher prevalence of HIV infection in childbearing women than in women of reproductive age, or an increase in HIV transmission.

Th.A.0.13 EVALUATING THE FEASIBILITY OF THE NATIONAL HOUSEHOLD SEROPREVALENCE SURVEY (NHSS)

Ezzati T.; McQuillan Geraldine; Massey J. National Center for Health Statistics, Hyattsville MD, U.S.A.

Objective. To describe the major potential sources of error for the NHSS the possible impact of these errors on HIV prevalence rates, and possible methods to assess and enhance the quality of the survey estimates.
Methods and Results. Major potential sources of error for NHSS include coverage bias, nonresponse bias, misclassification bias and the validity of the serologic test. A sensitivity analysis of the potential impact of differential nonresponse revealed that high nonresponse among high risk persons will have the greatest impact on nonresponse bias. Nonresponse bias could potentially result in an estimated prevalence of from one-third to one and one-quarter of the true prevalence. The coverage bias associated with the under reporting of IV drug users was determined to be less than 10% on the total prevalence of HIV. Misclassification bias does not affect the estimated prevalence for the total population, but does affect the prevalence estimates classified by risk status. The relative bias in the prevalence estimates for high risk persons due to misclassification could be as large as 35%. For low risk persons the prevalence could be as much as 28 times the true prevalence, therefore separate estimates by risk group are not planned for this survey. Risk data will be collected for adjustment of nonresponse bias. To minimize nonresponse bias, a nonrespondent follow up study is proposed. Other methods to evaluate and reduce the bias include a randomized response, geographic stratification, and hepatitis B testing.

Th.A.0.14 APPLICATION OF LOT QUALITY ASSURANCE (LQA) SAMPLING TO HIV AND AIDS SENTINEL SURVEILLANCE

Lwanga, S.[1*], Chin, J.[2*], Mann, J.[3*]
*World Health Organization, Geneva, Switzerland.

Objective: To describe possible applications of Lot Quality Assurance Sampling (LQA) techniques in sentinel surveillance.
Methods: LQA and standard sampling techniques are described with their benefits and limitations in sentinel surveillance for HIV and AIDS.
Results: When sentinel surveillance centres are established to act as a "barometer" for HIV infection and AIDS in a target population group, it may not be necessary to screen very large numbers of people. LQA sampling techniques, with origins in industrial studies, may be used in this case. The strategy in industry is to classify a batch of items as not likely to have a level of defective items higher than a particular value, with a given probability. A similar strategy can be applied to a sentinel surveillance system for HIV infection and AIDS in which, unless a pre-determined percentage of people are found positive among a randomly selected group, one can conclude that the level of infection among the target group is not above a particular level.
Conclusion: Using LQA sampling techniques in HIV and AIDS surveillance greatly reduces the minimum sample sizes which would be needed to determine that a target group is not likely to have an HIV prevalence rate above a pr-determined critical value. In areas with very low levels of HIV infection LQA techniques would be more efficient than methods which would aim at estimating the prevalence levels in the target groups.

Th.A.0.15 Methodological Considerations for Assessing the Impact of Condom, Spermicide and Oral Contraceptive Use on HIV Transmission

Sanie, Ruby T.; Kleinbaum D.; Eaker E.; Lee N. and Peterson H., Centers for Disease Control, Atlanta, Georgia, U.S.A.

Numerous investigations have been initiated or are being planned to investigate the likelihood of HIV transmission in heterosexual couples who consistently and correctly use condoms, spermicides, and/or oral contraceptives. To rigorously study this critical question, a complex composite of methodological concerns must be addressed including: 1) appropriate selection of the study population, 2) knowledge of HIV status at entry of all study participants, 3) the reliability of measures to assess sexual activity and contraceptive use, 4) the temporal correlation of seroconversion with contraceptive use, and 5) the ability to accurately measure and account for other covariates of HIV transmission including the infectivity of some participants and the receptivity to infection of others. If these methodological concerns are not adequately addressed, observed associations between contraceptive use and HIV transmission may be misleading. Most sources of systematic error in such studies will bias toward observations of 1) a reduced efficacy of condoms in preventing HIV transmission and 2) a positive association between oral contraceptives and HIV transmission. To maximize the likelihood of identifying real associations, such biases need to be minimized in design strategiegies and, if not eliminated, considered when study results are interpreted.

Transmission sexuelle du VIH (partie 3)
Sexual Transmission of HIV (Part 3)

Th.A.0.16 EVALUATION OF THE ROLE OF NITRITE INHALENTS IN HIV TRANSMISSION: CONFOUNDING OR EFFECT MODIFICATION?

Seage III, George R.*; Mayer, KH**; Horsburgh, CR***; Holmberg, S.***; Lamb, GA*.
*Boston Dept. Health, **Fenway Community Health Center, Boston MA, ***Centers for Disease Control, Atlanta, GA., USA

OBJECTIVE. To evaluate the potential role of nitrite use in enhancing the risk associated with HIV transmission in a cohort of 329 gay men.
METHODS. Symptomatic (n=54) and asymptomatic (n=275) male homosexuals and their male sexual partners were enrolled from May, 1985 until May, 1988. All participants were interviewed and had HIV serologies. In logistic regression, nitrite use remained significantly associated with HIV infection (OR=2.3, 95% CI=1.2-4.6). Additional nitrite information was obtained including type, frequency, duration, "peak" usage, places of purchase, and use during specific sexual activities. Of the original 329 participants, 275 (84%) were interviewed at their second visit (6 months).
RESULTS. 80% of the respondents had a history of nitrite use. 74% used ampules, 74% used unlabeled bottles, and 38% used labeled bottles. Use of nitrites was significantly associated with HIV infection (OR=2.7, 95% CI:1.4-5.3). Those who practiced receptive anal intercourse (RA) while simultaneously using nitrites were significantly more likely to be infected (OR=1.8, 95% CI=1.1-3.1) than individuals who practiced receptive anal intercourse without simultaneous use of nitrites after adjusting for the number of sexual partners and exposures.
CONCLUSION. Simultaneous nitrite use may significantly increase the likelihood of receptive anal transmission of HIV.

Th.A.0.18 SYPHILIS IS STRONGLY ASSOCIATED WITH HIV INFECTION IN BALTIMORE STD CLINIC PATIENTS INDEPENDENT OF RISK GROUP

Cannon, Robert*; Quinn, T* **; Rompalo, A* ***; Glasser, D***; Groseclose, S***; Hook, E* ***; *Johns Hopkins University; **NIAID; ***Baltimore City Health Department, Baltimore, Maryland, USA;

Objective. To evaluate the association between serological tests for syphilis (STS) and HIV infection in Baltimore STD clinic patients.
Methods. During April and May 1988 all STD clinic patients were asked to complete a self-administered questionnaire to elicit selected demographic and HIV risk factor information. Serum samples were tested by HIV-1 EIA (confirmed with WB) and STS (RPR [confirmed by FTA]). The association of STS with HIV was determined after stratifying on gender and risk behavior using logistic regression to control for questionnaire responses significantly associated with HIV infection in univariate analyses.
Results. 175 (5.6%) of the 3150 men and 60 (3.5%) of the 1712 women tested were HIV positive (HIV +); 199 (6.3%) men and 118 (6.9%) women were STS +.

HIV +/# Tested(% Positive)

	RISK	STS +	STS -	OR(95% CI)	P
Men	Homosexual	19/33(57.6)	23/122(18.8)	3.6(1.3,7.4)	0.009
	Het. IVDU	10/22(45.4)	35/227(15.4)	4.6(1.8,11.4)	0.001
	Het. non-IVDU	30/144(20.8)	58/2602(2.2)	8.7(4.9,15.5)	<0.001
Women	Het. IVDU	7/11(63.6)	10/64(15.6)	9.4(2.3,38.4)	0.002
	Het. non-IVDU	11/107(10.3)	32/1530(2.1)	5.4(2.6,11.1)	<0.001

Conclusion. STS positivity is strongly associated with HIV infection in Baltimore STD clinic patients irrespective of age, gender, number of sex partners in the month preceding testing, IV drug use and male homosexual behavior.

Th.A.0.20 HETEROSEXUAL TRANSMISSION OF HIV: A EUROPEAN STUDY. II: FEMALE-TO-MALE TRANSMISSION.

De Vincenzi, Isabelle*; Ancelle-Park R.* for the European Community Study Group. * WHO Collaborating Centre on AIDS, Paris, France

OBJECTIVE: To determine risk factors of female-to-male HIV transmission.
METHODS: Between March 87 and October 88, 65 couples were recruited from 6 European countries. Data for HIV(+) females (Index Case-IC) and their heterosexual partners (HP) are collected every 6 months. HP presenting risks for HIV infection other than sexual contacts with the IC were excluded. The cross-sectional analysis of data from the first interview is presented.
RESULTS: Of 65 male HP, 7 were HIV(+). Female IC were mostly IVDU (71%) and/or prostitutes (40%). Clinical and biological status of the IC were found to be associated with HIV prevalence in partners. A significant increase in transmission risk was found when couples had sexual contacts during menses. Other sexual practices (including anal sex), duration of relationship (median 2 years), frequency of sexual contacts, history of STD in the past 5 years and contraceptive behaviour were not found associated with partner infection.

		Nb couples	%(+,+)	P trend			Nb couples	%(+,+)	P
Clinical status	:Asymptomatic	42	4.8%		%T4	:≤15%	4	50.0%	
(N=63)	LAS/ARC	16	25.0%		(N=44)	15-20%	14	14.3%	
	AIDS	5	40.0%	0.005		>20%	26	7.7%	0.05
Sex during menses	:Never	40	5.0%		P24 Antigen	:Positive	8	25.0%	
(N=65)	At least once	25	20.0%	0.01	(N=28)	Negative	20	10.0%	NS

CONCLUSION:1)Female transmitters(HP+) were found to have more often clinical/biological symptoms of the HIV infection. 2)Compared with receptive anal sex, insertive anal-sex does not seem to be a high risk practice (for the male HP). 3)The presence of HIV infected blood cells in the vagina could explain the increase of risk observed in couples having contacts during menses.

Th.A.0.17 THE ROLE OF ULCERATIVE GENITAL DISEASES IN PROMOTING ACQUISITION OF HIV-1 BY HOMOSEXUAL MEN

VanRaden, Mark*; Kaslow, R.*; Kingsley, L.+; Detels, R.**; Marer, J.++; Murphy, R.***; Liang, K.-Y.++ and the Multicenter AIDS Cohort Study. *Bethesda, +Pittsburgh, **Los Angeles, ++Baltimore, ***Chicago, USA.

Objective. To evaluate the role of symptomatic ulcerative genital infections in promoting HIV-1 seroconversion (SC) in seronegative (SN) homosexual men.
Methods. Histories of sexual practices and STDs, physical examination, and EIA and Western blot tests for HIV-1 were available for SNs and SCs from semiannual examinations at 4 MACS centers between 1984 and 1988. We matched 219 SCs with 876 SNs by center, date of SC and level of receptive anal intercourse (RAI). Physical findings and RPR results within 6 months of SC and histories within 1 year of SC were analyzed. Matched data methods were applied in univariate and logistic regression analyses.
Results. Among matched SCs and SNs, 91% had RAI. In the 1 year period herpes was reported in 6.5% (genital only) and 9.2% (genital + anal) in SCs versus 5.1% (genital only) and 7.3% (genital + anal) in SNs. Matched odds ratios (ORs) for an effect of herpes were between 1.2 and 1.4 (All p >0.15). Only 3.2% of SCs and of SNs had syphilis. Neither history of syphilis nor RPR was related to SC (p >0.2). There was evidence for relationships between SC and sexual practices involving trauma (OR=1.8, p <0.05) and SC and condom use (OR=0.5, p<0.05). The relationships with genital ulcer disease remained non-significant after controlling for these factors, age and anal insertive sex.
Conclusion. We observed little association between symptomatic ulcerative genital disease and SC in the MACS. Anorectal trauma from sexual practices appears to have been a more important factor than these conditions.

Th.A.0.19 SEROLOGICAL EVALUATION OF SEXUAL PARTNERS,CHILDREN AND HOUSEHOLD CONTACTS OF HIV INFECTED PERSONS IN YAOUNDE-CAMEROON.

Marcel Monny-Lobe*,J-G Tsagadigui*,L.Zekeng**,R.Salla*,Kaptué
*Central Hospital Yaounde Cameroon,**University Teaching Hospital

Objective.To determine the modalities of transmission of HIV between an infected person and individuals he or she had contact with.
Methods.The study was conducted in Yaounde from September 1986 to July 1988, on 33 HIV infected persons(assymptomatic or ill) and 365 people who have been in contact with them.These people were tested early after the diagnosis of the patient contact.Amongst them,were: 38 sexual partners(they have never used preventive methods during sexual intercourse;one homosexual was included) 2 who have received contaminated blood(the patient contact was discoverd sero positive later after the blood transfusion); 8 children under two years old of seropositive mothers;and 317 people living in the same house,class-room,or job-site with the patients.
Results:On the 365 people considered, 34 (9,3%)were seropositive:(a)25/38(73%) sexual partners were seropositive,the homosexual was included;(b)the 2 recipients ofcontaminated blood were seropositive;(c)5/8 children were found sero positive;(d)2 positive cases were noted in the household contact group,but these 2 sisters had had sexual intercourse with a seropositive person.
Conclusion.The commonest way of transmission in Yaounde is sexual intercourse. Blood transfusion is a high risk mode of transmission because of inadequate blood screening before transfusion.Materno-foetal transmission too is a major mode in the country.There is no other means of transmission of the virus apart from those previously discussed.

Th.A.0.21 HIGH PREVALENCE AND INCIDENCE OF HIV AND OTHER SEXUALLY TRANSMITTED DISEASES(STD) AMONG 801 KINSHASA PROSTITUTES.

Laga, Marie***; Nzila, N*.; Manoka, AT*. ;Kivuvu, M*.; Behets, F*.; Edidi, B*.; Piot, P***.; Ryder, R*/**;
*Projet SIDA, Kinshasa, Zaire; **CDC, Atlanta, GA.; ***Institute of Tropical Medicine, Antwerp, Belgium

Objectives. To document prevalence and incidence of STD including HIV in Kinshasa prostitutes and to determine risk factors for HIV acquisition.
Methods. Over a period of 8 months in 1988, 801 female prostitutes were enrolled in a cross-sectional prevalence study on STD including HIV. HIV(-) negative women were then invited to participate in a cohort study with monthly STD exams. HIV serology was repeated every 3 months.
Results. 296(37%) of 801 women were HIV(+). Seventy-six percent of the women presented with at least one STD. There was no difference between HIV(+) and HIV(-) women regarding age (27 Y vs. 26 Y), mean number of partners/week (7.5 vs 7.8), duration of prostitution (54 mos. vs. 52 mos.), oral contraceptive use (12% vs 11%), regular condom use (29% vs 30%), prevalence of N. gonorrhoea(26 vs. 22%), C. trachomatis(15 vs. 11%) T. vaginalis(23 vs. 21%) and syphilis(20 vs. 17%). HIV infection was strongly associated with antibodies against H. ducreyi(54% vs. 21%), the presence of a genital ulcer(GU) (13 vs. 3.6%) and condylomata accuminata(CA) (5.6% vs. 1,2%). 210 initially HIV(-) women have been followed up monthly for a range of 3 to 8 months (1054 women months observation). Ten women seroconverted resulting in an incidence of 14%/year. Incidence of STD was 2 to 3 times higher in HIV seroincident cases (SI) compared to persistently HIV(-) women (PN).

Incidence of STDs*	N. gonorrhoea	C. trachomatis	T. vaginalis	GUD
SI (n=10)	2.6	2.6	4	0.4
PN (n=200)	1.4	0.8	1.5	0.2
	(p=0.1)	(p=0.01)	(p=0.02)	(p=0.9)

(* Expressed as episodes of infection per women year of observation)
Conclusions. HIV and other STD are highly prevalent among prostitutes in Kinshasa. H. ducreyi antibodies, presence of GU and CA were associated with HIV infection in the cross-sectional survey. Increased incidence of STD was concurrently documented with incidence of HIV.

Histoire clinique vers l'infection par le VIH : progression vers l'infection
Natural History of HIV Infection: Progression to Disease

Th.A.0.22 TIME-TO-AIDS AMONG 816 SEROCONVERTERS:

Seroconverters Working Group (by Robert J. Biggar, NCI, Maryland, USA)

Objectives. To examine time-to-AIDS among persons infected by HIV by different routes, in different geographic areas, and at different times.

Methods. 38 investigators provided data on 1115 seroconverters (111 AIDS cases). Analysis was restricted to 816 persons enrolled in prospective studies whose seroconversion date was known within 54 weeks. Subjects were from North America (52.1%), Europe (33.4%), and Australia (14.5%) and included 496 Homosexual men (HO); 265 Hemophiliacs (HP); 46 iv Drug Users (DU); and 10 heterosexually exposed partners (PT). Median follow-up was 3.0 years, and 111 persons had at least 6 years follow-up. AIDS risk was analysed by Kaplan-Meier methods using log-rank tests to compare time-to-AIDS in different groups.

Results. Within risk group, time-to-AIDS was the same in all area and among early (<1985) and later seroconverters. Children (<18 years old) progressed to AIDS more slowly than Adult HP (log rank p=0.003) and other groups. HO men progressed to AIDS more quickly than Adult HP patients (p=0.04) because of a propensity to develop Kaposi's sarcoma. Time-to-Pneumocystis carinii pneumonia was the same among HO men as it was among Adult HP. Too few DU (only 16 had been followed >24 months) and PT were available for assess the time-to-AIDS reliably.

CONCLUSIONS: HIV infection at different times and places was similar. Age is an important determinant to time-to-AIDS. Time-to-AIDS will depend in part on differing risks of the specific diseases seen in AIDS, but the time to same condition appears to be similar in HO and adult HP, suggesting a similar overall pathogensis.

Th.A.0.23 HTLV-I/II CO-INFECTION IS SIGNIFICANTLY ASSOCIATED WITH RISK FOR PROGRESSION TO AIDS AMONG HIV+ INTRAVENOUS DRUG ABUSERS.

Weiss, Stanley H.*; French J**; Holland B*; Parker NA*; Lin-Greenberg A***; Altman R**; et al. *UMDNJ-New Jersey Medical School, Newark;**NJ Dept Health,Trenton;***Jersey City Medical Ctr, New Jersey,USA

Objectives: Assess demographic & serologic factors that may affect risk of progression to AIDS among HIV+ IV drug abusers (DA) in New Jersey (NJ).

Methods: In 1984 we tested 268 IVDA from Spectrum Health Care in Jersey City for HIV as part of a prospective cohort study. To confirm AIDS outcome during the ensuing 50 months, we reviewed medical records & AIDS registry data. HTLV-I/II Ab was determined by concordance of 3 methods, and is associated with Black race & older age (SH Weiss, 3rd Intl AIDS Conf).

Results: None of 120 IVDA who were HIV- in 1984 had yet developed AIDS. Among the 148 HIV+ IVDA, there were 29 (20%) AIDS cases. AIDS was significantly associated with HTLV:

		# AIDS/TOTAL #	%AIDS	95% CONFIDENCE INTERVAL
HTLV-I/II	Negative	23 / 134	17%	11%, 24%
	Positive	6 / 14	43%	17%, 71%

(Fisher's exact test, p=.03). Kaplan-Meier life table analyses were similar (p=.02 at 50 months). The HTLV association held after adjustments for race, age and sex. Older age was also associated with AIDS.

Conclusions: Our prospective follow-up of prevalent HIV+ IVDA indicates that infection with HTLV-I/II was a significant marker for disease progression among IVDA. These data are consistent with in vitro models of HTLV-I activation of HIV. Since HTLV is associated with both IV drug use & age, it will be important to continue to observe seroconverters (who have yet to develop disease) to assess whether HTLV co-infection is etiologically important, rather than a marker for duration of HIV infection.

Th.A.0.24 CLINICAL PROGRESSION OF HIV-RELATED DISEASE IN INTRAVENOUS DRUG USERS (IVDU) IN A PROSPECTIVE COHORT STUDY: 1985-1989.

Selwyn, Peter A; Hartel D; Schoenbaum EE; Klein RS; Friedland GH. Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY, USA.

Objective. To study the natural history of HIV infection among HIV+ IVDU's (N=288) in a NYC methadone program enrolled in a prospective cohort study from 6/85-1/89.

Methods. Initial and follow-up data were analysed by uni- and multivariate analysis, including demographic, drug use, and clinical variables, to determine rates and risk factors for the progression of HIV-related disease.

Results. 55% patients(pts) were male; 13% white, 29% black, 57% Hispanic; mean age was 34 yrs. Mean follow-up was 31 mos.; 16% pts were lost to follow-up. 34(12%) pts progressed to AIDS(4.5/100 person-yrs.). In 28/34(82%)pts onset of constitutional symptoms (CS) preceded AIDS by a mean of 26 mos. In 25/34(74%)pts occurrence of bacterial pneumonia (BP)(n=6), tuberculosis (TB)(n=3),and/or OT(n=20) preceded AIDS by a mean of 9 mos. AIDS occurred in only 6/97(6%) pts without prior CS and 9/209 (4%) pts without prior BP, TB, or OT. Of 254 HIV+'s without AIDS, 163(63%) developed CS and 54/254(21%) developed BP(n=25),TB(n=4),and/or OT(n=41), at a mean of 20 mos. later than these findings had occurred in AIDS pts. All AIDS pts with results available had prior CD4 counts <400/mm3 vs. 47% pts without AIDS (P<.01). On regression analysis AIDS was predicted by CS (p<.04),BP or TB (p<.001),OT (p<.0001), and CD4/CD8 ratio (p<.03), and not by any drug use or demographic variables.

Conclusion. Data indicate frequent progression of HIV-related disease in our cohort of IVDU's; AIDS was predicted by a progressive pattern of clinical and immunologic findings. These same findings were common, but have occurred more recently, in HIV+'s without AIDS, suggesting that this group may simply be earlier in the course of HIV infection and at high risk for continued progression. Further study of AZT and other interventions in asymptomatic IVDU's is critical.

Th.A.0.25 PROGRESSION TO DISEASE IN WOMEN WITH KNOWN DURATION OF HIV INFECTION

ANZALA AGGREY, F PLUMMER, I WAMOLA, J NDINYA-ACHOLA, P WAIYAKI, J KREISS
U. Nairobi, Kenya Medical Research Institute; Nairobi. U. Manitoba, Winnipeg
U. Washington; Seattle.

OBJECTIVE: To determine the rate of development of disease in women with known duration of HIV infection.

METHOD: 111 initially seronegative prostitutes enrolled in a longitudinal study of sexual acquisition of HIV, in Nairobi, were followed at 6 months intervals from the time of documented seroconversion. At each visit women were evaluated for evidence of HIV related disease and classified as CDC HIV stages.

RESULTS:

CDC stages (%)

MONTHS	N	II	III	IV				
				T	Z	HL	CS	D
<6	111	31	65	3	2	-	-	-
6-12	69	17	70	6	4	-	3	-
13-18	52	15	65	10	6	-	4	-
19-24	42	12	60	17	7	-	5	-
26-30	20	5	30	35	15	5	10	-
31-36	14	-	7	50	21	7	14	-
37-42	14	-	-	50	21	7	14	7

T=thrush; Z=zoster; HL=hairy leukoplakia; CS=constitutional symptoms; D=death from AIDS

CONCLUSION: Women develop stage III disease rapidly after infection and after 3 years the majority have overt manifestations HIV infection.

Th.A.0.26 THE EFFECT OF AGE ON HIV PROGRESSION IN HEMOPHILIACS

James J Goedert*, ME Eyster, JE Drummond, MW Hilgartner, GL Bray, AR Cohen, et al. *NCI for the Multicenter Study of AIDS in Hemophiliacs, Bethesda MD 20892 USA.

Objective. To evaluate the effect of age on two phases of HIV disease--seroconversion to a subclinical marker, then marker to an AIDS diagnosis.

Methods. For 3 age groups we compared 1) the incidence of drop in T4 count, rise in interferon (IFN) and p24 antigen (Ag+, Abbott), and loss of p24 and gp120 antibodies (Ab-, RIA) and 2) AIDS incidence after each marker with actuarial methods and log-rank tests of significance. T4 and p24-Ag data were complete for only N=83, but other assays were evaluable for N=293.

Results. 49 AIDS cases occurred in 319 hemophilic subjects with known HIV-seroconversion dates. AIDS incidence (cases/100 person-years) increased with age at seroconversion: 0.8 for age 1-18, 2.3 for age 19-33, and 4.0 for age ≥ 34, p=0.00005. Older adults progressed to T4<400 faster than young adults (p<.001) with similar findings in rates to T4<300, T4<200, and p24-Ab- (p=.007, .02, .08). In contrast, children's rates to T4<400, <300, and <200 were identical to young adults' rates (p≥.84). Children did differ from older adults in cumulative rate to p24-Ab- (35% vs 78% p=.01) and in total AIDS rates after p24-Ab- (6% vs 63% p=.0007) and after T4<400 (7% vs 100% p=.06). Although few, children also tended toward lower rates of p24-Ag+ (18% vs 29% p=.11) and AIDS after p24-Ag+ (0% vs 70% p=.51). IFN≥20 and gp120-Ab- did not differ by age in incidence (5-28%) or later AIDS (p>.20).

Conclusion. HIV progression to T4<400 is more rapid in older adults than in younger adults or children, and opportunistic infections are less frequent in children than adults with similar degrees of immune deficiency.

Th.A.0.27 THE NATURAL HISTORY OF HIV INFECTION IN A COHORT OF MALE SEXUAL CONTACTS OF MEN WITH HIV DISEASE

Coates, Randall;Johnson, K.;Read, S.;Raboud, J.;Calzavara, L.;Farewell, V.;Fanning, M.;Shepherd, F.;Klein, M.;MacFadden, D. University of Toronto, Toronto, Ontario, Canada.

Objective: To describe current HIV morbidity in this cohort and to estimate the cumulative risk of developing AIDS from estimated time of HIV infection.

Methods: Since 1984, a cohort of 249 male sexual contacts of men with AIDS or HIV-related disease has been monitored three monthly for the development of HIV related illnesses according to the CDC Classification of HIV infections. A Kaplan-Meier analysis was conducted to estimate the cumulative probability of developing AIDS from the estimated date of infection in the seropositive sexual contacts. The surrogate measure of date of infection in these individuals was the date of first sexual contact with the index cases.

Results: According to the most recent clinical data, 159 cohort members are seropositive. Of these, 15 were Group II (9.4%), 104 were Group III (65.4%), and 40 were Group IV (25.1%) (23 IVC1, 5 IVC2, 11 IVD, 1 IVE). Sixty-six percent of Group II infections had normal immune function in contrast to only 30% of Group III infections at their most recent review. Estimates of the risk of developing AIDS following the initial sexual contact with the index cases in seropositives are as follows: 5.4% after 3 years, 9.7% after 4 years, 19.9% after 5 years, 31.5% after 6 years, 34.5% after 7 years, 41.1% after 8 years, 45.7% after 9 years, and 45.7% after 10 years.

Conclusion: Persistent generalized lymphadenopathy is a common manifestation of HIV infection and the cumulative risk of developing AIDS continues to rise the longer one has been infected.

Infection par le VIH et travailleurs de la santé : questions actuelles
HIV Infection and the Health Care Worker: Contemporary Issues

Th.A.O.28 HIV INFECTION AND THE HEALTH CARE WORKER: CONTEMPORARY ISSUES

Chairpersons: Robert J. Pratt (London, United Kingdom)
Walter F. Schlech, III (Halifax, Canada)
Panelists: David M. Bell (Atlanta, USA), J. Louise Geberding (San Francisco, USA) Fred M. Gordin (Washington, USA), Bosenji Ngaly (Kinshasa, Zaire)

Transmission of HIV infection has been documented in the health care setting. This roundtable will discuss real and perceived occupational risks in caring for HIV-infected patients, and the role of universal precautions in decreasing risk, current policies and practice surrounding the infected health care worker (HCW), and the risks of transmission to patients by the infected HCW. Data on the attitudes and practices of HCW's towards HIV infected-patients will be summarized. Discussion will also focus on differences in occupational risks between developed and developing countries and the feasibility of universal precautions in each setting. Emphasis will be placed on the costs of instituting universal precautions in comparison to the costs of selected or universal screening programs for hospitalized patients. Practical and ethical issues will be highlighted in the implementation of universal precautions or screening programs emphasizing the changing demographics of the HIV pandemic.

Autres rétrovirus : le HTLV-I
Other Retroviruses: HTLV-I

Th.A.O.29 HTLV I AND HTLV II INFECTION IN U.S. BLOOD DONORS

Burczak, J.*; Fang, C.**; Leete, J.*; Schrode, J.*; Laitila, V.*; and Lee, Helen* *Abbott Laboratories, North Chicago, IL, USA **American Red Cross, Rockville, MD, USA

OBJECTIVE. With the advent of large scale HTLV I screening, the rate of HTLV I/II infection was determined in over 300,000 blood donors from all parts of the U.S.
METHOD. A viral based EIA was used in the initial screening followed by confirmation using Western blot (WB), SDS-PAGE RIPA, PCR and lymphocyte coculture in certain subjects.
RESULTS. A total of 301,109 donors were screened by EIA for an initial reactive rate of 0.11% and a repeat reactive rate of 0.08% with 248 EIA repeat reactive donors identified to date. Approximately one-third of these were resolved by WB alone (14% WB positive, 19% WB negative), whereas the remaining two-thirds needed to be tested by RIPA. A further 26% were confirmed to be positive by RIPA (using the FDA/CDC guidelines of antibodies to 2 gene products). The remaining samples (39.6%) were negative by RIPA. None of the WB negative samples tested positive by RIPA.
CONCLUSION. The distribution of confirmed positives indicates a high density of HTLV I infection in metropolitan areas such as San Francisco, LA, New York and Miami, superimposed by a belt in the Southern regions extending from California through Texas and Florida to South Carolina. PCR results using lymphocytes from over 40 donors indicate that both HTLV I and II are present, with the majority being HTLV I. This is in contrast to our findings in IVDA from New Orleans which indicated an overwhelming majority (>90%) of HTLV II infection in the cohort studied.

Th.A.O.31 HTLV-I-ASSOCIATED MYELOPATHY (HAM/TSP) IS ASSOCIATED WITH BLOOD TRANSFUSION

Osame,M.*; Janssen, Robert**; Igata,A.*; Kubota,H.*; Nishitani, H.***;Khabbaz, R.**. *Kagoshima University, Kagoshima, Japan, **Centers for Disease Control, Atlanta, Georgia, USA, ***Utano National Sanitorium Hospital, Kyoto, Japan.

Objective. To determine whether HTLV-I-associated myelopathy/tropical spastic paraparesis (HAM/TSP) is associated with blood transfusion. Methods. National surveys of HAM/TSP in Japan in 1987 and 1988. A case of HAM/TSP was defined as a slowly progressive myelopathy with antibodies to HTLV-I both in serum and CSF. Results. In the surveys, 589 cases of HAM/TSP were reported. Significantly more HAM/TSP patients reported a history of blood transfusion (26%) than did HTLV-I infected patients with adult T cell leukemia/lymphoma (15/122, 12.3%, p < .002), or than did the general population (Kagoshima district, 41/1290, 3.2%, p < .001). Modeling of the distribution of the interval from transfusion to onset of HAM (median=33 months) followed a log-normal distribution, the expected distribution if transfusion is associated with HAM/TSP. In November 1986, all Japanese blood banks stopped transfusing HTLV-I seropositive blood. Significantly fewer HAM/TSP patients whose symptoms began after screening reported a history of blood transfusion (11/59, 18.6%) than did patients whose symptoms began during a comparable period before screening (33/89, 37.1%, p=.03). Furthermore, only 1 person who developed HAM/TSP in 1987-1988 reported a history of blood transfusion after 1986 compared to 9.2 expected cases if no screening had taken place (p=.007). Conclusions. These results demonstrate an association between blood transfusion and HAM/TSP and suggest that transfusion of HTLV-I-infected blood can cause HAM/TSP.

Th.A.O.33 SIGNIFICANCE OF POSITIVE AND INDETERMINATE HTLV-1 SEROLOGIC RESULTS IN BLOOD DONORS.

Khabbaz, Rima*; Lairmore, M.*; Lee, H.**; Critchley, S.***; De, B.*, and Shulman, G.***. *CDC and ***American Red Cross Atlanta Region, Atlanta, Ga, and **Abbott Laboratories, Chicago, Il, U.S.A.

Objective. To evaluate virologic and epidemiologic characteristics of blood donors whose HTLV-I serologic results were positive or indeterminate. Methods. From June-August 1988, sera from 19996 consenting blood donors of the Atlanta Regional Blood Services were tested for HTLV-I antibody by EIA; all reactive sera were confirmed by WB and RIPA. Interviews and a second blood specimen were obtained from all HTLV-I-positive donors, and from 3 donors with indeterminate and negative serologic results; peripheral blood mononuclear cells were examined by polymerase chain reaction (PCR) using 2 pol primer pairs specific for HTLV-I and HTLV-II, respectively. Results. Of 19996 blood donors tested, 20 (0.1%) showed repeatable reactivity by EIA; 3 (0.015%) were confirmed seropositive (presence of antibody to p24 and env gene product), and 15 (0.075%) had indeterminate results (reactivity to gag only). All 3 seropositive donors were black and from the SE, compared with 1/3 with indeterminate and 0/3 with negative results. None gave a history of iv-drug use, but 1 positive donor had an iv-drug-using sex partner. The HTLV-I seroreactivities remained unchanged 4-7 months after initial donation. Cells from 1 of 2 positive donors showed HTLV-I specific sequences on PCR; cells from the other showed HTLV-II. In contrast, cells from 2 of 2 with indeterminate (both with p19 only on WB) and 3 of 3 with negative serologic results were negative for both. Conclusion. HTLV-I seropositivity in blood donors may be due to HTLV-I or HTLV-II; donors with indeterminate HTLV-I serologic results may not be infected with either HTLV-I or HTLV-II

Th.A.O.30 ANTIBODIES TO HIV-1 AND HTLV-1 IN HAITI

Elie,Robert*;Chout,R.**;Lassegue,A.*;Dorlette,J.*;Cesar,D.*, Delaunay,B..*Laboratoire d'Investigations Biologiques, Port-au-Prince, Haiti; **Hopital du Lamentin, Lamentin, Martinique.

Objective. Determine the seroprevalence of HTLV-1 antibodies (Ab) and the association of HIV-1 and HTLV-1 in Haiti.
Methods. From september 1987 to september 1988, 896 apparently healthy individuals, (16-79 years of age, x: 30 ± 14 years, 503 female, 379 male), 107 adults AIDS patients (43 female, 64 male) and 105 female prostitutes were tested by Elisa for Ab to HIV-1 (Abbott and Dupont) and HTLV-1 (Dupont). Positive specimens were tested by Western blot (Dupont).
Results. Specimens were considered positive only when reactive by Western blot. The following table summarizes the results.

Serology	Healthy (896)	Prostitutes (105)	AIDS patients (107)
HIV-1+	51 (5.8%)	68 (36.7%)	107 (100%)
HTLV-1+	22 (2.5%)	9 (15.7%)	11 (10.3%)
HIV-1+/HTLV-1+	7 (0.79%)	23 (12.4%)	11 (10.3%)

The seroprevalence of HIV-1 and HTLV-1 Ab among apparently healthy haitians is 5.8% and 2.5% respectivly. The prevalence of the HIV-1 / HTLV-1 co-infection is 0.79% among healthy individuals, 10.3% among AIDS patients and 12.4% among prostitutes.
Conclusion. The results indicate that the seroprevalence of HTLV-1 in Haiti is the same as in other Caribbean islands. They also suggest that prostitutes are particularly at risk for HTLV-1 infection. Cohort studies should be carried out in Haiti to determine the influence, if any, of HTLV-1 on the evolution of HIV-1 infection.

Th.A.O.32 HTLV-I INFECTION CORRELATES WITH INCREASED AGE IN INTRAVENOUS DRUG USERS (IVDU)

Horsburgh, C. Robert*; Hartel, D.**; Khabbaz, R.***; Lairmore, M.***; Klein, R. S.**; Friedland, G.**
*AIDS Program, and ***Division of Viral Diseases, CDC, Atlanta GA USA,
**Montefiore Medical Center, Bronx NY USA

Objective. To evaluate risk factors for HTLV-I infection in a cohort of IVDU.
Methods. Subjects were participants in a longitudinal study of HIV infection in IVDU in a methadone maintenance program in Bronx NY. All participants who had blood drawn in 1987 were tested for serologic markers of HTLV-I infection. Samples were screened by enzyme immunoassay and confirmed by Western blot and radioimmunoprecipitation.
Results. Of 270 persons, 21 (8%) were HTLV-I+ (antibody to p24 and env gene product), while 12 (4%) had indeterminate results (antibody to gag gene product only), and 237 were HTLV-I-. HTLV-I+ persons were significantly older than HTLV-I- persons (p=.0001). No significant differences were seen in sex, race, socioeconomic status, transfusion history, birthplace, or travel to HTLV-I endemic areas. Both HTLV-I+ and HTLV-I- IVDU had similar duration and frequency of drug use, history of needle sharing with strangers, and visits to shooting galleries since 1978. Moreover, no differences were seen in number of total, IVDU, or paying sex partners since 1978. HTLV-I+ and HTLV-I- persons had similar rates of HIV infection. Analysis controlling for age did not reveal additional risk factors.
Conclusion. In this cohort of IVDU, HTLV-I seropositivity was more common in older persons; neither sexual nor drug use behaviors since 1978 were associated with the acquisition of HTLV-I.

Th.A.O.34 PREVALENCE OF HUMAN T-LYMPHOTROPIC VIRUS TYPE 1 IN APPLICANTS FOR THE UNITED STATES ARMED FORCES

Figgs, Donald*; Hern, W.**; Alexander, S.***; Damato, J.****; Brundage, J.****; and Burke, D.**** *William Beaumont Army Medical Center, El Paso, TX, **Bowling Green State University, Bowling Green, OH, ***BioTech Research Laboratories, Rockville, MD, **** Walter Reed Army Institute of Research, Washington, DC, U.S.A.

Objective. To determine the prevalence of antibodies to human t-lymphotropic virus type 1 (HTLV-1), the cause of adult T-cell leukemia (ATL) and tropical spastic paraparesis (TSP), in civilian applicants for the armed services of the United States.
Methods. Sera from 10,939 applicants collected during the period of March and April 1988 were screened using a enzyme linked immunosorbent assay (ELISA). All repeat reactive and 14 initial reactive ELISA samples were blind tested by Western blots and radioimmunoprecipitation assays (RIPA) to confirm the presence of antibodies specific to HTLV-1.
Results. Of the 233 (2.23%) initial reactives by ELISA, 55 (0.50%) were repeatedly reactive. The Western blot procedure revealed 5(7.2%) positive, 20(29.0%) negative, and 44(63.7) indeterminate. The RIPA confirmed the presence of envelope protein in 2 of the 5 Western blot positives and in 3 of the 44 indeterminates for a total of 5 confirmed positives.
Conclusion. The overall prevalence rate of HTLV-1 antibody in the applicants was 0.45 per thousand.

Études séro-épidémologiques sur la prévalence du VIH
Seroepidemiologic HIV Prevalence Studies

M.A.P.1 PREVALENCE OF HIV INFECTION AMONG U.S. ARMY RESERVE COMPONENT PERSONNEL

Cowan David N*, Brundage J*, Miller R*, Goldenbaum M*,Pomerantz R**,Wann F**
*Walter Reed Army Institute of Research, Washington, DC USA **SRA Technologies, INC, Alexandria, VA USA

Objective. To evaluate the prevalence of HIV infection among members of the Army Reserve Components (RC), a population which may provide unique insight to the dynamics of the HIV infection epidemic among adults in the U.S.
Methods. As of 30 September 1988 545,114 members of the RC had been tested for antibodies to HIV. Reservists are a primarily civilian group who spend about 10% of their days in a military environment.
Results. Prevalence among males was 1.62 (per 1000), and 0.84 in females. Among whites the prevalence was 0.59, 3.15 among Hispanics, and 4.52 among blacks. Prevalence varied with age, from 0.17 among those aged 19 or less, to a peak of 2.63 in those 30-34. There were 20 positives aged 50 or more, for a prevalence of 0.79. Among females, marital status was not significantly associated with infection. Among males, the prevalence varied greatly by ethnicity and marital status. For whites, the prevalence for currently married and never married was, respectively, 0.30 and 1.09. Among Hispanics, the prevalence was 2.16 and 5.46, respectively, and among blacks it was 3.11 and 6.96. Results of multivariate analyses will be provided to assess independent determinants of seropositivity.
Conclusions. These data demonstrate that risk of infection is significantly higher among males (particularly those never married) and among members of racial/ethnic minorities. While prevalence increases with age from the teens to the thirties, significant infection exists through at least the sixth decade.

M.A.P.2 HIV PREVALENCE AMONG MILITARY WOMEN: An Examination of Military Applicant, Active Duty, and Reserve Testing Data.

Horton, Jacqueline; Alexander, L. and Brundage, J.
Walter Reed Army Institute of Research, Washington, DC USA

Objective. To evaluate cumulative infection risk and demographic correlates of infection status among young women routinely screened for antibody to HIV.
Methods. Women represent 16% of applicants for military service, 11% of active duty members of the U.S. Army, and 17% of members of the Army Reserve components. Since October 1985, 383,112 women in these military-associated populations have been routinely screened for antibody to HIV. Data from these programs were analyzed to document cumulative infection risks and demographic correlates of antibody status (*i.e*, age, race/ethnicity, marital status).
Results. Crude seroprevalences were similiar among the three groups of women (applicants, 0.7/1000; active duty, 0.9/1000; reserves, 0.8/1000). In each group, prevalences among teenage females were comparable to those among teenage males. Prevalences increased with age from the late teens through the early thirties, and were particularly high among black non-Hispanic women. Marital status was not an independent determinant of antibody status.
Conclusions. Among females who apply for, or who serve in the military, infection risk begins in the teens and continues through young adulthood. Among teenagers, prevalences among females and males are comparable. Black females, especially those in urban epicenters, are at particular risk. These data enforce the need for socioculturally-sensitive prevention efforts targeted at women, regardless of marital status, from adolescence through the childbearing years.

M.A.P.3 HIV PREVALENCE RATES AND TRENDS IN ENDEMIC AND NON-ENDEMIC METROPOLITAN AREAS IN THE UNITED STATES, 1985-1988

Gardner, Lytt; Brundage, J.; Burke, D. and Miller, R.
Walter Reed Army Institute of Research, Washington, DC, USA.

Objective. To determine if geographic and population factors associated with the HIV infection epidemic differ for metropolitan areas with elevated rates early in the epidemic compared to those which exhibited modest rates early in the epidemic.
Methods. Since 1985, approximately 2 million civilian applicants for military service have been tested for HIV antibody, with an overall positivity rate of 1.4 per thousand. Prevalence (prev) rates for birthyear cohorts were calculated for 16 populous counties representing endemic locations (ave. 1985-1986 prev=3.88 per 1000), and for 12 populous non-endemic counties (ave. 1985-1986 prev=1.55 per 1000). The locations were classified down to the level of postal zip code and contrasted for prevalence rates, population density, and other characteristics.
Results. The endemic areas reported progressively decreasing rates (3.88, 3.55, 3.08 per 1000) from 1986-1988, compared to slightly increasing rates (1.55, 1.60, 1.73 per 1000) in the non-endemic areas over the same period. Percent of zip codes reporting at least one case was higher in endemic areas (22.3%) compared to non-endemic areas (11.4%). Average population density of zip codes with cases in affected endemic locations nearly doubled, while that for non-endemic areas dropped by 40%. The average percent of black residents was stable in zip codes with cases in endemic areas but increased by 25% in zip codes with cases in non-endemic areas.
Conclusion. These data suggest that in endemic locations, the HIV epidemic has become concentrated into zip codes with higher population density, wheras in non-epidemic locations, the epidemic is expanding over time into zip codes with lower population density and a greater percentage of black residents. These trends in HIV prevalence and demographic factors associated with zip code of cases provide insight into the natural histories of the epidemics in metropolitan locations in the United States.

M.A.P.4 SURVEILLANCE FOR HIV INFECTION IN THE ACTIVE DUTY U.S. ARMY: OVERALL SEROPOSITIVITY AND TRENDS FROM 1985 TO 1988.

Kelley, Patrick*; Pomerantz, R. **; Wann, F.**; Brundage J.*; Burke D.*; Miller R.* and the Walter Reed Retrovirus Research Group*. * Walter Reed Army Institute of Research, Washington, DC, ** SRA Technologies, Inc., Alexandria, VA, USA

Objective. To summarize overall U.S. Army HIV seropositivity and secular trends from 1985 to 1988.
Methods. Over 1,131,000 HIV serologic evaluations have been completed on active duty U.S. Army personnel since October 1985. After adjustment for multiply-tested soldiers, data on 727,444 soldiers were analyzed both in the aggregate and after partitioning the tests into those done prior to 1987 (N= 360,922 people), those during 1987 (N= 348,125), and those subsequent to 1987 (N= 249,748). Demographic data from semiannual Army personnel files were merged with test data to complete the analysis data set. Antibody positive soldiers appear only in the seropositivity numerator for the interval the infection was first documented.
Results. A total of 1570 soldiers had HIV antibody (2.16/1000 persons). Reflecting the effect of pre-accession HIV screening and repeat screening while on active duty, the temporal trend showed decreasing rate estimates (2.87/1000 before 1987, 1.22/1000 in 1987, and 0.44/1000 in 1988). Cumulative data showed high rate ratios (RR) for blacks and Hispanics relative to whites (3.83 and 3.33 respectively). Similarly, males (vs. females) had a rate ratio of 2.62. Though single soldiers had a higher risk of positivity (RR=1.70), 50.1% of the HIV positive soldiers either are or were previously married. For none of these variables was a significant temporal trend in the rate ratios noted in univariate analyses. The rate for black female soldiers is higher than that found for white male soldiers (RR=1.22, 95% CI= 0.91,1.64). To adjust for confounding by a variety of variables including age at the most recent test, a logistic regression of the cumulative data was performed with resultant adjusted odds ratios of 3.93 for being male, 3.48 and 3.12 for being black or Hispanic (vs. white) respectively, and 4.76 and 1.97 for being single or previously married (vs. married) respectively.
Conclusions. Consistent with previous reports, high risk demographic groups include black and Hispanic minorities (to include females), males, and those who are unmarried. Preliminary data do not indicate any significant temporal changes in the degree of excess risk for these groups relative to baseline groups.

M.A.P.5 PREVALENCE OF HIV INFECTION IN HETEROSEXUAL PERSONS IN THE UNITED STATES, 1988-89

Onorato, Ida; Peterson, L; Pappaioanou, M.; and Dondero, T.
AIDS Program, Centers for Disease Control (CDC), Atlanta, GA, USA.

Objective. To determine the prevalence of HIV infection in heterosexual persons in the U.S. and to assess risk factors for seropositivity.
Methods. The CDC Family of Surveys conducts sentinel surveillance of HIV infection in segments of the general population and in groups with varying risks of infection. We report data collected through April 1989 from population-based surveys of blood donors, military applicants, and child-bearing women and from surveys of 66 sexually transmitted disease (STD) and 84 women's clinics and 42 drug treatment centers (DTC) in 28 U.S. cities.
Results. Heterosexuals tested in population-based surveys showed low prevalences of HIV infection (0.012-0.66%). Preliminary data from clinic surveys of women attending prenatal, family planning and abortion clinics showed rates of 0-4.5% (median 0%). Heterosexual denying intravenous (IV) drug use in STD clinics had rates of 0.4-5.6% (median 1.4%). The highest rates (35%) were observed in DTC. Areas with high rates of HIV infection in DTC also had the highest rates in STD clinic clients. Rates varied by geographic region and was highest in large cities in the Northeast.
Conclusion. These results suggest that heterosexuals at highest risk of HIV infection are intravenous drug users. In the absence of IV drug use, heterosexuals whose sexual behaviors are associated with STDs had higher rates than other populations tested. In many areas of the US, transmission of HIV is still principally limited to persons practicing well-defined risk behaviors; however, this will continue to be monitored closely.

M.A.P.6 PREVALENCE OF HIV ANTIBODIES IN CHILDBEARING WOMEN IN FLORIDA

Withum, D.G.*; LaLota, Marlene*; Holtzman, D.*; Buff, E.E.*; Chan, M.S.*; Lieb, S.*; et al.
*Department of Health and Rehabilitative Services, Tallahassee, Florida, USA

Objective. To obtain an unbiased estimate of the levels and trends of HIV infection in women bearing live children in Florida.
Methods. Utilizing the state metabolic screening program, neonatal blood specimens routinely collected on filter paper were tested for HIV antibodies using the enzyme-linked immunosorbent and mini (Western) blot assays. Demographic data, such as county of birth and mother's race were also collected.
Results. Between July 1 and December 31, 1988, 306 of 65,007 (0.47%) filter paper specimens tested positive for HIV antibodies. The number positive/number tested (% positive) for HIV antibodies by mother's race for selected metropolitan counties and Florida for 1988, is shown below. The cumulative number of female AIDS cases is shown for comparison.

COUNTY OF BIRTH	MOTHER'S RACE		TOTAL	FEMALE CASES (CUM.)
	WHITE	NON-WHITE		
Dade	22/7501(0.29)	81/4980(1.63)	103/12481(0.83)	280
Broward	10/4210(0.24)	41/2067(1.98)	51/6277(0.81)	121
Palm Beach	13/3014(0.43)	37/1276(2.90)	50/4290(1.17)	138
Duval	07/3174(0.22)	06/1392(0.43)	13/4566(0.28)	22
FLORIDA	81/46323(0.17)	225/18684(1.20)	306/65007(0.47)	769

Conclusion. 65,007 (70.7%) of approximately 92,000 samples screened for metabolic disorders were tested for HIV antibodies. Analysis of demographic data on specimens not tested will be completed by March. If detailed evaluation supports the preliminary results, an estimated 1,000 Florida women giving birth in 1989 may demonstrate HIV antibodies.

M.A.P.7 SEROPREVALANCE OF ANTIBODIES TO THE HUMAN IMMUNODEFICIENCY VIRUS (HIV) in APPLICANTS FOR MARRIAGE LICENSES IN ALABAMA

Richard Moody*, Lu Ann Foss*, Jeannine Parker*, William Callan*, Donald Williamson**
*Alabama Department of Public Health (ADPH), Bureau of Clinical Laboratories (BCL), Montgomery, AL
**ADPH, Bureau of Disease Control and Rehabilitative Services, Montgomery, Alabama U.S.A.

Objective. To estimate the seroprevalence of antibodies to HIV in marriage license applicants (A presumed heterosexual, low risk population) in a low prevalence AIDS area using repeated studies.
Methods. All specimens submitted to the ADPH-BCL for routinely required premarital syphilis serology from 1 November, 1987, to 31 January, 1988 (study I), from 1 November, 1988, to 31 January, 1989 (Study II) were tested for HIV antibodies in separate anonymous studies using Abbott enzyme immunoassay (EIA). Repeatedly reactive specimens were tested by Western blot.
Results. 4694 specimens from Study I and 4637 specimens from Study II yielded the following:

RESULT	STUDY I (Number)	(%)	STUDY II (Number)	(%)
EIA+/Blot+	10	0.21	5	0.11
EIA+/Blot-	53	1.13	1	0.02
EIA+/Blot Indeterminate	7	0.15	1	0.02
Unsatisfactory	1	0.02	0	0.00
EIA-	4623	98.48	4530	99.85
Total	4694	100.00	4537	100.00

Conclusion. The decline in EIA+/Blot+ specimens from 0.21% to 0.11% does not appear to be statistically significant. These results fall between the observed seroprevalence among Alabama military recruits (0.07%, 1-3-88) and STD clinic clients (2.6%, 10-12-88).
Assuming 100% sensitivity during both study periods an increase in specificity from 98.72% to 99.96% reflects overall improvements in manufacture of the test kits and purification of the antigen.

M.A.P.8 ANONYMOUS HIV TESTING ON NEWBORNS IN 63 ITALIAN HOSPITALS: AN ESTIMATE OF PREVALENCE OF HIV INFECTION AMONG WOMEN IN REPRODUCTIVE AGE.

Ippolito, Giuseppe; Angeloni,P.; Stegagno, M.; Mannella, E.; Angeloni, U.; Costa, F.; Guzzanti, E.
Italian Collaborative Study Group for HIV Prevalence in Newborns, Lazzaro Spallanzani Hospital for Infectious Diseases, Rome, Italy.

Objective. To assess the prevalence of HIV infection in female population in reproductive age and provide a predictive parameter to estimate future pediatric AIDS cases.
Methods. Blood samples were collected on filter paper for routine screenings from 20,683 consecutive newborns in 63 hospital nurseries, in different Italian regions, during the period June- November 1988. Blood saturated disks were punched out from the collection papers, without identification, at the National Blood Transfusion Center of the Italian Red Cross, eluted in PBS and the screened for anti-HIV antibodies (HIV-Ab) in ELISA (Pasteur Labs); the positive results were confirmed in a Western Blot (Dupont Labs).
Results. Among the 20,683 blood samples tested 18 (.00087, Confidence intervals 95%, Poissons Distribution .00052--.0014) were found positive for HIV-Ab.
Conclusion. The distribution pattern of the positive samples among the different regions correlates to the AIDS cumulative incidence rate, with a higher prevalence in northern and central Italy. HIV screening on the newborns, who reflect serological pattern of the respective mothers, can provide an useful tool in evaluating the prevalence of the infection in a relatively unselected population.

M.A.P.9 HIV SEROPREVALENCE ON UNIVERSITY CAMPUSES, U.S.A.

Gayle, Helene*, Keeling,R**, Garcia-Tunon,M**, Kilbourne,B* Narkunas,J*.
*Centers for Disease Control (CDC), Atlanta, GA, USA,
**American College Health Association, Rockville, MD, USA

Objective. To estimate the seroprevalence of HIV infection among university students in the United States.
Methods. We are conducting blinded HIV antibody testing on blood collected for other routine medical purposes in student health centers. A total of 500-1000 blood specimens are being collected on 17 campuses throughout the country and tested for HIV antibodies by ELISA and Western blot. Non-identifying demographic data are linked with test results.
Results. To date, a total 23 (0.2%) of 13,810 specimens are positive for HIV antibodies. All positive results are from students >18 years old; 17 (83%) were >21 years old. Twenty (87%) of students with positive results were male. Seroprevalence rates were higher for males (0.49%) than females (0.04%) and increased with age from 0.06% for 18-21 years olds to 0.66% for 26-29 years olds. Positive results were identified in only 5 of the 17 schools; however, these schools represented all regions of the country.
Conclusions. HIV infection is present on university campuses, although, the rate still appears to be relatively low. These data suggest that older, male students are at greatest risk. Universities provide a challenge to maintain low rates of seroprevalence in what is often a relatively insular setting with high rates of sexual activity, often with multiple partners. Additionally, the risk of exposure to HIV infection may increase for many students as they leave the campus, highlighting the importance of targeting this population.

M.A.P.10 HIV SEROPREVALENCE AT THE BRONX LEBANON HOSPITAL CENTER - A CDC SENTINEL HOSPITAL

Ernst, Jerome A.*; Bauer, S.*; Amaral, L.*; St. Louis, M.**; Falco, I.*
*Bronx Lebanon Hospital, Bronx, NY, USA, **CDC, Atlanta, GA, USA.

Objective. To monitor levels and trends of HIV seroprevalence in the South Bronx.
Methods. The CDC Sentinel Hospital Surveillance Network's protocol and sampling system was used. From Feb.- Oct. 1988, 2566 bloods were tested. They came from 871 males and 1695 females; 1195 Blacks, 1181 Hispanics, 21 Whites and 169 of unknown origin.
Results. The population's mean age was 41.8; males 43.9 and females 40.1. Western blot positive males had a mean age of 39.8 and positive females 34.8. 70 males and 70 females were positive. The ages and results are listed below:

Age Group	Male	Female	Total	Male WB+	(%)	Female WB+	(%)	Total WB+	(%)
0-4	57	24	81	0		1	(4.2)	1	(1.2)
5-14	12	17	29	0		0		0	
15-24	56	315	371	2	(3.6)	8	(2.5)	10	(2.7)
25-44	245	630	875	46	(18.8)	49	(7.8)	95	(10.9)
45-64	355	426	781	20	(5.6)	12	(2.8)	32	(4.1)
65+	146	283	429	2	(1.4)	0		2	(0.5)
Total	871	1695	2566	70	(8.0)	70	(4.1)	140	(5.5)

Conclusion. Bronx Lebanon Hospital has one of the highest HIV seroprevalence rates in the Sentinel Hospital Network suggesting the urgency of intensive, community-wide interventions to control further transmission of HIV in this high-risk, urban population.

M.A.P.11 INCIDENCE OF HIV SEROCONVERSION IN U.S. NAVY PERSONNEL: RESULTS OF TOTAL NAVY SCREENING

Garland, Frank*; Mayers, D. **; Hickey, T.***; Miller M.*; Bigbee L.****; and the Navy Retroviral Study Group.
*Naval Health Research Center (NHRC), San Diego, CA, **National Naval Medical Center, Bethesda, MD, ***Naval Medical Command, Washington. D.C., ****Defense Eligibility Enrollment Reporting System (DEERS), Monterey, CA. U.S.A.

Objective: To determine incidence rates of HIV seroconversion in a young and apparently healthy population of active-duty U.S. Navy and Marine Corps personnel.
Methods: Using HIV seropositivity data provided by the Naval Medical Command and maintained in the Navy HIV Central Registry at NHRC, and population data provided by the Reportable Disease Database of DEERS, incidence rates of seroconversion were calculated for the period 1986-1988 using person-years at risk as denominators. The period at risk for each individual began with the first negative ELISA test and continued until the first positive Western blot assay or the last negative ELISA test. HIV seroconverters were defined as persons with at least one negative ELISA screening test followed by two positive paired ELISA tests and two positive Western blot assays (criteria for positive Western blot: a specimen that exhibited at least two of three bands at p24, gp41, and gp120/160).
Results: Since 1986, 97% of active-duty Naval personnel have had a routine annual HIV seropositivity screening test (1,070,511 persons; 1,956,631 tests). During the three-year period 1 Jan 1986 to 31 Dec 1988 there were more than 725 seroconversions in active-duty personnel. Incidence rates of seroconversion over time and by age, race, sex, occupation, and other relevant demographic characteristics were determined.
Conclusion: This is one of the largest studies in existence of HIV seroconversion in a non self-selected healthy population. It provides unique information on demographic and occupational factors related to HIV seroconversion.

M.A.P.12 HIV SEROPREVALENCE AMONG PARTURIENTS IN LOS ANGELES COUNTY, 1988

Hill, Deirdre*, Kerndt, P.*, Frenkel, L.M.**, Settlage, R.**, Lee, M.** Yonekura, M.**, et al.
*Los Angeles County Department of Health Services/(LACDHS), Los Angeles, California, USA
**Pediatric/Perinatal AIDS Task Force, LACDHS, Los Angeles, CA, USA

Objective. To estimate the prevalence of human immunodeficiency virus (HIV) among parturients in County Hospitals in Los Angeles County.
Methods. Between September and December 1988, 9,400 consecutive placental cord blood specimens were obtained from four County Hospitals in Los Angeles County. Specimens were linked to maternal demographic information and, when available, prenatal syphilis serology and risk factors for HIV infection. An ELISA test was done after all personal identifiers were removed. Repeat ELISA positives were confirmed by immunofluorescent antibody and Western Blot.
Results. The combined total births in this sample represents approximately 38% of all Hispanic births, 23% of all black births, and 8% of all white births in LAC in the sampling period. To date, 0.04% (3/7,186) have been confirmed HIV Ab positive. Sixty-two percent of all women had information available on intravenous (IV) drug use, and of these, approximately 5% had a history of IV drug use, but none were HIV Ab positive. Of the women for whom information was available, 2.9% had a positive syphilis test at the time of delivery, but again none were HIV Ab positive.
Conclusion. HIV seroprevalence among parturients delivered at county hospitals in LAC during the sampling period was low, and was not associated with either IV drug use or syphilis. Data from 9,400 births will be presented.

M.A.P.13

DEMOGRAPHICS OF HIV INFECTION IN THE UNITED STATES AIR FORCE (USAF) PERSONNEL

Zajac, Robert*; Lacey, D.E.*; Melcher G.P.*; Weisenfeld, D.**; Abbadessa, S.*; Boswell, R. Neal*; et al.
*Dept of Internal Medicine, Wilford Hall USAF Medical Center, Lackland AFB, TX,
** Environmental Health Service, Wilford Hall USAF Medical Center, Lackland AFB, TX. U.S.A.

OBJECTIVE: To describe the characteristics of the USAF HIV cohort.
METHODS: Clinical and immunological evaluation by Walter Reed (WR) staging criteria.
RESULTS: In September of 1988 with completion of force-wide screening of USAF personnel (including Reserve and National Guard), a total of 889,730 sera were tested; of these 841 were positive for HIV antibody by ELISA x 2 and Western Blot, for a prevalence of 0.95/1,000. A total of 609,664 sera from Active Duty (AD) personnel were tested; 582 were positive for a prevalence of 0.95/1,000. Of these, 53% have been whites, 40% blacks, 5.6% hispanic, and 1.4% others. WR stages at diagnosis were: WR-1; 68%, WR-2; 15%, WR-3; 6%, WR-4; 2%, WR-5; 4%, and WR-6; 6%. As of October 1988 there were 845 HIV cases in the USAF cohort (includes dependents and retirees), of these a total of 94 (11%) have developed CDC AIDS. Including non-AD beneficiaries, 443/790 (56%) of patients have had at least 1 yearly re-evaluation with 168 (38%) progressing to a higher WR stage. Discounting progression from WR-1 to WR-2, the rate of significant progression is approximately 15% per year. Significant progression is non-linear, and is increased for patients with higher initial WR stages.
CONCLUSION: The USAF HIV cohort is a well defined population in whom the rate of significant progression is approximately 15% per year.

M.A.P.14

TRENDS IN NEWBORN HIV RATES REVEAL THE TRUE PROPORTION SEEN CLINICALLY

Hofenson, Lynne M., Hoff, R., and Grady, G.F.
Massachusetts Public Health Center for Disease Control, Boston, MA, USA

Objective: To compare the number of HIV positive children under clinical care to the number estimated to have been born in Massachusetts.
Methods: The number of HIV positive children seen clinically, exclusive of cases from blood or derivatives, was determined by survey of pediatric infectious disease specialists, hospital discharge codes, birth and death certificates, and welfare-based reimbursement and placement data. The total number of HIV positive newborns was estimated by extrapolation back from seropositive rates known statewide for 1988 (2.5/1000) and 1987 (2.0/100), and by decremental approximations for earlier years. The statewide figures are obtained from universal anonymous screening using paper-absorbed microsamples of blood (NEJM 318:525,1988).
Results: Extrapolation back from the recently derived figures of 2.5/1000 and 2.0/1000 would approach 0/1000 in 1983. These rates, when applied to 80,000 births annually, indicate that the cumulative total of seropositives is 600. With true infection rates of 40%, there would be 240 such children and another 120 who still have ambiguous maternal antibody (60% of the 200 born in 1988). The actual numbers under follow-up for clinical or epidemiologic reasons are 80 (infected) and 50 (ambiguous HIV antibody).
Conclusion: Referral of HIV positive children based on clinical and epidemiologic factors can be evaluated for completeness by comparison to seroprevalence surveys in newborns. In Massachusetts, the proportion referred is estimated to be approximately 1/3.

M.A.P.15

A PROSPECTIVE SERO-EPIDEMIOLOGICAL STUDY OF HIV IN 30625 PREGNANT WOMEN SCREENED IN THE PARIS METROPOLITAN AREA BETWEEN FEB. 1987 AND JULY 1988.

A. Goudeau, Y. Brossard, M. Larsen, J. Huchet, F. Barin, R. Henri, et al., Paris-Tours Cooperative Study Group on Perinatal HIV Infection, CHRU Bretonneau, Tours, France.

PARIS-TOURS Cooperative study group on perinatal HIV infection.
OBJECTIVES : Prevalence of HIV infection in child-bearing women was studied in nine public hospitals and correlated to demographic data and risk factors in order to define a strategy for a nation-wide screening program for reducing perinatal tansmission of HIV.
METHODS : HIV antibody testing was systematically proposed together with an anonymous auto-sealing questionnaire asking for risk factors. Coded questionnaires were daily collected via a telematic network. HIV testing was performed by ELISA and confirmation by W.B. Seropositive women were interwied to precise their mode of infection and assess the validity of the auto-questionnaire.
RESULTS AND CONCLUSIONS : a) Systematic screening was generally well accepted : rate of refusal was 1% for on-going pregnancies and 9% for women seeking abortion. b) 218 women were HIV1 seropositive ; overall prevalence was calculated to be 0.7% and remained unchanged throughout the survey. 5 women were HIV2 seropositive. c) Rate of women who had been screened prior to pregnancy increased during the study period reaching 30% during the third semester. Accordingly, discovery of new cases decreased from 0.2 to 0.05% amongst ongoing pregnancies. d) For HIV1, major route of transmission was drug addition (70% of cases). Heterosexual transmission through random partners remained a rare event and accounted for less than 5% of cases. 4 HIV2 positive cases were women from West-Africa and one had a partner with multiple sexual contacts with Africans. e) Self-reporting of risk factors might work rather well as the basis for an accepted HIV screening if tact and confidentiallity are preserved and as long as well characterized risk factors still account for most of HIV infections.

M.A.P.16

SENTINEL HOSPITAL SURVEILLANCE FOR HIV-1 ANTIBODY VERSUS CLINICAL LABORATORY SUBMISSIONS IN A UNIVERSITY HOSPITAL

Lombardo, Joseph*; Kloser, P*; Pawel, B*; Trost, R*; Kapila, R* and St. Louis, M**.
*UMDNJ-New Jersey Medical School and University Hospital, Newark, N.J., U.S.A.
**Centers for Disease Control, Atlanta, Ga, U.S.A.

Objective. To compare the results of enzyme immunoassay (EIA) for HIV-1 antibody (HIV-1AB) in specimens which fulfill the Centers for Disease Control (CDC) Sentinel Hospital Surveillance System (SHSS) criteria versus specimens derived from a clinical laboratory (CL).
Methods. The CDC initiated the SHSS in part, to evaluate the distribution of HIV infection in the metropolitan USA. By the use of strict clinical eligibility criteria, patients who have HIV-associated disease or whose medical condition is associated with increased risk of HIV infection are excluded. Discarded blood specimens are labelled with age, sex, service, and race, then blinded prior to testing for HIV-1AB by EIA. In contrast, the CL specimens are from patients clinically suspect for HIV-1 infection. CL EIA reactive specimens were confirmed by Western blot.
Results. During the initial 3-month period at University Hospital, 7.9% of 862 SHSS specimens were repeatedly reactive by HIV-1AB EIA. The male to female ratio for reactives was 3:1 with the highest percentage of reactives in the 25-44 year olds. In contrast, of 2,174 specimens submitted to the clinical laboratory over a 15-month interval, 33.1% were confirmed positives.
Conclusion. These early data suggest a disturbingly high prevalence of HIV infection in this population from which persons with illnesses suggestive of HIV infection or associated with risk factors for HIV infection had been excluded. These findings suggest a critical need for AIDS prevention activities in impoverished inner city communities.

M.A.P.17

EPIDEMIOLOGY OF HIV INFECTION AMONG YOUNG ADULTS IN THE US: REGIONAL VARIATIONS AND TRENDS

Sharp,Erica*; Cowan,D.**; Goldenbaum,M.**; Brundage,J.**; McNeil,J.** and the Walter Reed Retrovirus Research Group.
*Henry M. Jackson Foundation,**Walter Reed Army Institute of Research, Washington, DC, USA

Objective. Since the HIV infection epidemic is evolving, we analyzed data to assess regional variation of, and trends in, seroprevalence among young adults in the U.S.
Methods: Data from routine HIV_Ab screening among male applicants for military service (very young adults) and male members of the US Army Reserve components (older adults) were analyzed to determine demographic correlates of infection risk in different regions of the U.S. Region-specific estimates were then compared with regional data from AIDS case surveillance.
Results. Regional seroprevalences per 1000 varied by region (table). Multivariate analysis controlling for age, marital status, and residence in or outside of AIDS endemic urban areas resulted in adjusted relative odds of seropositivity (Black vs. White) as follows:

Region	Crude Seroprevalence		Adjusted Relative Odds		
	Applicants	Reserves	Applicants	Reserves	AIDS Cases
Northeast	2.3	2.6	7.2	10.3	6.6
Northcentral	0.8	0.8	8.8	8.4	3.2
South	1.5	1.6	4.3	5.6	2.0
West	1.5	1.2	5.4	5.5	1.6

Conclusion. Data from seroprevalence surveillances suggest that the current HIV infection epidemic disproportionately affects young adult members of racial minorities. The relative excess among Black young adults is most significant in the Northeast and Northcentral regions. Based on these data, the impact of the infection epidemic on minority communities is more extreme than suggested by AIDS data.

SEROEPIDEMIOLOGICAL SURVEY OF AIDS,HEPATITIS AND SYPHILIS IN PORTUGUESE PRISONERS

Meliço-Silvestre, António*;Pombo,V.*;Pereira,A.*;Lopes,H.**; Côrte-Real,R.*; et al.
Infectious Diseases Clinic* and Immunohemotherapy unit** of the University Hospital of Coimbra.3049 Coimbra Codex. Portugal.

The arrested population is considered an high risk group in what concerns to transmissible infections,not only by their practices prior to internment in prisonal stablishements (we can't forget that this group comes from promiscuous environment,in wich prostitution,homosexuality and use of drugs are common) but also if we think about life in prison,where sociability is covered by particular aspects.There are about 8000 prisoners in Portugal (7500 men and 500 women) interned in 37 prisonal stablishements spreaded by the Continent and Autonomal Regions.It was in this population that we colected serum samples to detect:HBsAg,Anti-HBs (ELISA);Anti-HIV1 and Anti-HIV2 (confirmed by ELISA+W.BLOT) and VDRL.We also holded an inquiry covering epidemiological aspects that was answered by the recludes.We tested until now 7699 serum samples belonging to 446 ♀ and 7253 ♂.The median age was 30.55±10.23 ranging from 16 to 78 years old with a clear prevalence of the 20 to 30 age group.VDRL was positive in 174 (2.26%);16 ♀ (3.58%) and 158 ♂ (2.17%).HBsAg was positive in 291 (3.77%);15 ♀ (3.36%) and 276 ♂ (3.80%). Anti-HBs was positive in 1842 (23.92%), 105 ♀ (23.54%) and 1737 ♂ (23.94%). Anti-HIV1 was positive in 31 (0.40%),4 ♀ (0.89%) and 27 ♂ (0.37%).In 2 cases we found simultaneous positivity for anti-HIV1 and anti-HIV2 (only tested in 3430).The AA correlated those results with epidemiological data.

M.A.P.19

HIV 1 ET HIV 2 EN MILIEU CARCERAL A DAKAR (SENEGAL)

Samb, N.D.*, Boye, C.S.*, Diouf, G.*, Siby, T.*, Sow, A.* M'Boup, Souleymane.*
*Université de Dakar, Sénégal.

Objectifs. Evaluer la situation de HIV1 et HIV2 dans les prisons de Dakar et obtenir des informations en vue de décision de Santé Publique concernant les individus incarcérés.
Methodes. Entre Avril et Mai 1988, 1354 prélèvements de sang ont été effectués sur 1241 prisonniers (1155 hommes et 86 femmes) et 113 agents de l'administration pénitentiaire qui ont servi de population témoin. Tous les sérums ont été passés en HIV1 ELISA (Abbott) et les positifs confirmés par Western Blot sur HIV-1 et HIV-2.
Resultats Aucun des agents de l'administration pénitentiaire n'était séropositif. Par contre 11 prisonniers étaient séropositifs (7 en HIV2 et 4 en HIV1) soit une prévalence de 0,9%. Parmi les femmes la prévalence d'infection était de 2,3% pour HIV2 et de 3,5% pour HIV1. Parmi les hommes les prévalences d'infection étaient respectivement 0,4% et 0,1%, semblable à la prévalence observée dans la population générale. Tous les sujets seropositifs étaient d'origine africaine agés de 25 à 31 ans et avaient une sérologie positive pour la syphillis. De plus 7 d'entre eux avaient des antécédents d'autres MST.
Conclusion. Le milieu carcéral est considéré comme favorisant des activités à haut risque, telles que l'utilisation de drogue par IV et la pratique de l'homosexualité pouvant propager le HIV. Contrastant avec les résultats obtenus précédement en milieu carcéral dans d'autres pays d'Afrique, la prévalence d'infection par HIV parmi les hommes incarcérés était identique à celle observée dans la population générale. Cette information est d'importance pour les responsables de la Santé Publique car du fait des ressources limitées, les campagnes d'éducation et de prévention en milieu carcéral, à l'heure actuelle, devrait se concentrer sur les groupes à risque (femmes).

M.A.P.20

ARRIVE: AIDS PREVENTION TRAINING FOR INTRAVENOUS DRUG USERS PAROLED FROM PRISON

Wexler, Harry K*; Magura, S.*; Josepher, H*; Bixler R*; Beardsley, M.*; et al.
*Narcotic and Drug Research, Inc., New York, New York. U.S.A.

Objective: To develop, implement and evaluate the outcomes of the first AIDS prevention training program for intravenous drug users paroled from prison. The primary goals are to prevent relapse to IV drug use and associated AIDS risk behaviors, and to help clients become productively reintegrated into the community.
Methods: ARRIVE is based on social learning, self-help and therapeutic community principles. The program model involves training at-risk parolees for entry-level jobs in the AIDS prevention field, e.g., outreach work, peer counseling. The process of learning to help others to solve their problems is an effective means of internalizing constructive attitudes and behaviors. The ARRIVE program consists of an 8-week, 48-hour, 24-session small group curriculum. The major behavioral themes addressed are: general AIDS facts; needles; condoms; HIV-ab testing; relapse prevention; outreach presentations; and job readiness.
Results: A 24-session AIDS Prevention Training Manual has been written and tested with clients during 2 group cycles. The Manual is tailored for use with offender populations with IV drug use histories. An evaluation is in progress that will compare 6-month behavioral outcomes for parolees who participated in ARRIVE vs. a matched sample of non-participants.
Conclusion: At least 25% of U.S. prison inmates have IV drug use histories and are susceptible to relapse at release. ARRIVE is developing a strategy for reducing HIV risks within this difficult-to-treat, relatively neglected population.

M.A.P.21

OCURRENCE OF SEROLOGICAL MARKERS OF DIFFERENT INFECTIONS IN HIV SEROPOSITIVE AND SERONEGATIVE INMATES FROM A PENITENTIARY POPULATION.

Ortiz de Lejarazu R., Eiros JM, Perlado E, Orduña A, Bratos MA., R-Torres A. University Hospital and Faculty of Medicine. Valladolid. Spain.

OBJETIVE: To describe the presence of markers against different infections versus HIV serological status and behaviours in a penitentiary population.
METHODS: Sera from 323 inmates previously screened for HIV Ab by EIA and WB test and from 78 blood donors as control group were tested for HBcAb, VHDAb, HBsAg, HBeAg (by EIA test) and Ab against HSV, CMV, EBV (CF test) and T.pallidum (VDRL and FTA-abs).
RESULTS: The global prevalence of markers was as follows: 26% of inmates were HIV positives; 50.8% had VHB markers (42.8% HBcAb, 1.9% HBsAg, 6.8% HBcAb+HbsAg, 1.6% HBeAg); 40.7% of inmates HBsAg had VHDAb; 86.6% had Ab against HSV, 50.6% for CMV, and 20.9 for EBV; and 10% by FTA-abs. We found significant higher rates of VHB infection markers in HIV seropositive inmates (81.7% versus 36.5%) and also against T. pallidum (13.4% versus 4.1%). In the control group we found 2.6% of HBcAb and none for T. pallidum. We did not found any difference in the occurrence and titers of HSV, CMV and EBV Ab between HIV seropositive and seronegative inmates and the control group.The greatest prevalence of VHB and siphilis markers was found among IVDA with homo/bisexual behaviour. This results shows the high frecuency of infections that may facilitate transmission of HIV in the penitentiary population and could act as co-factors in the progresion of the disease.

M.A.P.22

HIV SEROPREVALENCE AND THE EFFICACY OF VOLUNTARY HIV TESTING AMONG MALE PRISON INMATES IN WISCONSIN

Davis, J.P.*; Vergeront, J.M.*; Frisby, H.F.*; Hoxie, N.J.*; Golubjatnikov, R.**; Pfister, J.**.
* Wisconsin Division of Health, Madison, Wisconsin, USA, ** Wisconsin State Laboratory of Hygiene, Madison, Wisconsin, USA.

Objective: To estimate the HIV seroprevalence among newly incarcerated male inmates (NIMI) and to assess the efficacy of voluntary HIV testing.
Methods: In Wisconsin, blood serum is obtained from all NIMI for hepatitis B tests; residual sera are stored at -20 degrees C. Since January 1, 1987, NIMI have routinely received HIV-related counseling and have been offered voluntary HIV antibody testing. Sera tested fo: HIV antibody included: a random sample representing 50% of all NIMI admitted 1/1/86-9/29/86 (n=997: all tested blindly), a 100% sample of NIMI admitted 1/2/87-8/31/87 (n=1689: 42% tested voluntarily, 58% blindly), and a 100% sample of NIMI admitted 1/1/88-8/31/88 (n=1651: 75% tested voluntarily, 25% blindly).
Results: In 1986, 3(0.30%) of 997 NIMI tested were HIV+ (ELISA+, Western blot+). In 1987, 9(0.53%) of 1689 were HIV+; 6(0.85%) of 708 voluntarily tested were HIV+, compared to 3(0.31%) of 981 tested blindly (OR=2.79:95% CI 0.59-17.27). In 1988, 6(0.51%) of 1187 NIMI tested voluntarily were HIV+.
Conclusion: From 1986 to 1987, there was a non-significant increase in the HIV seroprevalence among NIMI (OR=1.77:95% CI 0.44-10.22). While the difference in seroprevalence in 1987 between NIMI tested voluntarily and those tested blindly is not significant, voluntary testing detected 67% of all HIV seropositives. In 1988, 71% of NIMI consented to voluntary testing. In regions of lower HIV prevalence, routine HIV counseling with voluntary testing can be a successful strategy for screening male prison inmates.

M.A.P.23

RISK FACTORS ASSOCIATED WITH HIV INFECTION AMONG WOMEN INCARCERATED IN A MEDIUM SECURITY PRISON

Hankins, Catherine*, Gendron, S.*, St-Pierre S.*, Richard, C.**, O'Shaughnessy, M.***, Benoit, M.*
*DSC-Hôpital général de Montréal & McGill University, **CLSC Ahuntsic, Montréal, ***Federal Center for AIDS, Ottawa. Canada

Objective: To determine the relative contributions of needle use practices and unprotected intercourse to HIV seropositivity among female inmates.
Methods: Freely given, informed consent is provided for an individual nurse-administered risk factor questionnaire and tests for HIV, Hepatitis B and HTLV-I. Prisoners and guards are unaware of which prisoners consent to testing. Random code numbers are used. Results are available to consenting participants but not to health service nor prison authorities.
Results: To date 107/217 (49.3%) are injection drug users (IDU). Overall 13 (6%) seropositives (SP) have been detected. All are IDU for a rate among IDU of 12.2%. 11 (84.6%) report needle sharing. Of 60 current prostitutes, 9 (15%) are seropositive. Comparing SP to the total study population no significant differences were found for oral contraceptive use, hx. of anal intercourse. A striking 27.4% of the total study population (vs 30.8% of SP) have had sex since 1979 with a man who has had sex with another man. SP are more likely to be engaged in prostitution (69.2 vs 27.6%), to have used condoms with casual partners (90.9 vs 58%) in the last 12 months, to have had an IDU partner since 1979 (92.3 vs 48.8%), and to have had herpes (23.1 vs 6%) or genital warts (30.8 vs 18.9%).
Conclusion: Recruitment and detailed analysis are ongoing to determine to what extent needle use versus sexual practices explain seropositivity.

M.A.P.24

FREQUENTATION HOSPITALIERE ET INFECTION PAR LE VIH EN MILIEU CARCERAL

BOUCHARD Isabelle*, ESPINOZA P.*, STEIN S.*, POLO DEVOTO J.**, D'HAVILLIVILLEE P.*, BENAMOUZIG R.**
* Hopital de Fresnes(EHPNF) Allée des Thuyas 94261 FRESNES CEDEX FRANCE
** A.P.S.P.

OBJECTIFS : Décrire les caractéristiques sociales, cliniques et biologiques des malades séropositifs pour le VIH admis à l'hopital de Fresnes de 1985 à 88
METHODES : Etude rétrospective sur les malades hospitalisés de 1985 à 1988 ayant eu une sérologie VIH . Cette étude a déterminé parmi les séropositifs, l'âge des patients, le sexe, le mode de contamination, le motif d'hospitalisation, le stade de l'infection VIH (classification du CDC), le taux des CD4 la présence de l'antigène VIH.
RESULTATS : En 1985, 180 sérologies ont été prescrites. De 85 à 87, 40 cas de SIDA ont été recensés. En 87 140 (3,8%) sur 3669 malades ont été hospitalisés, 905 sérologies prescrites, 326 (9,4%) étaient positives. Parmi ces 326 patients séropositifs, 85% sont des hommes d'âge moyen de 27 ans. 91% sont des toxicomanes par voie parentérale. 3,5% originaires de pays d'endémie, 2% homosexuels, 2% contaminés par voie hétérosexuelle, 1,5% par transfusion sanguine. 32% ont été hospitalisés pour bilan de l'infection VIH. 21% ont des taux de CD4 < 200mm³. 11% ont une antigénémie VIH positive. 56% sont des stades II, 32% des stades III, 11% des stade IV.
CONCLUSION : L'accroissement du taux de séropositifs dépistés de 85 à 88 et l'évolution du nombre de SIDA justifient au sein de l'hopital pénitentiaire l'adaptation des moyens hospitaliers.

M.A.P.25

EPIDEMIOLOGIE DU SIDA EN MILIEU CARCERAL

ESPINOZA pierre, BOUCHARD I., POLO DEVOTO J, ATKHEN P.
Hopital de Fresnes (EHPNF) Allée des Thuyas 94261 FRESNES FRANCE

INTRODUCTION Les taux de séropositivité en prison sont élevés (6%), soit 20 à 30 fois plus que dans la population générale. L'hopital pénitentiaire (EHPNF) accueille principalement des malades de la région parisienne (3500/an). L'analyse des cas de SIDA hospitalisés est utile compte tenu des prévisions.
OBJECTIFS - METHODES : L'étude rétrospective des dossiers de SIDA correspondant à la définition du CDC d'Atlanta comprend l'analyse des caractéristiques sociales, modes de transmission, les manifestations cliniques, la situation pénale (détention préventive, condamnés), le résultat des procédures de libération, la fréquence des hospitalisations pour complication, évolution.
RESULTATS : De juin 85 au 31.12.87 nous avons recensé 40 cas de SIDA et 35 en 88. Les résultats préliminaires montrent : - Groupe de transmission toxicomanie IV : 85%, africains 6%, partenaire sexuel d'une toxicomane 4%, homosexualité 2%, post-transfusionnel 2%. -Manifestations cliniques parfois associées : PCP prouvée au lavage 27%, tuberculose 27%, candidose oesophagienne 13%, toxoplasmose cérébrale 13%, candidose pulmonaire 4%, cryptosporidiose 2%, encéphalite à VIH 2%, pneumopathie CMV 2%, mycobactérie atypique disséminée 2%, Sarcome de Kaposi 7%. - Biologiquement le taux moyen de T4 était de 152/mm³, présence de l'antigène VIH1 dans 70% des cas testés. Le diagnostic est posé à l'hopital de Fresnes, en milieu pénitentiaire dans 50% des cas, lors du transfert dans un hopital civil dans les autres cas. Dans 52% des cas la séropositivité est découverte en même temps que le SIDA. L'analyse des processus de libération, de la fréquence hospitalière permet d'identifier des préoccupations pour l'avenir en milieu carcéral.

M.A.P.27

INCREASING TUBERCULOSIS IN ASSOCIATION WITH AIDS/HIV AMONG NEW YORK STATE PRISON INMATES

Morse, Dale*; Truman, B.*; Braun, M.*; DiFerdinando, G.*; Maguire, B.**; Broaddus, R.**
*New York State Department of Health, Albany, New York, USA
**New York State Department of Correctional Services, Albany, New York, USA

Objective. To describe the epidemiologic features of the inmate TB cases in association with HIV/AIDS.
Methods. We established a registry of all 230 inmates developing TB in state correctional facilities from 1976-1988 to allow analysis of epidemiologic data (including demographic, disease and HIV/AIDS information).
Results. The incidence of tuberculosis among inmates in NYS correctional facilities has increased dramatically from 15 per 100,000 in 1976-78 to > 130 per 100,000 in 1988. This increase has closely paralleled the increasing incidence of AIDS among inmates (from 8.4 per 100,000 in 1981 to > 500 per 100,000 in 1988). Recent TB cases have had similar characteristics as AIDS cases, occurring primarily among males, aged 30-49 years, from minority populations who have had histories of drug use. Extrapulmonary tuberculosis, common in HIV infection, has been found in 36% of the 1984-88 TB cases. Sixty-three percent of TB cases in the past 4 years have had AIDS or HIV infection; none were known to be HIV seronegative.
Conclusion. The increasing incidence of tuberculosis among prison inmates in association with AIDS and HIV infection, will require enhanced TB control efforts within prison and in communities from which inmates originate.

M.A.P.26

UPDATED TEMPORAL TRENDS OF HIV-1 INFECTION AMONG INMATES ENTERING MARYLAND PRISONS (U.S.A.) 1985-1988.

Vlahov David, Munoz A, Taylor C, Taylor E, Brewer F, Polk BF. The Johns Hopkins School of Hygiene and Public Health, Baltimore, MD, USA.

Objective To monitor temporal trends of HIV-1 infection among inmates entering Maryland state prisons, and to investigate whether the strength of association between HIV-1 and select demographic factors varied over time.
Methods Excess sera and demographic data were obtained from samples of consecutive inmates entering during the same months over four years. Sepcimens were assayed using ELISA and Western blot techniques. Logistic regression methods were used for multivariate analysis.

Results Year:		1985	1986	1987	1988
N	:	886	756	1486	1386
% HIV-1	:	7.1%	7.7%	7.0%	8.4%
Odds Ratios from final multivariate model:					
> 25 years	:	2.8	3.7	4.6	5.2
Minority	:	4.7	4.6	8.0	9.8
Urban	:	6.2	2.6	2.0	5.5

Evaluation of effect modification by year were all not significant.
Conclusion These data suggest that prevalence and risk groups have remained stable over four years.

M.A.P.28

INCIDENCE AND PREVALENCE OF HIV INFECTION DURING 44 MONTHS OF TESTING PROSTITUTES/IVDU'S IN THE WOMEN'S JAIL, ORANGE COUNTY, CALIFORNIA

Prendergast, T.J., Jr.*; Maxwell, R.*; Greenwood, J.R.*; Burrell, Peter*; Swatzel, C.*.
*County of Orange Health Care Agency, Santa Ana, California, U.S.A.

OBJECTIVE: To assess the prevalence and monitor the incidence of HIV infection in sexually active female prostitutes and IV drug users --- a group associated with previous sexually transmitted diseases.
METHODS: Women booked at the Orange County Women's Jail between March, 1985 and November, 1988 were offered an opportunity to obtain a confidential HIV test, if their charge suggested prostitution, IV drug use or drug use-related activity. Laboratory testing utilized ELISA testing (initial) with confirmation using Western Blot or IFA.
RESULTS: A total of 3,014 tests were completed on 1,781 individuals. There were 458 individuals tested on multiple occasions during this time. At the conclusion of testing, 53 individuals with positive results had been identified (ratio of 1.8 positives/100 tests equal to 3.0% of all persons tested). Of those tested multiple times (additional tests were offered only to those with negative tests), a total of 16 individuals converted from negative to positive during the period of follow-up. The rate of positivity per 100 person-years of observation was 2.6 for the entire period.
CONCLUSION: Voluntary, confidential testing in the County Jail provided an estimation of prevalence and incidence of HIV infection in a high risk group of women of great public health concern.

M.A.P.29

FREQUENCY OF HIV SEROCONVERSION AMONG BLOOD DONORS: RELATIONSHIP TO RISK OF HIV TRANSMISSION

Nardolillo, J.; Dodd, Roger. American Red Cross, Biomedical Research & Development, Rockville, MD, USA.

Objective To estimate HIV seroconversion and infectivity rates among donors.
Methods. During the period 4/85–9/88, 27 blood centers reported data on 7,675,087 HIV tests identifying 1122 seropositive donors. A seroconverter is a donor who had an HIV(-) donation followed by an HIV(+) donation.
Results. 118 seroconverters were identified, with a range of 1.8 months to 35.8 months between the first HIV(+) donation and the prior donation. The group overall is 81% male, but the sex distribution has changed slightly over time, with no female seroconverters in 1985, increasing to 23% in 1988.

These donors are potentially able to spread HIV infection through their initial HIV(-) donation. The actual number of seroconverters has remained stable over time, but seroconverters in 1985 represented only 3% of all WB+ donors, increasing to 11% in 1986, 14% in 1987, and 21% in the first nine months of 1988. Although this proportion is steadily increasing, the fraction of donors who had a seronegative donation six months or less before their positive donation has decreased over time. In 1985, 78% of seroconverters had a previous HIV(-) donation less than six months prior to their HIV(+) donation, with 39% in 1986, 24% in 1987, and only 17% in the first nine months of 1988. Thus the projected infectivity rate for these donors has decreased from 1 in 200,000 in 1985 to 1 in 240,000 in 1988.
Conclusion. Although the percentage of seroconverters in relation to all WB+ donors has increased over time, there is a definite decrease in the number of donors who have seroconverted within a six month period, thus slightly lowering the projected infectivity rate of HIV seronegative donations.

M.A.P.30

BLOOD CENTER/HEALTH DEPARTMENT COLLABORATION: A METHOD FOR DETECTING INFECTED PREVIOUS DONORS.

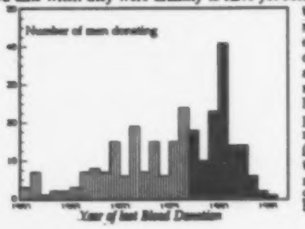
Samson, Susan*; Busch, M*; Holland, P**; Ward, J***; Garner, J*; Perkins, H*.
*Irwin Memorial Blood Centers (IMBC), San Francisco; **Sacramento Medical Foundation Blood Center (SMFBC), Sacramento, California; ***Centers for Disease Control (CDC), Atlanta, Georgia; and collaborating Health Departments, USA.

Objective. To compare the relative yield of infected previous donors identified from AIDS case listings obtained from local versus distal regional health departments.
Methods. The listings of reported AIDS cases obtained from 2 local, 4 contiguous, and 2 distal counties were compared with IMBC donor files. The listings of reported AIDS cases obtained from one distal site was also cross referenced with their own donor base (SMFBC).
Results. Overall 317/7973 (4%) of reported AIDS cases were matched as previous IMBC donors. The match rates varied among localities: the match rate for local counties (4.3%) was significantly greater than for contiguous (3.6%) and distal (1.7%) localities (p = .14 and p = .001, respectively). The rate of infected donors detected when a distal site (SFMBC) cross referenced their local AIDS list with their own donor base was however, 7.5% (11/147).
Conclusion. The data demonstrate the utility of regularly comparing donor files with local AIDS listings in both low and high AIDS prevalence areas in order to expedite detection of infected recipients. A significant number of infected former donors may be identified from the listings of health departments adjacent to the area of operation of a regional blood center. This approach warrants national implementation.

M.A.P.31 BLOOD DONATION BY INDIVIDUALS WHO LATER DEVELOP AIDS

Feigal, David W.*; Hollander,H**; Ziegler, J***; Clement, M*; Volberding, PA*;
Medical Services of * San Francisco General Hospital; ** University of California, SF; *** Ft. Miley VA Hospital; UCSF, San Francisco, CA, U.S.A.

Objective: To determine the past blood donations by individuals who later develop AIDS.
Methods: The UCSF AIDS Registry has collected detailed medical histories since 1985 from 2605 individuals, 992 of whom had had *Pneumocystis carinii* pneumonia, Kaposi's sarcoma, or cryptococcosis at the time of initial evaluation. Patients are asked the date that they last donated blood. It is not known if the blood was discarded after blood bank screening.
Results: 292 patients (29%) had donated blood. 162 patients had not donated blood since 1976, a time when they were unlikely to have yet been HIV infected. The peak year for last donation was 1980 (n=41) and only 4 individuals reported donating blood after 1983. Of these: one patient donated blood 17 months before developing Kaposi's sarcoma; two others 21 and 22 months before PCP; one patient reported donating blood one month after PCP. Of the 992 with AIDS only one other patient reported donating blood after PCP (14 months).
Conclusions: In the era before HIV Antibody testing, blood was donated by 13% of gay men after they were likely HIV infected. Some of this blood was probably discarded. By 1985 donation had ceased.



M.A.P.32 SURVEILLANCE FOR UNUSUAL MODES OF HIV TRANSMISSION IN THE USA — A 5-YEAR MULTICENTER STUDY OF BLOOD DONORS

Petersen, Lyle* and the HIV Blood Donor Study Group**.
*Centers for Disease Control, Atlanta, Georgia, USA; **Investigators from 20 Blood Donation Sites throughout the USA

Objective. To monitor levels, trends, and modes of HIV infection in blood donors—the largest, low-risk population screened for HIV. Because persons with HIV risk are excluded, infection by uncommon means (eg, from a heterosexual partner without recognized risk) is relatively easily detectable.
Methods. Seropositive donors at 20 blood centers (approximately 2,000,000 donors/yr) are interviewed using a standardized questionnaire; denominators for seroprevalence rates are determined from blood center records.
Results. Since June 1988, 147 seropositive donors have been interviewed. Risk factors for the 114 males were homo/bisexuality (52%), intravenous drug use (IVDU)(9%), previous blood transfusion (BT)(4%), and sexual partner of a person at risk (SPPR)(13%). Risk factors for the 33 females were IVDU (9%), BT (9%), and SPPR (61%). 23% of males and 21% of females had no identified risk (NIR). Demographic characteristics of NIRs were similar to those with identified risk. Using National American Red Cross HIV seroprevalence in first-time donors from 6/87-5/88 (0.057% for males and 0.010% for females), and applying the observed rate of NIRs in this study, we calculated that a maximum of 1 in 7,661 male and 1 in 47,170 female donors had been infected by unidentified means, such as from sexual partners with unrecognized risk.
Conclusion. Most seropositive donors have traditional HIV risk factors, suggesting that heterosexual transmission from partners of unrecognized risk or other possible transmission modes are uncommon. Many NIRs in this study may not have acknowledged HIV risk factors.

M.A.P.33 SEROPOSITIVITE HIV CHEZ LES DONNEURS DE SANG ET ESTIMATION DU RISQUE RESIDUEL EN TRANSFUSION

Couroucé, Anne-Marie et le Groupe de travail Rétrovirus de la Société Nationale de Transfusion Sanguine - Paris France

Objectif : Comparer la prévalence des donneurs confirmés anti-HIV positif entre 1985 et 1988 et évaluer le risque résiduel de transmission du virus par transfusion
Méthode : Les 10 centres de Transfusion (CT) du groupe de travail représentant environ le 1/4 de l'activité de collecte des CT français ont rassemblé leurs résultats en individualisant les nouveaux donneurs (ND) et les donneurs réguliers (DR).
Résultats : 1) Prévalence des dons anti-HIV positifs

	Nbre dons testés	Total (0/00)	ND:Nbre (0/00)	DR:Nbre
1985 (6mois)	510 493	318 (0.62)	181 (2.4)	137
1986	1126 278	479 (0.42)	283 (1.7)	196
1987	1131 316	361 (0.32)	269 (1.5)	92
1988	1065 532	176 (0.16)	128 (0.8)	48

2) Estimation du risque résiduel : Base du calcul = 25 % des dons antiHIV négatif provenant de donneurs dépistés séropositifs dans un délai maximum de 1 an sont infectieux (Jullien, Lancet 1988 ii 1248)

	Intervalle entre dons négatif et positif				Estimation du
	< 2 mois	2 à 4 mois	4 mois à 1 an	> 1 an	risque par don
1987	2	12	49	29	1 pour 72000
1988	3	4	38	5	1 pour 100000

Conclusion : Entre 1985 et 1988, la séropositivité HIV chez les donneurs de sang a diminué de 4 fois, cette baisse ayant porté à la fois sur les nouveaux et les anciens donneurs. Le risque résiduel transfusionnel diminue parallèlement et est estimé à 1 pour 100.000 dons en 1988.

M.A.P.34 THE RISK OF HIV-1 TRANSMISSION BY TRANSFUSION OF SCREENED BLOOD

N. Cohen**, A. Munoz*, Ken Nelson*, O. Frazier***, D. Yawn****, B. F. Polk*, et al.
*Johns Hopkins Medical Institutions, Baltimore, MD; **Texas A & M University, College Station, TX; ***St. Luke's Episcopal Hospital, Houston, TX; ****The Methodist Hospital, Houston, TX U.S.A.

Objective: This prospective study will determine the risk of seroconversion to HIV-1 in a cohort receiving multiple transfusions of blood or blood components screened for antibody to HIV-1.
Methods: The study will require fifty-four months to enroll and follow-up approximately 13,000 cardiac surgery patients. Based on current blood product utilization at the three study centers, an estimated 101,000 transfusion exposures will be observed. The probability of HIV-1 transmission will be estimated and the upper bound of the 95% confidence limit will be calculated using the binomial distribution.
Results: To date, serum samples from 3,117 persons representing 29,495 transfusions exposures have been tested. One seroconvertor has been identified; our estimate of the risk of HIV-1 transmission by transfusion is 0.003% per screened unit with a 95% upper bound equal to 0.016% per unit.
Conclusions: The interim results of this ongoing study provide valuable information to clinicians and the blood banking community regarding the effectiveness of HIV-1 screening and permit public health officials to make statements with greater confidence about the risk of HIV-1 transmission by screened blood.

M.A.P.35 THE EPIDEMIOLOGY OF TRANSFUSION-ASSOCIATED (TA) AIDS IN CHILDREN IN THE UNITED STATES, 1981 TO 1988

Jones, Donna; Byers, R; Bush, T; Rogers, M
Centers for Disease Control (CDC), Atlanta, Georgia. U.S.A.

Objective. To describe the demographic and clinical characteristics of pediatric TA AIDS.
Methods. AIDS cases reported to CDC from 1981 to December 1988 were reviewed. Pediatric TA and perinatally acquired (PA) AIDS cases were compared.
Results. Through 1988, 169 children with TA AIDS were reported to the CDC (13% of the 1346 pediatric AIDS cases). The percent of pediatric AIDS cases attributable to TA infection varied by region from 4% in New York City to 30% in Los Angeles. From 1983 to 1987, the yearly incidence of diagnosed cases of pediatric TA AIDS increased from 40 to 42 cases (5%), while PA cases increased from 147 to 301 (107%). The median age at transfusion in pediatric cases was one month (range, birth to 11 years). The median age at diagnosis was 49 months in pediatric TA AIDS cases and 11 months in PA cases. Pediatric TA AIDS cases are more likely to be male (62%) compared to PA cases (50%). The cumulative incidence of pediatric TA AIDS was 2.4 times higher in blacks and Hispanics than in whites (95% C.I., 1.6-3.2), although TA AIDS cases are more likely to be white than PA cases (37% vs 15%). The observed median incubation period was longer for pediatric TA AIDS cases than for PA cases (36 mos. vs 25 mos., p=.0001). The median survival after diagnosis of pediatric TA AIDS did not differ from that of PA cases (9.3 vs 10.8 months).
Conclusion. Children with TA AIDS are distinct from PA AIDS patients. Pediatric TA AIDS cases are being diagnosed at a slower rate than PA AIDS but continue to develop. Donor screening has nearly eliminated new infections; thus this group is important in the study of incubation period in children.

M.A.P.36 SEROPREVALENCE OF HIV INFECTION AMONG BLOOD DONORS IN ROME

Rannella, Emilio; Ippolito,G.**; Miceli,M.*; Angeloni ,P.*
*Italian Red Cross, National Center for Blood Transfusion
**"Lazzaro Spallanzani" Hospital for infectious diseases-Rome-Italy

Objective.To estimate the prevalence of positive HIV antibodies in a large blood donor population in Rome (about 50% of total blood supply in Rome), to define the epidemiologic characteristics of seropositive subjects, and to determine the efficacy of voluntary self deferral program.
Methods.Since 1985 blood donations were tested routinely for HIV antibodies, donors have been interviewed by trained personnel and informative materials have been distributed to invite donor belonging to risk groups, to voluntary defer. Seventy-one seropositive subjects were contacted (86.6%).
Results.Confirmed prevalence (%.) by year and percentage distribution of risk factors of positive donors are reported in table.

Year	units	HIV+ve	prev%	homosex	IVDA	Heterosex	Unknown
1985	38323	23	.060	10.5	84.2	-	5.3
1986	50290	29	.058	16.0	44.0	40.0	
1987	47211	16	.034	12.5	62.5	25.0	
1988	45819	14	.030	9.1	36.4	45.4	9.1

Conclusions.The progressive decrease in the prevalence rate among blood donors indicates the efficacy of self-deferral program and emphasize the importance of alternative sites for test performing and the need of anonymous testing opportunities.

M.A.P.37

36 POST-TRANSFUSIONNAL (P-TRF) HIV INFECTION IN A REGIONAL CITY HOSPITAL SINCE 1980.

Quaranta,J.F.*; Cassuto-Viguier,E.**; Sanderson,F.***; Vivinus,M.*; Cassuto,J.P.***; Dellamonica,Pierre****.
* Laboratoire d'Immunologie, **Néphrologie, *** Médecine Interne, **** Maladies Infectieuses, C.H.R.U. Nice, France.

Objective. Nice (400,000 inhabitants) is characterised by a high prevalence of the HIV infection with a rate of seropositive blood donors two times more higher than in France. Blood donors are screened for HIV in our country since august 1st 1985. At the end of 1988, a P-TRF HIV infection was diagnosed in 36 patients (19 to 82 years old, 21 females).
Results. At the first examination, patients were divided 14 in II, 6 in III, 5 in IVa and 11 in IVc according to CDC groups, with low T4 cells count (301 ± 305/mm3),high serum beta-2-microglobulin level (5.7 ± 4.3 mg/l). These results related with p25 antigenemia suggested a bad prognosis which was confirmed by the outcome : 7 more AIDS occured within 24 months and 15 patients yet alive. 35 patients had a presumed date of contamination ranged between 1980 and 1985 and one after the blood donors screening. Most of the patients were transfused during surgery ($\bar{m}$ = 4.1 blood units), 4 patients in emergency, 2 for hematological diseases (30 and 128 units) and 5 hemodialysed patients (2 to 8 blood units). Only two of the investigations required to Blood Bank in search of the infected donors has resulted in a concrete proof.
Conclusion. The P-TRF HIV infection has a bad prognosis compared to others risk groups. Despite the systematic blood donors testing, the risk is low but remains; this should warrant autotransfusion policy in sheduled surgery, or more accurate screening (e.g. antigenemia or PCR).

M.A.P.38

BLOOD SALE AND DONATION BEHAVIOR OF IVDUs

Chitwood, Dale, D.*; Comerford, M.*; McCoy, C.B.*; et Trapido, E.J.*.
*University of Miami School of Medicine, Miami FL., USA.

Objective. To describe the blood selling and blood donation behavior of intravenous drug users (IVDUs) between 1978-1988.
Methods. IVDUs (703) in drug treatment in South Florida who were enrolled in a longitudinal study of HIV serostatus were asked items pertaining to the sale and donation of blood.
Results. Of the 703 IVDUs,181 (25.7%), had sold or donated blood since 1978; of these 181, 63.0% had sold and 37.0% had donated blood. There were no significant demographic (age, gender, ethnic) differences between those who donated and those who sold blood. Of the 181 IVDUs, 92 reported their last sale or donation to have occured after 1985, the year HIV screening in blood banks was inititated. Of these 92, 63 had sold blood. The seroprevalence rate among those selling or donating since 1978 was 11.6%; 7.6% of those selling or donating after 1985 were HIV+. There was no difference in seroprevalence between those who sold and those who donated blood.
Discussion. IVDUs continue to sell or donate blood in spite of attempts to persuade them not to do so. A larger percentage sell blood than donate. While it is not known if any of this blood eventually gets into the blood bank supply for human use, the donation or selling of blood by IVDUs, a high risk group for HIV infection, poses a public health threat.

M.A.P.39

IMPACT OF AN AUTO-DESIGNATION FORM ON BLOOD DONOR SELECTION.

Landry,Yves*; Hankins, C.**; Jean, B.*; Soto, J.C.***; Décary, F.*
*Canadian Red Cross, Montreal, Quebec, Canada; ** DSC, Montreal General Hospital, Montreal, Quebec, Canada; *** DSC, St-Luc Hospital, Montreal, Quebec, Canada.

OBJECTIVE: To determine if the use of an auto-designation form would differentiate between blood donors at high and at low risk.
METHODS: From February to May 1988, 21,692 donations were made at a permanent site which used an auto-designation form. Donors designated their blood for transfusion (97.7%) or laboratory purposes (1.5%) after reading a list enumerating high risk activities. Of these forms only 0.8% could not be utilised. The blood from the laboratory group (LG) was tested but not used.
RESULTS: In the transfusion group (TG) 36/21,197 (0.17%) were ELISA positive, while in the laboratory group (LG) 6/325 (1.8%) were positive. WESTERN BLOT confirmation followed for 8/36 (22.2%) in the transfusion group versus 4/6 (66/7%) in the laboratory group. WESTERN BLOT confirmed individuals in the LG were all males aged 17-29 years. The seroprevalence of HIV antibody was .038% for TG and 1.23% for LG. The specificity of our auto-designation form is 98.5%. The negative predictive value was 99.9% and the global efficiency 97.7%.
CONCLUSION: The auto-designation form appears to be a helpful additional screening method allowing to separate donors in two sub-populations, one at high risk and the other at low risk, thus preventing the utilisation of blood from high risk donors and reducing the risk of HIV transmission during the window period.

M.A.P.40

PREVALENCE OF HIV-ANTIBODIES IN BLOOD DONORS IN THE FRG

Dorothea Glück, K. Koerner, B. Kubanek, G. Caspari, G. Elbert, W. Grässmann et al.
Dept. Transfusion Medicine, University of Ulm and German Red Cross Blood Bank, Helmholtzstrasse 10, D-7900 Ulm, FRG, for the German Red Cross Blood Banks in the FRG

Objective. In a multicenter study of the German Red Cross Blood Banks prevalence and epidemiology of HIV-antibodies in blood donors are studied.
Results. From July 1985 to September 1988, 7.5 million donations given by about 1.5 million blood donors were tested for HIV-antibodies routinely and 250 were found to be positive in at least one Western blot (Wb).
Following a rather rapid decrease in 1985/86 the overall seroprevalence remains thereafter constant with rates of less than 2 per 100,000 until the end of 1988. The geographic distribution varies with the highest prevalence in urban centers and correlates well with the geographic incidence of AIDS cases.
More than 90% of the seropositive donors were homo-/bisexual men, drug abusers and heterosexual partners to known AIDS-risk persons. Age and sex distribution were comparable to the patterns in recognized AIDS patients in the FRG.
Conclusion. Our data show that in blood donors, representing one low risk segment of the general population, there is no evidence of a rapid spread of HIV infections. However, they do not imply the absence of new infections but an infection rate on a very low level. At present, we have no indication that unaware heterosexual transmission occurs frequently in blood donors. However, there is a shift to donors infected heterosexually by contact to known risk persons. This suggests a more efficient exclusion of persons with a recognized risk.

(Supported by BMFT, FKZ II-053-88)

M.A.P.41

A FOLLOW-UP STUDY OF CHILDREN OF ANTI-HIV POSITIVE HAEMOPHILIACS

Goldman, Eleanor; Lee, Christine A.; Morris-Smith, J.; Griffiths, P.D.; Trompeter, R.S. and and Kernoff, P.B.A.
Royal Free Hospital, London, England.

Objective. To monitor the progress of 10 children born to 9 anti-HIV seropositive fathers between December 1984 and May 1988.
Methods. Infants were seen soon after birth and then at yearly intervals. Their physical development was assessed with particular attention to growth. Ability and intelligence in relation to expected levels at any given age was measured using WISC/R, WPPSI and other relevant tests. Laboratory tests for anti-HIV, p24 antigen and CD4 lymphocyte count were performed at each visit. The duration of seropositivity and stage of HIV disease of the father at the time of conception was assessed retrospectively from clinical records and results of laboratory tests carried out on stored serum. The anti-HIV status of the wives was checked from 1985 onwards.
Results. Ten children were conceived by 9 seropositive, p24 antigen negative, asymptomatic haemophilic fathers. All 10 children have been anti-HIV negative since birth and have continued to develop normally. Eight wives have remained anti-HIV negative, one of them after two full term pregnancies. One wife chose termination of a second pregnancy when found to be anti-HIV positive.
Conclusion. None of the children appear to have any evidence of overt or latent HIV disease. In spite of being made aware of the risks, some anti-HIV positive haemophiliacs and their wives have chosen to have children.

M.A.P.42

HEMOPHILIACS DOUBLY INFECTED BY HIV-1 AND HTLV-I

Masafumi Akao; Yorifuji,H.; Koike,K.; Hada,M.; Ikematsu,S.; and Fujimaki,M.
Tokyo Medical College, Clinical Pathology, Shinjuku, Tokyo, Japan.

Objective. On the investigation of immune abnormalities and clinical courses of HIV-1 infected hemophiliacs, we found patients infected by both HIV-1 and HTLV-I had a more rapid fall in their immune functions than those infected singly by HIV-1. Subjects and Methods. 185 hemophiliacs are involved in this study. Anti-HIV-1 antibodies are assayed by WB and ENVACOR, and anti-HTLV-I antibodies are also assayed by ELISA, PA, IF and WB method. Immunological parameters such as lymphocyte subsets, 2 microglobulin, immunoglobulin levels and HIV-related markers are measured. Results. 107 of 185 hemophiliacs are seropositive in HIV-1(57.8%). 11 of 185 are seropositive in HTLV-I. Seven hemophiliacs are seropositive both in HIV-1 and HTLV-I. Two of 7 have been at the stage IV-C2(CDC) in 1986, and one other case has been at the stage IV-A in 1987. Another case has been with severe decompensated liver cirrhosis and the stage IV-A. Clinical features are widely varied, such like toxoplasmosis, PCP, CMV pneumonia, IDTP, VZV infection, parvovirus infection, and so on. Conclusion. We have already reported the prevalence of HIV-1 infection were not different in the existence of preceded infection of HTLV-I in Japanese hemophliac populations. But, 4 of 7 double infection cases have shown advanced symptoms in this study. These data strongly suggested preceded infection by HTLV-I might affect *in vivo* on the progress of immune dysfunctions by HIV-1 infection. Further cumulative investigations are urgent.

M.A.P.43

ANTI-HIV SEROPREVALENCE IN BLOOD DONATIONS FROM JULY 85 UNTIL DECEMBER 88 IN SWITZERLAND.

Burckhardt, Johann J.[1], Bütler-Brunner, E.[1], Perrin, L.H.[2] and Bachmann, P.[1]
[1]Central Laboratory, Blood Transfusion Service SRC, Bern; [2] Department of Medicine, University Hospital, Geneva, Switzerland

From July 1985 until December 1988, the Central Laboratory Blood Transfusion Service Swiss Red Cross collected over 1 million units of blood from non-remunerated donors. We tested these units for anti-HIV antibodies with enzyme-linked immuno assays based on viral lysates or recombinant proteins. During this time, 110* units were confirmed positive. We observed, however, a dramatic decrease of seropositive units and of the resulting seroprevalence between the 2nd half of 85 and the 2nd half of 88 (39 and 1* or 38.3 and 0.7* per hundred thousand, respectively). Furthermore, we noted a decrease in each of the following categories:

Seroprevalence (PHT)	2nd half of 85	1st half of 88	2nd half of 88
males (civilians)	14.9	3.0	*
females (civilians)	16.5	2.8	*
males (military)	68.2	15.2	*
repeat donors	18.5	3.8	*
first-time donors	71.9	0	*

74 % of the positive units were donated by 29 years old or younger donors, who provide about 65% of the blood. We found indeterminate confirmation results especially in units from females and those with increasing age. During 1988, we tested 73 units with a repeatedly reactive screening test by using the polymerase chain reaction (PCR) with DNA extracted from about 1 mega peripheral blood mononuclear cells. PCR-negative units were never serologically confirmed positive.
Based on the present seroprevalence figures and the fact that on average 1.4 units per donor per year are collected, we calculate the probability for a false negative unit to be less than 1/500,000.

* The actual figures will be included.

M.A.P.44

DIFFERENT EPIDEMIOLOGY OF HIV INFECTION IN HEMOPHILIACS (H) FROM THREE EUROPEAN COUNTRIES.

Pier Mannuccio Mannucci, A. Gringeri, A. Bianchi Bonomi Hemophilia and Thrombosis Center, University of Milan, Italy.

Italy, France and W. Germany are comparable in population (ca. 55 million) and number of H (ca. 3,000). Italy and Germany are also comparable for type of factor concentrates given to H A and B (commercial, from US plasmapheresis plasma). In France, H A use ca. 50% commercial and 50% domestic FVIII, but H B use quasi exclusively domestic FIX. The TABLE shows that at the end of 1987 there were more AIDS and anti-HIV(+) cases among German than Italian H A. Also there were more French H A anti-HIV(+) cases than in Italy, though AIDS cases were similar. For H B, cases with AIDS and anti-HIV(+) were comparable in Italy, Germany and France.

	All hemophiliacs			Hemophilia A			Hemophilia B		
	Total N.	N.AIDS cases	N.anti-HIV(+)	Total N.	N.AIDS cases	N.anti-HIV(+)	Total N.	N.AIDS cases	N.anti-HIV(+)
Germany	2476	148	1172	2152	131	1024	324	17	148
France	2455	58	1038	2067	40	903	388	18	135
Italy	2772	57	637	2459	36	476	313	20	138

The reason for differences between France/Germany vs Italy is unclear. In the early '80s, when most HIV infections occurred, German H A were treated annually with larger average FVIII amounts than Italian H (84,000 I.U/pt vs 25,000). Hence, German H A had a higher cumulative likelihood of being exposed to HIV from 1978 for 1985, when virucidal methods prevented new infections. This explanation, however, would not account for the higher prevalence of anti-HIV(+) in France, because FVIII usage was similar to that in Italy (22.000 I.U vs 25.000). Hence, there appear to be population differences in susceptibility to develop HIV infection in hemophiliacs.

M.A.P.45

HEPATITIS B AND HIV COINFECTION IN HEMOPHILIACS.

Bacharar, Paul; White, G.; McMillan, C; Lemon, S.M.
Department of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC USA

Objective. Like HIV, HBV also infects lymphocytes, alters the immune response, and has reverse transcriptase activity. The clinical significance of HBV and HIV coinfection was investigated.
Methods. Serial HBV and HIV serologies were determined in a cohort of 155 severe Factor VIII deficient hemophiliacs between 1982-1988. Lymphocyte subset analysis and clinical status were evaluated at regular intervals.
Results. By 1982 the majority of severe FVIII deficient patients demonstrated serological evidence of HBV (92%) and HIV (69%) exposure. Seven HIV infected patients reverted from anti-HBs to HBsAg positive suggesting persistence, reactivation, or reinfection of HBV in this population. A trend toward slower immune status deterioration was noted in patients with persistent HBsAg carriage.

	HIV+ HBsAg+ (n = 10)	HIV+ anti-HBs+ (n = 98)	
mean CD4+	396.8	278.0	*p=0.094 (Kruskal Wallis Chi Square)
median CD4+	465.5	259.0	
% developing AIDS	0 (0/10)	22.4 (26/116)	**p=0.09 (Chi Square)

Conclusion. HIV infection may allow HBV reactivation or reinfection which might warrant HBV vaccination of household contacts of even anti-HBs seropositive HIV infected patients. Active HBV infection perhaps by infecting lymphocytes may alter HIV induced immune deterioration.

HIV in Prostitutes and Homeless Populations

M.A.P.46

HIV SPREAD IN PROSTITUTE POPULATION IN TOULOUSE (FRANCE)

Gayet-Mengelle C.*, Puel Jacqueline*, Averous S.**, Bazex J.**
*Laboratoire de Virologie, CHU Purpan, Toulouse, FRANCE.
**Service de Dermatologie, CH La Grave, Toulouse, FRANCE.

Objective. To assess the risk of contamination through prostitution (male or female) in our city.
Methods. We systematically screened anti HIV-1 antibodies in 97 female prostitutes (9 coming from Ghana and 35 travestites or transsexuals, regularly consulting at the Venereal Diseases Centre since May 1985, to January 1989. Screenings were realised using 2 immunoenzymatics techniques (Abbott and Wellcome). All positive sera were confirmed by the Western-blot assay (Du Pont De Nemours)
Results. 5 of the 97 prostitutes were seropositive : we screened the first one in 1985, two others in 1986, one in 1987, and one who seroconverted in 1988. But two of them were intravenous drug abusers, so it was not possible to incriminate sexual transmission with certainty. None of the Ghanean was seropositive. Among the travestites and transsexuals, one patient seroconverted in 1985, and 3 patients were seropositive (2 in 1986 and 1 in 1987). For these patients drug addiction is unknown.
Conclusion. The prostitue population of Toulouse seems to be relatively free of HIV-1 contamination. But these results do not entirely reflect the true situation as a marginal prostitution also exists with people who are generally not subject to any control. Although these results are relatively reassuring, elementary precautions must be taken to prevent the spread of the disease, since contamination through prostitution has been shown to be a real risk.

M.A.P.47

CLIENTS OF PROSTITUTES:- A REVIEW.

*Kynaston A, *Bisset C, ¯Burns SM, *Brettle RP.
*HIV Counselling Clinic; ¯Regional Virus Laboratory; City Hospital, EDINBURGH, Scotland.

OBJECTIVE: To study the responses of clients of prostitutes to health risks including HIV and sexually transmitted diseases (STD).
METHOD: The City Hospital HIV Counselling Clinic offers self referred individuals confidential pre/post test counselling. The number of clients of prostitutes using condoms, who have regular sexual partners, history of STD, HIV antibody status and socio-economic status were noted.
RESULTS: Of 1627 patients who have attended between October 1985 and October 1988, 73 were clients of prostitutes. Their socio-economic status was as follows:- 17 Professional/Managerial, 27 Skilled, 16 Semi-Skilled, 2 Un-Skilled, and 11 Unknown. 2(*) clients tested HIV +ve. They were also injection drug users (IDU), still sharing needles, never using condoms and both had regular partners.

Condom Use	N	Regular Partner	History of STD	Client also IDU	HIV Test +ve	-ve	N/T
Always	11	0	1	0	0	9	2
Sometimes	12	10	4	0	0	11	1
Never	50	36	14	2*	2*	41	7

CONCLUSIONS:
1) Safer sex not being practised.
2) Those clients with regular partners tend not to use condoms.
3) Prostitutes are at risk from clients.
4) Given the relatively high socio-economic status of the group it is suprising that education has not altered behaviour.

M.A.P.48

HIV SEROPOSITIVITY AND RISK BEHAVIOURS OF ITALIAN PROSTITUTES

Tirelli, U.*; De Mercato R.°; Caprilli, F.**; Giuliani, M.**; Saracco, Alberto*** and Rezza G.°°
From the GICAT: * AIDS Activiy Unit, Centro di riferimento oncologico Aviano; ** Istituto Dermatologico S. Gallicano, Roma; *** Istituto Mal. Inf. Osp. "Sacco", Milano; ° II Clinica Medica Univ. Napoli; °° Ministry of Health, Roma - ITALY-.

Objective; To estimate HIV seroprevalence among prostitutes in different Italian areas. To study risk behaviours associated to HIV seropositivity in female prostitutes.
Methods. The study has been conducted in Rome, Milan, Naples and Pordenone. Different sources have been utilised in order to contact female prostitutes: STD clinics, AIDS facilities, organised prostitutes agencies. In particular, a collaboration with the Commitee for Civil Righs of Prostitutes was set up. Serological, clinical, demographic and sociological data were collected. An individual questionnaire was administred in order to collect information about risk behaviours and sexual practices.
Results. Three hundred and five female prostitues were studied. Anti-HIV antibodies were found in 3 out of 192 non-drug-injecting prostitutes (1.5%) one of those developed AIDS, representing the only clinical case reported in a non-addicted prostitute in Italy. Among drug-injecting prostitutes, 41 out of 113 were anti-HIV seropositive (36.2%).
Conclusion. HIV seroprevalence is very low in non-drug-injecting prostitutes. The high prevalence of seropositivity among drug injecting prostitutes might account for the spread of HIV infection in the heterosexual active population.

M.A.P.49 FEMALE PROSTITUTES IN ANTWERP: A RISK GROUP FOR HIV INFECTION

Praets Christ'l, Laga, M., Van Royen, P., Peeters, M., Hendrickx, C., Piot, P.
Institute of Tropical Medicine, Antwerp, Belgium

Objective: To assess the prevalence of STD's, including HIV, among female prostitutes, and to determine their preventive health attitudes and behaviour, and perception of their clients' behaviour.
Methods: Prostitutes were recruited through general practitioners and a prostitute organization. A standard questionnaire was administered and blood was collected for HIV, syphilis and hepatitis B serology.
Results: So far 88 women were recruited, including 20 % street walkers, 20 % windowworkers, 37 % bar and brothel workers, and 9 % call girls. The median age was 31 years and 22 % had started prostitution less than 1 year ago. Only 4 women had ever used IV drugs. One (non IVDU) women was HIV positive (1.16 %, .03-6.3 95 % CI). 6.1 % and 25 % had markers for syphilis and hepatitis B respectively. 37 % had been tested at least once for HIV. 60 % had always been using condoms for at least one year. 4 of 7 women practising anal intercourse always use condoms and 36.5 % of women did not always use condoms during vaginal intercourse. According to 54 % of the women the client rarely proposes the use of condoms. 45 % of the prostitutes had to insist on using condoms and 63 % confirmed to have clients who definitely refuse condoms.
Conclusions: HIV infection seems rather uncommon in Antwerp female prostitutes. Many women have recently changed their behaviour for fear of AIDS. Because of the continuing risk behaviour from both colleagues and clients particular prevention programs are still required.

M.A.P.50 RISK OF HIV INFECTION AMONG HOMELESS IV DRUG USERS (IVDUs) IN CHICAGO

Wiebel, Wayne; Lampinen T; Chene D; Jimenez D; Johnson W; Ouellet L et al
University of Illinois at Chicago, Epidemiology Program, Chicago, IL 60612

Objective: To examine the relationship between homelessness and HIV infection in a group of active IVDUs not in treatment.
Methods: Analysis of 404 face-to-face interviews conducted between 3/88 and 8/88 was performed as part of a large-scale prevention and education project funded by the National Institute on Drug Abuse. IVDUs were recruited using street-based indigenous outreach workers and were paid for participation.
Results: Fully 23.6% of the sample considered themselves homeless. Homeless IVDUs were significantly more likely to be HIV-seropositive (33.7%) than non-homeless IVDUs (20.3%); (X^2=7.05, p<.01). This relationship was found across all levels of reported needle-sharing partners in the 6 months prior to interview (Table 1).

Number needle-sharing partners	% HIV-seropositive Home	Homeless	Homeless %	Sample size
0	13.9	25.0	14.3	84
1-2	15.7	26.9	22.6	115
3-6	28.0	39.3	25.5	110
7+	32.4	45.0	37.0	54

Conclusion: Homeless IVDUs are overrepresented among those reporting the greatest numbers of needle-sharing partners. These IVDUs are more likely to be seropositive, suggesting that homelessness exerts an independent effect upon risk for HIV-seropositivity. This relationship was most significant for Puerto Rican IVDUs. The relationship of other risk factors is discussed.

M.A.P.51 HIV INFECTION AMONG HOMELESS MEN IN A NEW YORK CITY SHELTER.

Torres R. Torres*; Mani S**; Altholz J*; Brickner PW*. *St. Vincent's Hospital and Medical Center; **Mt. Sinai Hospital and Medical Center, New York, N.Y. USA.

Objective: Shelters for homeless men in New York City have a high prevalence of intravenous drug use and active tuberculosis. A study was conducted to describe the characteristics of homeless men voluntarily tested for HIV antibodies, between 1985-1988, at a public shelter in NYC, which houses 1200 men.
Methods: One hundred and seven homeless men were voluntarily tested for HIV antibodies. Testing was recommended to men with high risk behavior, if signs or symptoms suggestive of HIV infection were present, or as part of routine physical exam for a work program. Charts were reviewed retrospectively.
Results: Sixty-six percent of homeless men tested were HIV seropositive. Intravenous drug use (IVDU) and active pulmonary (PTB) or extrapulmonary tuberculosis (EPTB) were significantly associated with HIV seropositivity. No significant differences in rates of PPD reactivity, positive RPR or hepatitis B antibody were present:

	HIV Positive No.	(%)	HIV Negative No.	(%)	P Value
IVDU	48	(66)	12	(33)	<0.001
Homo/Bisexual	19	(37)	10	(27)	<0.9 NS
+ PPD	31	(69)	14	(31)	<0.2 NS
Active PTB, EPTB	20	(87)	3	(13)	<0.05

Active tuberculosis was significantly associated with a diagnosis of AIDS or ARC (P<0.001), but not with a diagnosis of asymptomatic carrier or PGL. Mean CD4 counts were lower (196 vs. 531) for HIV positive men with active TB, than without TB. Rates of compliance were similar among HIV positive and HIV negative men; 70% in both groups returned for HIV results.
Conclusion: HIV infection among homeless men in a NYC shelter is significantly associated with IVDU and active tuberculosis. Strategies to prevent homelessness are likely to influence rates of IVDU, TB transmission and HIV transmission.

M.A.P.52 PREVALENCE AND RISK FACTORS FOR HIV-1, HIV-2 AND HTLV-I INFECTION IN PROSTITUTES IN SOUTHERN CATALONIA.

Casabona, Jordi*, Salinas, R**, Sánchez, E*, Lacasa, C* and Verani, P***.
* Epidemiology Section. AIDS Program. Generalitat de Catalunya. Barcelona, Spain.
** Hosp. "V. de la Cinta". Tortosa, Spain. *** Inst. Sup. de Sanitá. Roma, Italy.

Objectives. 1.- To estimate the prevalence of HIV-1, HIV-2, HTLV-I, hepatitis B and luetic infection among prostitutes, and 2.- To identify possible risk factors for HIV-1 transmission in this collective.
Methods. Due to both the large number of prostitutes and the easy access to them, an area in southern Catalonia characterized by the lack of street prostitution was chosen. Through the local network all prostitution bars were identified and all their working women request to participate in the study. We used a previously validated questionnaire with 45 items on demographic and behavioral data. After asking for consent, two of the authors interviewed the participants and took blood samples at the workplace. Seventy-five women were identified and 4 of them refused to answer the questionnaire, but blood was drawn from all them.
Results. Sixty-five (91.55%) of the women used condoms with either their clients or their partners. Only 3 out of 46 prostitutes with a stable heterosexual partner used condoms with both the partners and the clients. Eight prostitutes were IVDU and 6 had an IVDU partner. Eight (10.67%) women were positive for HIV-1, 6 (8%) for HBsAg, 24 (32%) for HBcAb, and 3 (4%) for the luetic test; HIV-2 and HTLV-I results will be presented. Only the use of intravenous drugs by the prostitutes was significantly associated with HIV infection, in both univariate (p<0.0017) and multivariate (p=0.0014) analysis. The same association was found after stratifying by condom use and IVDU partner.
Conclusions. We point out the importance of using the most exhaustive population possible in a well defined area. We suggest the use of a multicentric approach, stratifying by type of prostitution, with a bigger population that could allow to identify other associations. In our setting where IVDU account for the majority of AIDS cases, and most of the index cases of heterosexual acquired HIV infection are IVDU, the use of drugs by the prostitutes or by their sexual partners seems also to be the most important risk factor in that collective.

M.A.P.53 SOCIAL AND SEROEPIDEMIOLOGIC SURVEY FOR ANTIBODIES TO HUMAN IMMUNODEFICIENCY VIRUS AND OTHER SEXUAL DISEASES IN PROSTITUTES IN RIO DE JANEIRO.

De Maia, C.; Vasconcellos, A.; Linhares, D.; and **Andrade-Serpa, Maria José**.
Basic Research Centre, National Cancer Institute, Rio de Janeiro, Brazil.

Objective. To evaluate the sexual behaviour, social and economic conditions, and the incidence of HIV-I infection, syphilis and hepatitis B antigen among female prostitutes in Rio de Janeiro.

Methods. Anonymous questionnaires were answered by 49 prostitutes and sera samples collected from 69 female prostitutes. For anti-HIV-I, the samples were screened by ELISA (Organon) and the positive ones were submitted to two other tests, a competitive ELISA (Behring) and a recombinant EIA (Abbott). Syphilis infection was detected by microscopic flocculation and hepatitis B antigen by EIA (Abbott).

Results. Eight out of 69 (11.59%) of samples were positive for anti-HIV-I, 48 out of 68 (70.58%) positive for syphilis infection and only 1 serum (1.44%) presented positivity for hepatitis B. The choice of a promiscuous sexual life has been due to economic troubles in 81.63% and condom use in high rate has been observed only in 20.40% of prostitutes interviewed. The frequency of partners per day shows variation: 40.85% of prostitutes have 1 to 5 partners, 38.77% with 6 to 10, and 20.40% declared to have more than 10 partners per day.

Conclusions. These preliminary results suggest that HIV-I infection and other sexual diseases have a very high incidence among females with a promiscuous sexual life and that can play an important role in the HIV-I heterosexual transmission in Brazilian cities.

Le VIH chez les clients des cliniques de MTS et des centres de dépistage
HIV Among Clients of STD Clinics and Testing Centres

M.A.P.54

HIV SEROPREVALENCE IN HETEROSEXUAL MEN AND WOMEN, DENVER METRO STD CLINIC, 1985-1988.

Judson, Franklyn; Cohn, D.; Douglas, J. Denver Public Health, Denver, Colorado, USA

Objective. To monitor the course of the HIV epidemic through seroprevalence surveys in an urban STD clinic.
Methods. Each year, 1985-88, sera of consecutive, unselected STD clinic patients in defined risk behavior (RB) groups were tested for HIV antibody (ELISA, WB confirmed). HIV positive patients without a stated risk for HIV infection were reinterviewed to ensure correct RB categorization.
Results.

RB Group	No. HIV Positive/No. Tested (%)				
	1985	1986	1987	1988	Total
Gay Men	58/119(48.7)	60/123(48.8)	72/192(37.5)	67/140(47.9)	257/572 (44.9)
Female Prostitutes	1/12 (8.3)	0/184(0.0)	2/137(1.5)	1/39 (3.0)	4/372 (1.1)
IVDU					
Males	2/29 (6.9)	1/49(2.0)	4/126 (3.2)	0/69 (0.0)	7/273 (2.6)
Females	0/10 (0.0)	0/20(0.0)	0/64 (0.0)	2/26 (7.7)	2/120 (1.7)
Heterosexuals					
Males	0/229(0.0)	1/361(0.3)	1/374(0.3)	3/670 (0.4)	5/1634 (0.3)
Females	0/111(0.0)	1/222(0.5)	1/255(0.3)	0/351 (0.0)	2/ 940 (0.2)

Of 2,574 non IVDU heterosexual men and women at high risk of STD only 7 (0.3%) were HIV positive including 3 with IVDU sexual contact. Three of 4 positive female prostitutes were IVDU.
Conclusions. By 1988, at least 10 years after the first HIV infection in Denver, there is no evidence that the HIV epidemic is advancing beyond gay men, IVDU, and their sexual contacts. Accurate epidemiology requires correct RB categorization using confidential reinterviews.

M.A.P.56

HIV SEROPREVALENCE IN PATIENTS WITH PID

Sperling, Rhoda S., Friedman, F.
Dept. of OBS/GYN, Mount Sinai Medical Center, NY, NY, USA.

Objective. 1. To determine the seroprevalence of HIV in women with PID and, 2. To determine whether HIV seroprevalence in PID patients is linked to non-IV cocaine use and/or serologic evidence of past/present syphilis.
Methods. The GYN Clinic Service provides care to indigent minority women from areas of NYC hit hard by AIDS. From 11/1/88-1/15/89, all clinic PID admissions had serum samples, which were drawn for syphilis serology, anonymously screened for HIV antibody. All PID patients were routinely offered HIV testing in addition to routine GC, chlamydia, and syphilis screens. Sexual and drug use history were obtained on all patients.
Results. 21 patients were admitted; 16 had specimens suitable for anonymous testing. 3/16 (18.8%) were seropositive. 12/21 (57%) patients requested confidential screening; 3/12 (25%) were seropositive.
Of the known seropositives:

- All reported illicit drug use
  (1/3 IVDA; 2/3 non IV cocaine)
- 2/3 reported sexual contact of men at risk
  (1IVDA;,1 non-IV cocaine)
- 0/3 had positive syphilis serology
  (3/21 (14.3%) of PID admissions had positive serology; 2/3 (67%) were consistent with acute infection.)

Conclusions. In the small sample of PID patients screened 1. 18.8% seropositive rate. 2. HIV antibody found in non-IV cocaine user without other known risk behavior. 3. No association between HIV seropositivity and positive syphilis serology was demonstrated.

M.A.P.58

HETEROSEXUAL TRANSMISSION OF HIV IS RARE AMONGST ATTENDERS AT AN STD CLINIC IN LONDON

Barlow D. Bradbeer C S, Thin R N, Christie I, Palmer S, & Banatvala J E. Dept of GU Medicine and Virology, St Thomas' Hospital, London, UK

Objective: To assess HIV seropositivity amongst attenders in an STD clinic.
Methods: All patients undergoing routine blood tests for syphilis between June 1988 and April 1989 were offered an HIV test (Abbot/Wellcome) competitive the result of which could be anonymous.
Results: By the end of December 1988, 4,972 patients had been entered into the study. Of these, 453 patients (9.1%) declined the HIV test. Those declining included a higher percentage of homosexual men but were otherwise similar to those agreeing to the test. 4519 attenders were tested, 814 (18%) of whom wished their result to be anonymous.

35 of 4519 (0.8%) were HIV antibody positive. 27 of 247 homosexual or bisexual men (10.9%) and 8 (3 women, 5 men) of 4261 heterosexuals (0.19%) were positive. 11 homosexual women were negative. 2 of 27 homo/bisexual positives and 6 of 8 heterosexual positives were Afro-Caribbean. 211 patients from Africa (184 from West Africa) were negative for HIV2).

HETEROSEXUAL POSITIVES

	from High-risk area	IVDA/Contact	No risk factors	Total tested
Male	3	1	1	2236
Female	2	1	0	2025

Conclusion: This sexually active population with a higher than average prevalence of gonorrhoea, chlamydia and other STD's has low HIV seropositivity in spite of the potential for importing cases from endemic areas.

M.A.P.55

COMPARISON OF RACE/ETHNICITY, TRANSMISSION CATEGORY IN PERSONS ELECTING HIV COUNSELING AND TESTING SERVICES

Cahill, Kathy*; Bowen, G.S.*; Kirby, C.*
*Centers for Disease Control, Atlanta, GA, U.S.A.

Objective: An evaluation of voluntary HIV counseling and testing services by race and transmission category in the United States.
Methods: Twenty-five States, with a population of 142,000,000 (63% of the total U.S. population), provided demographic and risk factor information on all persons seeking public sector, voluntary HIV counseling and testing services (CT) for the period July-September, 1988.
Results: There were a total of 83,853 persons tested, 5% were seropositive. An analysis of race/ethnicity showed that of the total tested 54% were white, 22% black, 7% Hispanic, <1% Asian, <1% Native American and 17% were undetermined. Compared to the racial/ethnic composition of the population of these States (77% white, 13% black, 7% Hispanic, 1% other), a higher proportion of blacks received CT services than did whites or Hispanics. A higher proportion of Hispanics (11%) who elected testing than blacks (6%) or whites (5%) were seropositive. The transmission category of persons electing testing were: heterosexuals, 40%; homosexual males, 14%; IV drug users, 8%; homosexual males/IV drug users, 0.5%; blood recipients, 2%. Among those electing to be tested, the prevalence of infection was 18% for homosexual men, 12% for IV drug users, 24% for homosexual/IV drug users, 1.5% for heterosexuals and 1.9% for blood transfusion recipients.
Conclusion: The demand for counseling and testing services in the U.S. is increasing rapidly. A higher proportion of persons receiving CT services are from minority populations than their representation in the population. The majority of people receiving CT services are not in the highest risk transmission category; only 14% of those tested were homosexual men and 8% were IV drug users. Eighteen percent of homosexual men and 11% of IV drug users electing testing were infected.

M.A.P.57

RISK FACTORS FOR HIV-1 INFECTION IN A BRITISH POPULATION

Beck, E.J.; Donegan, C.; Kenny, Colin; Cohen, C.S.; Moss, V. W.; Terry, P. et al
St Mary's Hospital, Praed Street, Paddington, London, United Kingdom

Objective. Determine risk factors for HIV-1 infection and monitor testing trends in attendees at a London sexually transmitted diseases clinic.
Methods. Behavioural characteristics of individuals attending for HIV-1 testing were collected. HIV tests performed by screening with a competitive ELISA (Wellcome®) and antibody capture ELISA (Abbott®) as confirmatory test.
Results. Between September 1985 and June 1988, 6923 individuals were tested, 558 (8%) were seropositive. Of these 523 (94%) were men and 35 (6%) women. The seroprevalence pattern conforms to that currently observed in other industrialized nations. However, risk factors for HIV-1 seropositivity in the women (n=2373) were heterosexual intercourse with an HIV infected partner (RR 141; 95% CI 77-258), intravenous drug use (RR40; 95% CI 18-90) and heterosexual contact with a Central African resident (RR27; 95% CI 10-74). Risk factors for men (n=4550) were heterosexual contact with HIV infected partner (RR116; 95% CI 65-207), being homosexual or bisexual (RR95; 95% CI 58-155), intravenous drug use (RR42; 95% CI 21-83) and heterosexual contact with a resident from Central Africa (RR16; 95% CI 6-46). Testing trends showed a sustained increase in number of individuals tested. This coincided with periods of increased media attention on HIV infections/AIDS, involving both Government and popular press/TV campaigns. The most pronounced increase was observed in heterosexual males and females with no other risk factors.
Conclusions 1) Heterosexual and homosexual transmission were implicated in this British population. 2) The media campaigns have increased awareness of HIV infection/AIDS as a major public health problem.

M.A.P.59

HIV PREVALENCE IN AN AIDS COUNSELLING CENTER IN ISRAEL

Handzel, Zeev T.; Burstein, R.; Meyer, M.; Levinstein, R.; Nave, R. and Bentwich, Z.H.
Kaplan Hospital, Hebrew University Medical School, Rehovot, Israel.

Objective. To determine HIV prevalence among risk groups in an AIDS center in Israel.
Methods. All applicants to the AIDS clinic started at our center in 1983, were interviewed and tested for HIV. They included male homosexuals (MHS), I.V. drug addicts (IVDA), recipients of blood transfusions (BT) as well as non-risk group applicants (N).
Results. The number of individuals tested and results were:

Groups	1985	1986	1987	1988
MHS	347	183	194	233
IVDA	2	7	11	22
BT	1	3	47	9
N	56	106	514	415
Total	406	299	768	681
% HIV + in risk group	10	10	8.7	6.8

Thus, the proportion of non-risk group applicants clearly increased while that of MHS and percentage of HIV seropositively diminished.
Conclusions. a) The low prevalence of HIV infection among risk groups in Israel may be correlated with the still low incidence and growth of AIDS in Israel. b) The AIDS counselling center is being overused by the wide public, while risk group members do not use it sufficiently.

M.A.P.60 TRENDS IN HIV SEROPREVALENCE AMONG SELF-IDENTIFIED RISK GROUPS UTILIZING ANONYMOUS TEST SITES IN SAN FRANCISCO

Greenhalgh, John B.*; Wilson, MJ**; Nguyen, BH*; Lemp, GF*; Evans, PE*; Rutherford, GW.*
*San Francisco Department of Public Health and **California Department of Health Services, San Francisco, California, U.S.A.

Objective. Describe trends in HIV seroprevalence within specific risk groups using Anonymous Test Sites (ATS) in San Francisco.
Methods. During the 36-month period July, 1985 to June, 1988, demographic and risk information was collected by self-administered questionnaire from 41,808 clients visiting the ATS for the first time for HIV antibody testing.
Results. HIV SEROPREVALENCE BY QUARTER (7/85 - 6/88)

	1985		1986				1987				1988	
	3	4	1	2	3	4	1	2	3	4	1	2
Heterosexual	2%	2%	1%	3%	1%	1%	1%	1%	0%	1%	0%	1%
Gay/Bisex.Men	34	36	36	37	35	36	33	37	40	42	36	38
IV Drug Users	9	5	8	4	8	9	5	8	3	7	12	6
Gay/Bi IVDUs	57	72	68	74	54	71	68	55	62	74	65	50
All Clients	27	27	28	30	23	22	18	17	21	20	22	20

Complete risk group data were available for 63% of those tested for HIV antibody. Overall seroprevalence declined from 27% in July, 1985 to 20% by June, 1988 ($p<.001$) due to increasing rates of heterosexuals served (37% of all clients initially vs. 63% during the final quarter) and decreasing usage by gay/bisexual men (76% initially, declining to 24%).
Conclusions. Despite marked shifts in utilization patterns at the ATS, HIV seroprevalence within major risk groups has remained relatively constant.

M.A.P.61 TRENDS IN HIV SEROPREVALENCE IN AN URBAN SEXUALLY TRANSMITTED DISEASE CLINIC, 1986-1989.

Handsfield, H. Hunter, Sohlberg E, Hopkins S, Swenson PD, Harris N. Seattle-King County Department of Public Health and University of Washington, Seattle, Washington, USA.

Objective. To determine trends in the prevalence of HIV infection in an urban sexually transmitted disease (STD) clinic over 2.5 years.
Methods. In a public STD clinic, HIV antibody was assayed in initial-visit patients who had syphilis blood tests in Oct-Nov 1986 (N=367), Aug-Sep 1987 (N=352), Feb-Mar 1988 (N=382), and Sep-Nov 1988 (N=1610); 1989 results are pending. Serum and demographic/risk data were de-linked from identifiers prior to HIV ELISA; positives (HIV+) were confirmed by Western blot. Trends were analyzed by chi square for linear trend. HOM=homosexual and bisexual men; HET=heterosexuals; IVDU=intravenous drug users.
Results. HIV+ rates for the 4 periods were: HOM 14/24 (58%), 7/18 (39%), 17/30 (57%), and 41/101 (41%) (P=0.17); HET IVDU 0/12, 0/13, 0/15, and 5/79 (6%) (P=0.06); HET non-IVDU 0/329, 0/291, 1/337 (0.3%), and 7/1418 (0.5%) (P=0.04); all HET 0/341, 1/330 (0.3%), 1/352 (0.3%), and 12/1502 (0.8%) (P=0.02). Among HET in Sep-Nov 1988, HIV+ included 8/967 (0.8%) males and 4/528 (0.8%) females; 2/858 (0.2%) whites and 9/464 (1.9%) blacks (P=0.001); and rose steadily with age through age 35-39 (P=0.02).
Conclusions. From 1986 through 1988, HIV seroprevalence was apparently stable in STD clinic HOM. By contrast, the HIV+ rate rose in HET, primarily in blacks and IVDU, and with increasing age. STD clinic patients, especially ethnic minority HET, IVDU, and their sex partners, are among the highest priority target groups for HIV counseling and testing and other behavioral interventions.

M.A.P.62 EFFECTIVENESS OF VOLUNTARY HIV ANTIBODY TESTING PROVIDED AT A CLINIC TREATING SEXUALLY TRANSMITTED DISEASES

Ginsberg, Michele M.*
*San Diego County Department of Health Services, San Diego, CA, U.S.A.

Objective: To characterize Sexually Transmitted Disease (STD) Clinic attendees who elect to receive HIV antibody testing and fail to return for results.
Methods: Patients presenting at STD Clinic were offered the opportunity to have HIV antibody testing to obtain the results at a second visit. Patients who participate, complete a questionnaire regarding sexual orientation, IV drug use, etc. ELISA positive specimens were tested by Immunofluorescent Antibody.
Results: Between June and August 1988, 1085 patients attending clinic for evaluation of STD were tested for HIV antibody. Forty-six percent returned for test results. Rate of return were as follows: positive-57.6%; negative-41.7%; total males-47.3%; total females-36.9%. Rate of return by transmission category; homosexual males-72%; bisexual males-57.8%; heterosexual males-48.7%; heterosexual male IV drug users-27.9%; heterosexual females-39.9%; female IV drug users-26.9%. Return rates by ethnic group: white-55%; black-29.3%; hispanic-41.8%.
Conclusion: Return for HIV antibody test results among patients tested while seeking STD services are poor. Homosexual and bisexual males, groups with hightened awareness of their risk of HIV infection, were most motivated to return for results. Heterosexual, IV drug users, females and non-whites had high failure rates. Increased educational efforts and improved strategies to motivate these groups must be developed.

M.A.P.63 EPIDEMIOLOGICAL OBSERVATIONS OF A TERRITORIAL HIV SCREENING CENTRE IN MILAN.

Schiantarelli, Clara; Rastrelli, M.; Moioli, M.C.; Reini, MR; Orso, MR; Villa, M.R.
Niguarda Ca' Granda Hospital, Milan, Italy.- * Public Health Office of Milan, Milan, Italy

Objective. To study epidemiological patterns of HIV diffusion in open population in an Italian urban territory.
Methods. During the period Dcember 1985-December 1988, a territorial out-patients Department for AIDS prevention had been operating in a town district (Milan 13, population 28.956) dealing with information, spontaneously requested diagnostic examinations and follow-up of people at risk. 2.296 subjects asked for serological assay and were examined (1530 males, 766 females); 551 declared themselves intravenous drug addicts (IVDAs), 168 homo- or bisexual, 1.020 having had heterosexual intercourses partners), 73 family contacts, 57 blood recipients, 91 exposed to professional risk. The determination of anti-HIV Ab was performed by ELISA and WB methods.
Results. Evidence of infection was observed in 270 IVDAs (49.0% of the group), 16 homo/bisexual (9.5%). In the group of heterosexual intercourses 25 cases of seropositivity were registered: among them, 16 were heterosexual partner of surely HIV infected persons.
Conclusions. In the population considered, the group of IVDAs suffers the highest percentage of seropositivity, at comparable levels as to Italian data, whereas the percentage of homo/bisexual is lower than the national average. 9.8% among partners of surely seropositive subjects resulted infected, indicating the important standard of risk of HIV diffusion via heterosexual intercourse.

M.A.P.64 HIV SEROPREVALENCE SURVEYS IN THE SAN FRANCISCO BAY AREA

Wilson, Mary Jess*; Greenhalgh, JB**; Lemp, GF**; Perkins, CI*; the Bay Area Cooperative Study Group; et al.
*California Department of Health Services, Sacramento, California and**San Francisco Department of Public Health, San Francisco, California, U.S.A.

Objective. To estimate HIV seroprevalence in the San Francisco (SF) Bay Area.
Methods. Seroprevalence surveys in sexually transmitted disease (STD), women's health, tuberculosis and drug treatment clinics were begun in the 6-county SF Bay Area in 1988. We have collected 16,000 specimens in 1988 and will collect an additional 35,000 in 1989. With active participation from each health jurisdiction and the Centers for Disease Control, standardized research protocols were developed for conducting non-blinded and blinded HIV serosurveys. Available data on blinded HIV antibody testing from 5 health jurisdictions adjacent to SF were analyzed by demographic characteristics and risk group. Comparable data are not yet available from SF clinics.
Results. 52 (1.9%) of 2770 specimens were repeatedly ELISA reactive and confirmed positive by Western blot analysis. Among STD clients, males had a significantly higher rate of positivity (2.7%) than did women (0.7%) ($p=.005$). Homosexual/bisexual men were significantly more likely to be positive (22%) than those with undetermined risk (3%) or all other risk groups (0.7%) for specimens for which risk factors were obtained. Seroprevalence among STD clients did not significantly differ across age groups or across counties.
Conclusion. The 1.9% seroprevalence in selected clinics demonstrates the scope and geographic distribution of the HIV epidemic for counties adjacent to a major AIDS epicenter.

M.A.P.65 HETEROSEXUAL TRANSMISSION OF HIV: PREVALENCE AND RISK FACTORS

Guinan, James*; Stone, C.*; Morlet, A.*; Gold, J.*.
* Albion Street (AIDS) Centre, Sydney Hospital, Sydney, Australia.

Objective. To determine the prevalence and risk factors associated with HIV infection in heterosexuals requesting HIV antibody testing.
Methods. Between March 1985 and December 1988, risk factors of heterosexuals who tested positive for HIV antibody testing were assessed.
Results. During the 42 month period, 5482 heterosexuals (3544 men and 1938 women) were tested for HIV antibody. Fifty one (0.9%) were found to be HIV antibody positive. These included 37 men and 14 women. The majority (58.8%) were intravenous drug users (IVDU's), with more male IVDU's infected (22) than women (8). Seven clients (5 men and 2 women) were found to be infected by contaminated blood, and one woman by a contaminated artificial insemination. Sexual contact was the only identified risk factor in 25.5% (13). Seven of these were men who nominated prostitute contact as a risk factor, while all of the remaining 6 HIV antibody positive heterosexuals (3 men and 3 women) had sexual partners who were known to be HIV infected.
Conclusion. Intravenous drug use was the major HIV risk factor among heterosexuals. However, sexual intercourse was the only identified risk factor in a sizable proportion of clients. These results indicate that although IVDU's remain a high priority group to be targeted in education and behaviour change programs, sexual behaviour change in the broader population is also necessary if HIV transmission is to be arrested.

M.A.P.66 PREVALENCE OF UNSUSPECTED HIV-INFECTION AMONG STD-PATIENTS IN ANTWERP, BELGIUM.

Dirk Avonts, Laga M., Van den Bruaene M., Goilav C., Vercauteren G. and Piot P.
Institute of Tropical Medecine, Antwerp, Belgium.

Objective. To define the prevalence of HIV unsuspected infections among STD patients unaware of their HIV serostatus.
Methods. In 1988 all new patients consulting an STD-clinic in Antwerp, Belgium, and unaware of possible seropositivity, were screened for the presence of HIV-antibodies. During the same year 50 persons with HIV-infection were being followed at the same clinic. Confidential testing (with patients consent) was offered for those who wanted to know their serostatus, whereas anonymous testing (results were not identifiable for patient and physician) was performed for the others. Only patients residing in Belgium were included in the study. All sera were examined with an Enzyme-Immuno-Assay test (Vironostika anti-HTLV III-microelisa system, Organon technica) and positive sera were confirmed with Western Blot (Dupont de Nemours).
Results. Prevalence of HIV-infected patients : % and 95% confidence interval (CI).

patients	number/total	% (95 % CI)
male heterosexuals	1/345	0.29 (0.01-1.63)
male homosexuals	1/44	2.27 (0.06-12.02)
female heterosexuals	2/255	0.78 (0.10-2.80)
female prostitutes	0/64	0 (0.00-5.60)
seamen	0/45	0 (0.00-7.87)

Of a total of 753 patients tested, 522 (69.3%) were tested confidentially and 231 (30.7%) anonymously. Four seropositive patients were detected (0.53%) and all were tested confidentially.
Conclusion. These data suggest a low prevalence of HIV-infection in heterosexual Belgian patients consulting for STD-related problems, despite a high proportion (>20%) of non IVDU heterosexuals among Belgian AIDS patients.

M.A.P.67 HIV-1 INFECTION IN NEW YORK CITY STD CLINIC PATIENTS: EVIDENCE FOR STABLE SEROPREVALENCE, 1987-1988

Weisfuse, Isaac B., Chiasson, MA; Beck, S; Ramirez, L; Greenberg, B; Ewing, W; et al. New York City Department of Health, NY, NY. U.S.A.

Objective. To determine HIV-1 seroprevalence in patients at New York City STD clinics, and to compare rates over time in one clinic.
Methods. Blinded serosurveys were conducted among STD clinic patients in one clinic in 1987 and in all 12 STD clinics in 1988. The interval between the 2 surveys was 18 months. Specimens were obtained from routine syphilis testing and were analyzed for HIV-1 by ELISA with confirmatory Western Blot. Data on age, race/ethnicity, diagnosis and RPR result were collected.
Results: In 1988, 195/2533 (7.7%) of clinic attendees were HIV-1 positive. The highest rate (12.1%) was found among clinic attendees age 30-39. Among those diagnosed with a genital ulcer (GU) at the time of visit, 23/173 (13.3%) were HIV-1 positive as opposed 123/1782 (6.9%) with other diagnoses ($p<.05$). For the clinic surveyed in both years, 26/348 (7.3%) were positive in 1987 and 34/694 (4.9%) positive in 1988. This difference was not statistically significant. In both 1987 and 1988 patients with GU were significantly more likely to be HIV-1 seropositive than were patients with other diagnoses, OR=2.3, p=.02 and OR=2.9, p=.04 respectively.
Conclusions. HIV-1 is a common infection in New York City STD clinic patients and those with a GU are more likely to be infected. Seroprevalence remained constant in one STD clinic over an 18 month interval. The data support expanding the availability of HIV-1 counseling and testing in all STD clinics.

M.A.P.68 CHARACTERIZATION OF HIV INFECTED STD CLINIC CLIENTS IDENTIFIED THROUGH ROUTINE VOLUNTARY SCREENING: IMPLICATIONS FOR FUTURE HEALTH CARE NEEDS

Erickson, Beth*;Glasser,D.*;Wasserheit,J.N.**;Rompalo,A.M.**;Brathwaite,W.*and Hook III,E.W.**. *Baltimore City Health Dept., **Johns Hopkins Univ., Baltimore, USA.

Objective. To describe demographic and historical characteristics of HIV infected patients identified by a routine voluntary screening program in Baltimore STD clinics.
Methods. Consenting patients are screened for HIV-1 using commercially available EIA, confirmed using a licensed Western Blot test, and are given appointments to return for test results. During January-October 1988, there were 18,907 patient visits to the STD clinics; 12,795(66%) were tested for HIV. Of patients tested, 531(4%) were HIV-infected and to date, 321(60%) have returned for results and further evaluation.
Results. HIV infected patients were predominately (approximately 2/3) young, black, single males. High risk behavior was common among infected patients: 33% reported homosexual exposure, 37% reported prior IV drug use, and 39% reported exposure to a sex partner at risk for HIV. No traditional risk factors for HIV infection were acknowledged by 18% of infected patients. STDs were also common in infected patients; 42% reported prior syphilis and 17% had been treated for syphilis in the preceeding year. The majority of patients were asymptomatic(71%) or had generalized lymphadenopathy(18%) at the time of diagnosis. Many of these patients have few health care resources available; 93% were unmarried and 69% had either no health insurance(45%) or were covered solely by public assistance health plans(24%).
Conclusion. Routine, voluntary HIV screening is a well accepted, useful means to identify HIV infected individuals in high risk settings such as STD clinics. Identification of these individuals may provide useful information for projecting future health care needs.

M.A.P.69 FREQUENCY OF HIV INFECTION AMONG PATIENTS OF STD OUT-PATIENT CLINIC

Stępiński A., Mazurkiewicz W., Wójtowicz U., Napiórkowska T., Babiuch L.
Medical Academy Warsaw, Poland

Objective.The incidence of HIV antibodies has been investigated in 1327 patients with various STD,1022 males and 305 females, seen in the STD out-patient clinic.Sixty six males/6.5%/ were homosexuals or bisexuals.Methods.The HIV antibodies were tested by the EIA method,and positive tests were confirmed by the Western-blot technique.Results.The HIV antibodies were found in 15 male patients and 2 females i.e.13% of all individuals studied.Thirteen of men were homosexuals or bisexuals,which represents 19.[illegible]%of patients with such a sexual behaviour one of them was also IV drug addict.Two of 3 heterosexuals cases with positive HIV test were IV drug users.Seven of 13 of HIV-positive homosexuals/bisexuals/53.[illegible]%/ had syphilis recently or in anamnesis,whereas among all homosexuals/bisexuals studied there were 42.4% of cases with history of syphilis.The frequency of HIV infection in homosexual STD out-patients is markedly higher than in heterosexual STD out-patients/0.4%/as well as in another group of homosexuals without STD /2.[illegible]%/.
Conclusion.Patients of the STD out-patient clinic represent high risk group of HIV infection,predominantly homosexuals with diagnosis of syphilis. These patients should be tested for the presence of HIV antibodies.

M.A.P.70 ANALYSIS OF TRENDS OVER TIME IN CLIENT CHARACTERISTICS AT MINNESOTA (MN) HIV-1 ANTIBODY COUNSELING AND TESTING SITES

Danila, Richard*; Shultz J*; Osterholm M*; Henry K***; Simpson M**; MacDonald K*. *MN Dept. of Health, **Hennepin County Community Health Dept., Minneapolis; ***St. Paul Division of Public Health, St. Paul; MN, USA.

Objective. To evaluate the role of Minnesota HIV-1 antibody counseling and testing site programs (CTS) in HIV-1 transmission prevention efforts.
Methods. CTS client demographic and risk factor data were analyzed for 18,483 CTS clients with HIV-1 serology from 7/85-6/88.
Results. The highest seroprevalence rates were in male homosexual/bisexual intravenous drug users (37 of 145; 26%) and homosexual/bisexual men (705 of 5,310; 13%). A significant decrease in seroprevalence for all clients was noted from 14.3% for the first six months of operation to 3.2% for the last six months ($p<0.001$). This corresponds to changes in client characteristics over time: 1) the number and proportion of female first-time clients who were at low risk for HIV-1 infection increased ($p<0.001$); 2) the number and proportion of homosexual/bisexual males decreased and correspondingly the number and proportion of low-risk heterosexual males increased ($p<0.001$); 3) for homosexual/bisexual males, a significant decline in HIV-1 antibody prevalence over time was noted ($p<0.05$).
Conclusions. These data indicate that CTS programs in Minnesota have progressively served fewer clients at high risk for HIV-1 infection over time. Outreach programs that identify and serve persons at highest risk for HIV-1 infection may be a more effective use of limited public health resources.

M.A.P.71 BLIND HIV-AB AND SYPHILIS-AB SEROPREVALENCE SURVEY IN NEW YORK STATE STD CLINICS

DiFerdinando, George Jr.; Arther, K.; Hipp,S ; Murphy,D.
New York State (NYS) Department of Health, Albany, NY, USA.

Objective. To monitor over time the HIV and syphilis seroprevalence among STD clients in all regions of NYS, excluding NYC.
Methods. Sera of clients receiving syphilis testing (RPR, FTA) at 19 STD clinics in 8 NYS counties during 1988 were tested anonymously for HIV (ELISA, WB). Clients were excluded if they had been tested within the previous 90 day period.
Results. All sites had a substantial percentage of clients with HIV-ab (1.14 to 3.17%) and syphilis-ab (1.64 to 16.0%) positivity. Of 9011 clients, 179 (1.99%) had HIV-ab+ sera; quarterly period prevalence did not increase over time. HIV-ab was higher in males (139/6198, 2.24%) than females (37/2731, 1.35%) ($p<.001$); Hispanics (15/352, 5.77%) than either white (73/3370, 2.17%) or black non-Hispanics (88/5166, 1.70%); and increased with age, from 0.34%, ages 13-19; 1.8%, 20-29; 3.0%, 30-39; to 4.67% in those 40-49; 6.65% of those 50 or older were HIV-ab+. (test for linear trend, p=.0026). Of 8816 with results recorded, 334 (3.79%) had sera RPR+ and FTA+ for syphilis-ab. Overall, those syphilis-ab+ were 3.4 times more likely to have HIV-ab than those without syphilis-ab (5.99 vs. 1.82%, $p<.001$). Among counties, however, the association between HIV-ab and syphilis-ab varied greatly (odds ratios ranged from 0.56 to 15.3).
Conclusion. The HIV epidemic has spread throughout NYS in the STD clinic population. Although HIV-ab status is strongly associated with sero-evidence of current or previous syphilis infection, this association varies widely between clinic location, and those without evidence of syphilis-ab still have a substantial rate of HIV-ab positivity.

M.A.P.72 HIV-1 INFECTION IN PERSONS ATTENDING SEXUALLY TRANSMITTED DISEASE (STD) CLINICS IN MINNESOTA (MN)

Danila, Richard*; Henry K***; Simpson M**; Osterholm M*; MacDonald K*. *MN Dept. of Health, **Hennepin County Community Health Dept., Minneapolis; ***St. Paul Div. of Public Health, St. Paul; MN, USA.

Objective. To determine HIV-1 seroprevalence and risk factors associated with infection in persons attending STD clinics in Minnesota.
Methods. 1094 patients attending two STD clinics from 4/1/88-11/1/88 were systematically selected; participants were interviewed for HIV-1 infection risks and had blood drawn for HIV-1, syphilis, and hepatitis B serology.
Results. Questionnaire and serology data were completed for 932/1094(85%) participants. HIV-1 infection was associated with male-to-male sex ($p<0.001$), and among homosexual/bisexual males, receptive anal intercourse ($p<0.05$). HIV-1 race-specific rates were: white 1.3% (7/529); black 1.1% (4/352); Hispanic 6.3% (1/16); other 0.0% (0/35).

HIV-1 Seroprevalence by Risk Factors

	Male	Female
Risk Category	HIV-1 Pos./Total (%)	HIV-1 Pos./Total (%)
Homosexual/bisexual	9/70 (12.9)	-
IV drug user (IVDU)	1/52 (1.9)	0/17 (0.0)
Homo./bi./IVDU	1/7 (14.3)	-
Heterosexual	0/561 (0.0)	1/225 (0.4)

Conclusions. In Minnesota, HIV-1 infection in STD patients is primarily limited to those with a history of male-to-male sex or IV drug use. Thus, in low prevalence areas, HIV-1 antibody testing should be targeted to STD patients known to be at highest risk.

M.A.P.74 HIV SEROPREVALENCE IN SEXUALLY TRANSMITTED DISEASE CLINICS IN LOS ANGELES COUNTY

Ford, Wesley L.*, Rose, T.*, Kerndt, P.*, Onorato, I.**, Waterman, S.*
*Los Angeles County Department of Health Services, Los Angeles, California, **Centers for Disease Control, Atlanta, Georgia, USA

Objective. To estimate the seroprevalence of human immunodeficiency virus (HIV) among patients attending sexually transmitted disease (STD) clinics in Los Angeles County (LAC).
Methods. Between July and December 1988, consecutive attendees at 4 public STD clinics were screened for HIV Ab. Repeat ELISA positives were confirmed by the immunofluorescent antibody and Western Blot. HIV Ab results were linked without personal identifiers to self-reported demographic and risk factor information.
Results. Of the 2,578 STD patients tested, 2.9% (76) were confirmed HIV Ab positive; the rates were 3.8% (68/1,796) in men, and 1.0% (8/782) in women. The infection rate among Hispanics was 4.5% (32/708); whites 2.5% (5/200); and, blacks 2.4% (39/1608). Hispanics comprised 27.3% of the STD patients tested, but accounted for 42.1% of the seropositives. In contrast, whites and blacks made up 7.8% and 62.6% of the study population, and 6.6% and 51.3% of the seropositives, respectively. Among the 133 persons reporting gay/bisexual behavior, 30.8% (41) were seropositive; 58.5% (24) Hispanic; 34.1% (14) black; and 7.3% (3) white. Seropositivity among heterosexuals was 1.4% (34/2,376); 1.6% (27/1,637) for men, and 0.9% (7/739) for women. The highest rate of infection for heterosexuals was among black men 1.9% (19/1025), and the lowest rate among Hispanic women 0.6% (1/173). Approximately 3.0% of those tested reported recent IV drug use, and 8.0% of those (6/75) were seropositive.
Conclusion. HIV infection among patients at STD clinics in LAC is substantial and warrants routine testing and counseling. The large proportion of minorities attending public STD clinics affords an opportunity to provide AIDS education and risk reduction counseling to high risk members of minority populations.

M.A.P.76 INCIDENCE OF HIV INFECTION IN GAY AND BISEXUAL MEN ATTENDING A COUNSELING AND TESTING SITE OR AN AIDS PREVENTION PROGRAM.

Cohn, David; Koleis, J.; Cooper, S.; Cole, V.; Judson, F. Denver Disease Control Service, Denver,CO, USA.

Objective: To determine incidence of HIV infection in gay and bisexual men (GM) using a counseling and testing site (CTS) or enrolled in an AIDS Prevention longitudinal cohort study (APS).
Methods: GM who attended Denver's voluntary CTS from July, 1985 through December, 1988, and GM enrolled in APS from January, 1987 thru December 1988 (visits every 6 months), were evaluated for incidence of HIV infection, as indicated by seroconversions (SC). Included in the analysis were GM who were seronegative at initial visit and retested at least once. SC was defined as reactive EIA and Western blot antibody tests on a 2nd or later visit.
Results:

	CTS 1985-1986	CTS 1987-1988	APS 1987-1988
No. seroconversions	42	3	4
No. persons observed	396	183	348
No. person-years observed	653.2	151.7	296.5
Mean years/person observed	1.10	0.83	0.85
Rate SC/100 person-years	6.43	1.98	1.35

Conclusion: In Denver, the incidence of HIV infection in GM has decreased significantly between 1985-1986 and 1987-1988. Lower incidence rates were observed both in GM attending a CTS and in GM enrolled in an AIDS prevention program, who likely were self selected for higher motivation for behavioral change.

M.A.P.73 HIV SEROPREVALENCE OF STD CLINICS IN HOUSTON, TEXAS, U.S.A.

Enochs, M.; Falletti, Robert L.; Sullivan, K; Sanchez, D.; Penalaza, D. and Honeycutt H.
Bureau of Epidemiology, Houston Dept. of Health & Human Services, Houston, Texas, U.S.A.

Objective: To present statistical data supporting the growing threat of HIV infection within specific sexually active populations attending an STD clinic.
Methods: A blinded survey was conducted at a large STD clinic servicing a predominantly black area of Houston. All blood samples taken for standard RPR screening were also tested for HIV using the Elisa and Western blot tests. Patients included in the survey were taken consecutively until predetermined gender quotas were attained. No ethnic or age bias was imposed on the selection procedure.
Results: A total of 1,140 samples were collected with 6% HIV positive. Seropositivity is highest in the age groups between 25-34 (23%). Overall, whites are 10% positive with 76 samples tested, blacks are 6% positive with 960 samples tested, Hispanics are 7% positive with 96 samples tested and other ethnic populations are 25% positive with 8 samples taken. Data for heterosexual males (n=543) and females (n=505) indicate whites are 1% positive, blacks are 2% positive and Hispanics are 4% positive. Data for homosexual males (n=92) show whites and blacks to be over 50% positive.
Conclusion: The results of the survey allow us to draw certain conclusions: 1) large sampling from the black population permits us to place greater confidence in the high seropositivity found in that group; 2) homosexual males show a high seropositivity in all age groups and ethnic classifications; 3) samples collected are representative of the clinic population; and 4) persons seeking treatment at Houston STD clinics are showing an overall prevalence of 6% HIV positive.

M.A.P.75 DEVELOPMENT AND FUNDING OF PUBLIC HIV COUNSELING AND TESTING SERVICES IN THE UNITED STATES

Cahill, Kathy*; Bowen, G.*; Kirby, C.*
*Centers for Disease Control (CDC), Atlanta, GA, U.S.A.

Objective: To describe the history and development of public sector funded HIV counseling and testing (CT) services in the U.S. since 1985.
Method: We reviewed quarterly reports from State HIV/AIDS prevention programs and the CDC funding awards of State AIDS prevention cooperative agreements in order to document funding levels for CT, number and location of CT sites, and the number and seropositivity rates of clients served.
Results: Since voluntary HIV antibody counseling and testing services became one of the strategies to prevent HIV infection in 1985, client demand for such services has increased dramatically. In 1985, there were 874 alternate testing sites that tested 79,083 persons nationwide. There were 917 sites and 180,000 tested in 1986, and 1580 sites and 504,000 tested in 1987. Reports show 215,000 persons were tested (annual rate of 860,000) in 1958 sites during July-September of 1988. Funding for risk reduction counseling and testing services increased from $9.8 million in 1985 to $87.5 million in 1989. The rate of seropositivity has decreased from a high of 17.3% in 1985 and 15.0% in 1986, to 5.8% in 1987 and 4.9% in 1988.
Conclusion: Although the original purpose of HIV antibody testing was to protect the blood supply, risk reduction counseling combined with testing has become one of the important intervention strategies available to change sexual and needle sharing behaviors. The increases in funding for these programs in the U.S. has enabled an expansion of CT services to confidential testing facilities in sexually transmitted diseases, women's health and drug treatment facilities in 1988 and 1989.

Other Retroviruses: HIV-2

M.A.P.77 HIV2 INFECTION. SOME CLINICAL AND EPIDEMIOLOGICAL ASPECTS IN PORTUGAL

Botas,Julio;Tavares,L.;Carvalho,C.;Feliciano,H.;Antunes,F. et al. Dep.Inf. Diseases, Hosp. Sta Maria, Lisboa, Portugal.

Objective. To assess the frequence of HIV2 infection in HIV seropositives studied at our Department.
Methods. The charts of 225 HIV seropositives (ELISA and Western blot) were analysed. Tests for HIV2 were performed in HIV1 negatives with disease, sexual partners of HIV2 positives or possibility of infection in Africa.
Results. Nineteen (8.4%), 8 women, 11 men, were HIV1 negative and HIV2 positive. They all denied homosexual contacts or IVDU. Only 2 had received blood transfusions (1 man in 1974, in Portugal, and his wife was also positive; another man in 1968, aged 3, in Africa, who has lived in Portugal ever since). Nine, 5 women, 4 men, were from Guinea-Bisseau. One man had visited several african countries and his wife was also positive. Four men had been in Africa for military service (2 in Guinea, 1968-69 and 71-73; 2 in Angola, 65-66 and 66-68). One woman, prostitute, could not deny sexual contacts with african men. Eight were asymptomatic carriers, 3 ARC and 8 AIDS. Five of them died.
Conclusion. HIV2 infection may be more common outside Africa than generally accepted, should be thougth in HIV1 negatives suspected of AIDS and excluded in blood donors, at least in those who have ever been in Africa.

M.A.P.78 HIV-2 IN ITALY: NO EVIDENCE, YET.

Cadeo G.P.*,Corda L.* ,Pizzocolo G.§,Albertini A.§,Carosi G*

Dept. of Infectious Tropical Diseases, Dept. Chemistry, University of Brescia, Brescia, Italy

Objective. The authors have carried out a wide-scale seroepidemiological survey in the region of Lombardy (Italy) to verify the presence of HIV-2 infection among risk categories.

Methods. 1069 subjects (946 drugs addicts, 80 homosexuals, 25 haemophiliacs and sexual partners) have been screened for HIV-1 and HIV-2 infections (HIV-1 and HIV-2 ELISA and W.B. by Diagnostics Pasteur).

Results. Among the 745 HIV-1 seropositive subjects, 233 sera reacted positively to HIV-2 ELISA test. Confirmation by HIV-2 W.B. has been obtained in 29 cases. When submitted to the specific synthetic peptide assay, the 29 HIV-1/HIV-2 W.B. positive sera strongly reacted to the HIV-1 peptide, while only 2 showed a weak HIV-2 reactivity. The same pattern of serological reactivity has been obtained on the same 29 subjects 10 months later.

Conclusions. Our results don't confirm the existence of HIV-2 among risk cathegories in Italy. This conclusion is also supported by the absence of isolated HIV-2 pattern of seropositivity. The high false positivity rate in ELISA (31,3%) and, to a lesser extent, in W.B. (3,9%) demonstrates the presence of antigenic cross-reactivity among envelope proteins of the two viruses. Specific synthetic assay prooved to be sensitive and specific. The constant presence of weak HIV-2 reactivity in 2 HIV-1+ samples at 10 months interval rules out the possibility of early HIV-2 seroconversion.

M.A.P.79 HUMAN IMMUNODEFICIENCY VIRUS TYPE 2 (HIV-2) SCREENING OF A HIGH RISK POPULATION IN ADDIS ABABA, ETHIOPIA.

Zawdie, D.*; Woody, J.**; Seyoum Ayhunie*; Constantine, N.**; Gebrehiwot, B.*; Messele, T.*; Gizaw, G.***; et al.
* National Research Institute of Health, Addis Ababa, Ethiopia.
** WHO Reference Center for AIDS, Cairo, Egypt.
*** AIDS Prevention and Control Programme, Ministry of Health, Addis Ababa, Ethiopia.

Objective. The major objective was to evaluate a high risk population from Addis Ababa, Ethiopia, for evidence of HIV-2 infection.

Methods. Sera previously collected from 330 prostitutes residing in Addis Ababa were included in the evaluation. Sixty of these had been previously confirmed as HIV-1 reactive sera. A commercial ELISA (Genetic systems) designed to detect antibodies to HIV-2 and HIV-2 Western Blot (Dupont) were used.

Research. Of the 330 sera assayed, 60 were known to be confirmed HIV-1 positives. Thirty-four of these 60 sera were also reactive by the HIV-2 screening ELISA. Assessment of these 34 HIV-2 reactive sera by Western Blot revealed that 10 reacted in a manner that fulfilled the criteria for HIV-2 positivity; all of these were strongly reactive for HIV-1 by Western Blot.

Conclusion. Almost all HIV reactive sera in this population are characteristic of exposure to HIV-1. However, 10 sera reacted with both assays and could represent either dual infection or cross reactions.

M.A.P.80 DETECTION OF ANTIBODIES AGAINST HIV-2 PROTEINS IN HIV-1 SEROPOSITIVE SUBJECTS FROM FRANCE AND GREECE.

FOUNTOULI P.[1], KARMELA A.[1], BERTOLI A.M.[2], APPIAH A.[2], MALLIARAKI-PINETIDOU E.[1], JASMIN C.[2], GEORGOULIAS V.[1,2]

1. AIDS Reference Center of Crete, Venizelion hospital, Greece, 2. INSERM U268, Hopital Paul Brousse, 94804 Villejuif, France

Objectives: To determine the prevalence of HIV-2 infection in HIV-1 seropositive subjects from France and Greece.

Methods: HIV-1 infection was always confirmed by western blot analysis. Antibodies against HIV-2 proteins were detected by western blot and discrimination between HIV-1 and HIV-2 infection was based on the serum reactivity with synthetic peptides homologous to the 583-609 region of gp 41 (pept 39=HIV-1) and the correspondant region of gp36 (pept 42.2.1=HIV-2).

Results: Western blot analysis of the sera revealed a frequent reaction with isolated HIV-2 proteins. However, frequently they reacted with isolated HIV-2 proteins only 7(16%) and 9 (50%) of 44 and 18 sera of French and Greek origin, respectively, displayed antibodies against all HIV-2 proteins. Among the 15 French sera reactive with the gp of HIV-2 only 4(27%) revealed reactive with both the pept 39 and the pept 42.2.1 whereas none of the 9 Greek sera was reactive with the pept 42.2.1. However, HIV-2 infection was confirmed in an asymptomatic Greek blood donor in the absence of HIV-1 infection.

Conclusions: These findings seem to indicate that although double HIV-1/HIV-2 can be observed in a small number of HIV-1 seropositive subjects and HIV-2 is present in Greece, there is still a different transmission rate of this virus in different European countries.

M.A.P.81 HIV-2 IN DRUG ABUSERS OF SPAIN

Vincent Soriano*, J. Tor*, A. Ribera**, R. Muga*, B. Clotet*, J. Martin***, *Infectious Diseases and **Blood Bank Units, Hospital de Badalona "Germans Trias i Pujol", Universitat Autonoma de Barcelona, Barcelona, Spain; ***Laboratoires Clonatec, France.

Infectious Diseases and Blood Bank Units. Hospital de Badalona "Germans Trias i Pujol". Universitat Autònoma de Barcelona.Barcelona, Spain. Laboratoires Clonatec**, France.

Objective. HIV-2 is a new AIDS retrovirus identified in West African patients in 1986. Up now, most world cases of HIV-2 infected individuals came from West Africa. Recently several cases of indigenous HIV-2 infected persons have been reported in Europe, usually among classical risk groups for HIV-1 infection. We report the incidence of HIV-2 infection in drug abusers of Barcelona during five last years.

Methods. We studied 433 Spanish intravenous drug abusers. Serum samples were collected between 1984 and 1988 in the cases seeking medical care for the first time in our hospital. Antibodies to HIV-2 were investigated by ELISA and samples repeatedly reactive were studied by Western blot.

Results

TOTAL	1984	1985	1986	1987	1988
HIV-1 + (257/433;59.3%)	21/37	63/98	61/86	112/180	26/32
HIV-2 + (9/433; 2.1%)					
ELISA 47/433	3	18	9	17	3
WB 9/47	0	0	3	5	1

Conclusion. Our results suggest that HIV-2 infection is present among Spanish drug abusers. All cases had HIV-1 and HIV-2 coinfection.

M.A.P.82 EPIDEMIOLOGY OF AIDS IN PORTUGAL

Ayres,Laura;Pista,A.;Benito-Garcia,A.;Furtado,C.;Avilles,F.
Instituto Nacional de Saúde,Lisboa,Portugal.

Objective. As far as AIDS is concerned Portugal is a country with no parallel in Europe due to the prevalence of HIV-2 infection:of 199 cases notified by 31-12-1988, 19 were due to HIV-2.The purpose of this survey is to present the results of sero-epidemiological studies performed to evaluate the prevalence of HIV infection among groups with risk behaviour.

Methods.A total of 3246 sera from male homosexuals,IVDU,prostitutes,heterosexuals,pregnant women and families of AIDS were tested for HIV-1 and HIV-2 antibodies by ELISA,confirmed by Western Blot.

The Results are as shown:

	HIV-1	HIV-2		HIV-1	HIV-2
Homosexuals(210)	28.5%	1.0%	Pregnant v men(572)	0.5%	0.7%
IVDU (1739)	6.5%	0.2%	African connections(287)	2.4%	9.1%
Prostitutes (214)	1.4%	0.9%	Health workers (115)	0 %	0 %
Heterosexuals (75)	16.0%	21.3%	Family contacts (36)	0 %	0 %

Conclusions.HIV-2 infection is endemic in Portugal,although with less expression than HIV-1. Due to past and present contacts with Africa and the presence in Portugal of immigrant African communities, an epidemiological surveillance of the population is in progress to learn the natural history of HIV infection and evaluate the role of co-factors in the infection (STD, behaviour in terms of sex or drug use,other viral infection,etc.)

M.A.P.83 AIDS CAUSED BY HIV-2 IN SOUTHERN AFRICA

Lyons Susan F*; McGillivray G*; Schoub BD*; Smith AN*; Clausen L**.
*Medical Research Council AIDS Virus Research Unit, National Institute for Virology, Department of Virology, University of the Witwatersrand and **Chamber of Mines, Johannesburg, South Africa.

The RAPID ELAVIA MIXT ELISA, a first generation ELISA designed to detect antibodies to both HIV-1 and HIV-2, was introduced into our routine HIV screening laboratory in June 1988. Between June and December, 1593 routine sera were received. Sera repeatedly reactive on the RAPID ELAVIA MIXT assay were further evaluated using indivual ELISAs for HIV-1 and HIV-2 (ELAVIA I or ELAVIA II respectively). Three sera, reactive in the RAPID ELAVIA MIXT assay, were unreactive in the ELAVIA I but reactive in the ELAVIA II ELISA. Western blotting, using the DuPont HIV-2 IgG Blot, revealed reactivity against core and envelope components of HIV-2.

Two of the HIV-2 positive sera were from black Malawian males with symptoms suggestive of HIV infection. One patient had presented with weight loss and neurological symptoms while the second was a patient with miliary tuberculosis that was unresponsive to standard tuberculosis therapy. Blood drawn from the second patient 16 days before he died showed decreasing reactivity with the core protein p26 and loss of reactivity to the glycoprotein gp41. The third specimen was from a black Mozambican male who also presented with tuberculosis that did not respond to therapy. The patient developed Kaposi's and died after refusing further treatment.

Our results demonstrate that HIV-2 has been introduced into Southern Africa and highlight the requirement for sensitive screening assays capable of detecting antibodies to both HIV-1 and HIV-2.

M.A.P.84

HIV 2 INFECTION IN FEMALE AND MALE BRAZILIAN PROSTITUTE GROUPS

Santos-Ferreira, M. O.°, Mazza, C.°°, Lourenço, M. H.°, Focaccia, R.°°, Veronesi, R.°°
° Fac. Farmacy, Univ. de Lisbon, Portugal. °° Faculty of Medicine, Univ. São Paulo, Brasil

Objective: The identification of the second type of human immunodeficiency virus designated HIV 2 in patients originatig from West Africa with the acquired immunodeficiency syndrome opened a new area of seroepidemiological investigation. Therefore we studied the presence of HIV 2 infection in Brazil.
Subjects and methods: The presence of specific HIV 2 antibodies was investigated in 173 sera obtained from individuals belonging to a risk group: 73 male homosexuals of a cohort of travestites (professional prostitutes) with activity in São Paulo, Brazil; 100 women prostitutes with activity in Santos, Brazil. Sera were tested for HIV antibody by ELISA. Repeated positive ELISA results were confirmed by indirect immunofluorescence assay and Western-blot. Sera giving cross reactivity at the level of HIV 1 and HIV 2 large glycoproteines were further tested for reactivity against a peptide corresponding to the dominant epitope of transmembrane protein (HIV 1 "gp41" glycoprotein and HIV 2 "gp36" glycoprotein).
Results: The number of their partners varied between 1 (minimum) and plus 100 (maximum) partners a week. The average number of partners a week was 27 (standard deviation - 21.1). All the individuals had been practising their activity for at least one year before the study. In the cohort of travestites we found 22/73 (30.0%) seropositives to HIV 1 and 3/73 (4.1%) seropositives to HIV 2. Seropositivity for HIV 1 and HIV 2 was seen in five men (6.8%). In the group of women prostitutes we found 10/100 (10%) seropositives to HIV 1 and 2/100 (2.0%) seropositives to HIV 2. Seropositivity for HIV 1 and HIV 2 was seen in one women (1.0%).
Conclusion: These brazilian cases confirm the presence of HIV 2 in this country.

M.A.P.85

EFFICACITE DANS LE DEPISTAGE DES SERUMS HIV2

Couroucé Anne-Marie et le groupe de travail Rétrovirus de la Société Nationale de Transfusion Sanguine - Paris, France

Objectif : Analyser le gain obtenu dans le dépistage des sérums HIV2 par des trousses mixtes (HIV1 + HIV2) par rapport aux trousses HIV1
Méthodes : 35 sérums HIV2 (dont 11 dons de sang *) provenant de sujets résidant en France ont été étudiés parallèlement avec 2 trousses Abbott (HIV1 recombinant = A1 et Combo HIV1+ HIV2 = A2) 2 trousses Du Pont de Nemours (Env 9 version 1 = D1 et Env9 version 2 = D2) et 2 trousses Diagnostics Pasteur (Elavia 1 = P1 et Elavia mixte = P2)
Resultats : 28 sérums ont fourni un résultat positif avec les 6 trousses. Les 7 sérums donnant un résultat négatif avec au moins 1 trousse HIV1(A1,D1 ou P1) ont tous été reconnus par les trousses HIV1+HIV2 (A2etP2) ou la trousse version 2 (D2). Les résultats de ces 7 sérums sont fournis ci-dessous (Ech/Seuil).

	A1	A2	D1	D2	P1	P2
26 PN*	0.5	>6	1.5	4.1	0.6	>6
35 MJ	1.4	5.0	0.4	>5	1.3	>6
51 GA	0.6	>6	0.5	>5	1.1	>6
5 GRM*	3.3	>6	0.4	>5	4.0	>6
12 MJ	1.5	>6	0.2	>5	3.0	>6
52 CB	2.5	>6	3.7	>5	0.8	>6
LEG	0.3	4.8	0.2	2.5	0.2	>6

Conclusion : Bien que ces 3 trousses HIV1 détectent de 81 à 86 % de sérums HIV2, l'utilisation en transfusion de trousses de dépistage reconnaissant la totalité des HIV2, à condition qu'elles aient une excellente sensibilité HIV1 et une bonne spécificité, est très souhaitable.

M.A.P.86

PREVALENCE OF HIV-1 AND HIV-2 ANTIBODIES IN INDIVIDUALS ATTENDING A CLINIC FOR S.T.D.. A TWO YEAR FOLLOW UP.

Cardoso. J.*, Avillez F.**, Santo I.*, Pista A.**, Ayres Laura **.

*Lisbon Regional Health Administration, Lisbon, Portugal.
**National Institute of Health, Lisbon, Portugal.

There is in Portugal a population with great contact both in the past and at present with individuals from African countries.
For this reason we decided to determine, during a period of about two years the antibodies to HIV-1 and HIV-2 in individuals attending a clinic for STD in Lisbon.
During this period we tested 1253 sera (640 males and 613 females).
We found 32 seropositive for HIV (20 males and 12 females).
Eight individuals were seropositive for HIV-2 (2 males and 6 females) and 24 were seropositive for HIV-1 (18 males and 6 females).
In the male seropositive group there are 6 homosexuals, 6 bisexuals and 8 heterosexuals. Among the seropositive females 11 are prostitutes (of a total of about 350 prostitutes followed) and one is an IVDU.
We conclude that HIV-1 and HIV-2 are present in all the groups.
The studies are in progress in order to have a better knowledge of the problem and also the role of some of this infected people in the heterosexual transmission of infection specially as sexual behaviour is concerned.

Progression : marqueurs de laboratoire et cofacteurs
Progression: Laboratory Markers and Cofactors

M.A.P.87

THE LEVEL OF EPSTEIN-BARR VIRUS EXCRETION IS A PREDICTOR OF DISEASE PROGRESSION IN HIV INFECTION.

Diaz-Mitoma, Francisco; Ruiz, A.; Houston,S.; Romanowski,B.; Preiksaitis, J.: and Tyrrell, D.L.J. University of Alberta, Edmonton, Alberta, Canada

Objective. To analyze the relationship between HIV and EBV infections in a cohort of homosexual men.
Methods. Twenty seven HIV-seropositive and 25 HIV-seronegative homosexual and 52 age-matched heterosexual men were studied. Patients were classified according to the CDC criteria for HIV infection. Individuals in group IV were excluded. Patients were evaluated at 0, 2, 6, 12 and 18 to 24 months. EBV and human (hDNA) DNA's were measured in oropharyngeal washings by dot hybridization and densitometry scanning.
Results. Twelve individuals among the 27 HIV-seropositive had low level (<0.7ng of EBV DNA /μg of hDNA) and 3 had undetectable levels of EBV DNA in mouth washings. None of these subjects demonstrated progression of the HIV infection. In comparison, 12 of the 27 HIV-seropositive men had high levels of EBV DNA excretion (≥ 0.7ng/μg hDNA) and 9 demonstrated progression of disease. At the 18 month followup, of 16 asymptomatic HIV seropositive (group II), 3 progressed to group III and 1 to group IV. Of the 11 group III individuals, 5 developed AIDS. Patients who progressed to group III or IV disease had significantly higher levels of EBV excretion (2.27 ± 2.0 ng/μg hDNA) on initial assessment than HIV-seropositive individuals in whom progression of HIV-infection was not demonstrated (0.34 ±.30 ng/μg hDNA, p=<0.0015).
Conclusion. The positive predictive value of high levels of EBV excretion for progression of HIV infection was 75% at 18 months. High EBV excretion was found in 3 of 25 HIV-seronegative and 4 of 52 heterosexual men. This would suggest that high EBV excretion is not solely on the basis of HIV-induced immunosuppression.

M.A.P.88

PROGNOSTIC VALUE OF ANEMIA IN ASYMPTOMATIC HIV-POSITIVE MEN

Battegay, Manuel; Ledergerber, B.; Brühwiler, J.; Siegenthaler, W. and Lüthy, R.; Department of Medicine, University Hospital Zurich, Switzerland

Objective: To study the prognostic value of anemia in 225 asymptomatic HIV-positive men and to assess the correlation to thrombocytopenia.
Methods: We measured hemoglobin (Hb) and platelets (plt) in 225 consecutive asymptomatic homo- or bisexual men with at least two visits and more than one month follow-up. The progression from early stages (CDC II and III) to advanced stages (ARC and AIDS) was analysed for patients with anemia (Hb < 14.0 g/dl) and without anemia using product limit estimators and the Cox proportional hazard regression model.
Results: The median observation time of the cohort was 617 days (range 28 - 1636). Anemia developed in 8% of the patients after a median observation time of 332 days (range 1 - 1240) and did not correlate with plt counts. The following table summarizes the results obtained:

	with anemia		without anemia	
Number	18	(8%)	207	(92%)
Median age (years)	44	(26-53)	36	(19-67)
Mean hemoglobin [g/dl]	13.3	(SD 0.5)	15.7	(SD 0.87)
Mean platelets [10^9/l]	233	(SD 83.7)	245	(SD 66)
Progression to ARC/AIDS	8	(44.4%)	26	(12.6%)

The one year progression rate after developing anemia was 30% (95% ci. 13-57%), for non anemic patients 5.5% (3-10%). The relative risk for progression to advanced stages was 4.8 (p=0.001) for a 20% decrease in hemoglobin and 1.5 (p<0.001) for a 20% decrease in platelets.
Conclusion: Anemia and thrombocytopenia both have an independent prognostic significance in asymptomatic homo- and bisexual men.

M.A.P.89

AGE AT TIME OF HIV INFECTION AS COFACTOR OF PROGRESSION TO ADVANCED IMMUNE DYSFUNCTION AND AIDS

Hatzakis,Angelos*;Mandalaki,T.**;Katsouyanni,K.*;Karafoulidou,A.**;Polychronaki,H.**;Gialeraki,A.**;Economidou,J.***;Trichopoulos,D.*.*Athens Univ.Medical School,Athens,Greece,**Laikon Hosp.,Athens,Greece,***Evangelismos Hosp.,Athens,Greece.

Objective. To study whether age at the time of acquisition of HIV infection is associated with progression of HIV infection and to determine the pattern of the age dependency.
Methods. 122 HIV(+) hemophiliacs,included in follow up studies since 1980,seroconverted between 1980-1985.Seroconvercion was documented by ELISA and WB or RIP. By November 1988,30 cases have progressed to advanced immune dysfunction (AIMD) (T4<200μl) and 20 cases of AIDS or ARC2 (ARC plus T4<200μl) have been diagnosed.
Results and Conclusions. Age was a statistically significant variable for AIMD or AIDS/ARC2 progression in univariate and multivariate analyses (allowing for duration of HIV positivity and controlling for the amount of infused factor VIII). However, the age effect, estimated by Cox model,was limited to the age above 50 (RR=5.5, p=0.006,95% CI 1.6-18.3)

TABLE

Incidence	Age(years) <19	20-29	30-39	40-49	>50
Cum. Incid. AIMD(%)	34.4	22.9	19.0	20.0	50.0
Incid.Rate AIDS/ARC2 (cases/1000pers-mo)	2.7	3.1	2.3	3.3	13.9
Rate Ratio of AIDS/ARC2	1.0	1.2	1.1	0.9	5.5

M.A.P.90 HISTORY OF SYPHILIS AS A COFACTOR FOR THE EXPRESSION OF HIV INFECTION

Joseph R. Berger*/**, M. McCarthy*, L. Resnick****, M. A. Fletcher**, N. Klimas**, L. La Voie***, et al., *Dept. of Neurology, **Internal Medicine, and ***Pediatrics, University of Miami School of Medicine, Miami; ****Department of Dermatology, Mt. Sinai Medical Center, Miami, FL, U.S.A.

Thirty-eight of 109 (34.9%) subjects enrolled in a study of the neurological consequences of HIV infection had a history of prior syphilis. A positive history of syphilis was noted in 53.3% of symptomatic HIV seropositives in comparison to 37.3% of asymptomatic HIV seropositives and 10.5% of risk group-matched controls. Analysis of the asymptomatic HIV seropositive group revealed that a history of syphilis and/or a positive serum FTA-ABS correlated with the presence of serum p24 antigen [>20 pcgm/ml] (P=0.029). Only 1/47 (2.1%) with a negative history for syphilis expressed p24 Ag in the serum in comparison to 7/38 (18.4%) with a positive history. There was a suggestion of correlation between T4 lymphocyte count <200 and syphilis infection, as determined by either history or the presence of a positive serum FTA-ABS; however it did not reach statistical significance.

Although syphilis, like other venereal diseases that result in genital ulceration, has been established to promote the acquisition of HIV infection, our findings suggest that it may also be a cofactor for the expression of HIV infection.

Supported by National Institute of Neurological Diseases and Strokes Program Project P01-NS23569.

M.A.P.91 EFFECT OF PREVIOUS KNOWLEDGE OF HIV POSITIVITY ON SURVIVAL OF AIDS PATIENTS IN NORWAY.

Anne Eskild*, Per Magnus*, Øyvind Nilsen**
*Dep. of Epidemiology, **Dep of Infectious Disease Control,
National Institute of Public Health, Oslo, Norway.

Objectives. To study the effect on survival of AIDS patients of three background factors obtained at the time of diagnosis.

Methods. Cases of AIDS are, in Norway, reported to the National Institute of Public Health. From January 1983 to January 1989, 100 AIDS cases have been notified of whom 67 have died within the same time period. The cumulative AIDS incidence was, by Jan. 1st. 1989, 25 per mill. The average delay in reporting from diagnosis has been 1 month. In a Cox regression model, the following covariables, given on the standardized form of AIDS notification, were used: a) year of diagnosis b) initial AIDS related disease and c) whether HIV positivity was known prior to AIDS diagnosis or not.

Results. The median survival time of all AIDS patients was 9 months. An increased median survival is observed during the observation period; from 5 months before 1986 to 11 months after 1986. In the Cox regression model known HIV positivity is the only covariable significantly associated with increased survival. The not-known HIV positive (n=55) had a median survival of 6.5 months, whereas the known (n=45) had a median survival of 13 months. 60% known HIV positives had PCP as initial AIDS disease. That was true for only 30% of the AIDS cases where seropositivity was not known.

Discussion. The observed increased survival by year of diagnosis may be a due to a combination two factors: earlier diagnosis and earlier treatment.

M.A.P.92 CONTINUED INJECTING DRUG USE AS A COFACTOR FOR PROGRESSION OF HIV.

*Flegg PJ, *Jones ME, *MacCallum LR, **Bird AG, **Whitelaw JM, *Brettle RP. *Infectious Diseases Unit, City Hospital; **Immunology, Royal Infirmary, EDINBURGH, Scotland.

OBJECTIVE: To determine the effect of continued injecting drug use (IDU) as a cofactor for clinical and laboratory progression of HIV infection.
METHODS: Since 1985, 248 intravenous drug users infected in 1983/84 have been evaluated by history, clinical examination and laboratory markers.
Results: 133/248 (53.6%) had continued and 115/248 (46.3%) discontinued injecting drug use. Clinical progression to a CDC category of worse prognostic significance occurred in 49, 28 injectors and 21 ex-users (Ex); the difference was not significant. Laboratory data are available on 41 patients, showing significant differences in rate of T4 cell loss. Mean duration of follow-up until time of progression did not significantly differ (IDM - 10.4 months, Ex 11.8 months, p = 0.5).

Parameter	Mean Change Per Month IDU	Ex	p value
T4 Absolute (per cu mm)	-46.0	-8.7	*0.02
T4 Percent	- 1.1	-0.7	0.52
T4/T8 Ratio	-0.12	-0.06	0.25
IgG (gm/l)	+0.87	+0.24	0.18
IgA (gm/l)	+0.06	+0.01	0.44

CONCLUSION: Continued IDU is associated with a greater rate of loss of T4 cells amongst individuals with IDU related HIV infection indicating it is a significant cofactor for HIV progression.

M.A.P.93 CO-FACTORS AND COHORT EFFECTS IN PROGRESSION TO AIDS AMONG HIV-1 INFECTED HOMOSEXUAL MEN

Stevens, Cladd*; Taylor, P.*; Holford, T.** and Rubinstein, P*. *The New York Blood Center, New York, New York, U.S.A., **Yale University School of Medicine, New Haven, Conn., U.S.A.

Objective. To evaluate possible co-factor effects on the outcome of HIV-1 infection in a cohort of homosexual men in New York City.
Methods. The incidence of diagnosed AIDS and progression to severe immune deficiency (absolute CD4 cells <400) was assessed separately in men who were infected with HIV-1 early in the epidemic (≤1980) compared with those more recently infected (>1980). The effect of prior or subsequent infections with other agents (such as HBV) on progression to AIDS and severe cellular immune deficiency was also assessed.
Results. The rate of progression to AIDS from the time of anti-HIV-1 seroconversion was virtually identical between men with long-term HIV-1 infection and those more recently infected. Neither prior nor subsequent HBV infection had any impact on outcome.
Conclusion. The epidemiologic data from this study provide no support for other in vitro data suggesting HBV or other co-factor influences on progression of HIV-1 infection to clinical AIDS among homosexual men.

M.A.P.94 PROGRESSION OF ARC TO AIDS IN A POPULATION OF DRUG ABUSERS AND CORRELATION WITH CD4 DECREASE AND RISE OF HIV1 ANTIGENAEMIA.

Raise,E;Vannini,V.;Sabbatani,S.;Raise G.;Schiattone,M.L.°;Pulestelli,L°;Cicognani,A.° Dep.Inf.Disease and Clinical Pathology° Maggiore "C.A.Pizzardi"Hospital,Bologna Italy.

Objective.To determine rate of ARC progression into full blown AIDS and prognostic value of immunological factors in drug abusers,in the period 1985 to 1987
Method.The date of progression from HIV1 asymptomatic or LAS to ARC was established in 21 CDC group 4A and 28 CDC group 4C2 patients(pts) and then time and percentage of evolution of ARC into AIDS was monitored prospectively with periodical controls of lymphocyte subsets,by mo. Ab. with EPICS-C cytofluorimeter and of HIV1 antigenaemia(HIV1Ag) by ELISA.

Results

	Six monthly conditional probabilities 6th	12th	18th	24th	30th	36th
ARC CDC group 4A		4.2%				9.5%
ARC CDC group 4C2	28.5%	50%	60.7%	71.4%	75%	78.5%

The different rates of evolution between group 4A and 4C2 appear related to the different absolute number of CD4 in the earlier stages of infection:836-242mm3 in the 4A group v.s.271-327mm3 in the 4C2 group(P)0.05 by T Student test).HIV1 Ag was present in 73% of group 4C2 which progressed to AIDS and only in 33% of pts.remaining stable.Conclusion.Rate of progression from ARC to AIDS appears mainly related to the CD4 depletion during natural history of the infection;HIV1Ag merits further evaluation.

M.A.P.95 PREDICTORS OF PROGRESSION OF HIV-INFECTION

Rizzi Marco, Arici, C., Pirozzi, MG and Maiolo, E
Department of Infectious Diseases, Ospedali Riuniti, Bergamo, Italy

Objective. To determine the rate of progression to AIDS, in relation to total lymphocyte count, CD4 lymphocyte count, and minor opportunistic infections (herpes zoster, salmonella septicemia, pulmonary tuberculosis)
Methods. All HIV-infected patients observed until 31/12/'88 (638 pts, 59% IVDA) were classified with regard to stage of disease, date of previous minor opportunistic infections, total lymphocyte count, CD4 lymphocyte count. Progression to AIDS was evaluated at 6-month intervals.
Results. Number of pts progressed to AIDS and rate (%) pts progressed/total pts. are reported below

month	6		12		18		24		30		36	
gr 2 CDC	1	1.4	2	4.4	2	6.6	0	0	0	0	0	0
gr 3 CDC	4	1.6	5	3.2	4	3.7	4	6.3	5	12.1	5	21.7
gr 4 (exclud. AIDS) CDC	14	12.1	19	20.7	15	30.6	7	22.5	7	38.8	3	42.8
herpes zoster	0	0	2	12.5	1	12.5	0	0	0	0	0	0
salmonella septicemia	1	20	3	75	1	100	2	100	1	100	0	0
pulmonary tuberculosis	2	40	0	0	0	0	0	0	0	0	0	0
total lymphocyte >1500x10⁶/l	0	0	1	0.6	1	0.8	2	2.0	3	6.0	4	10.7
total lymphocyte ≤1500x10⁶/l	8	9.9	13	18.9	11	19.3	10	26.4	6	37	2	28.5
CD4 lymphocyte >400x10⁶/l	1	0.8	1	0.7	0	0	1	1.0	4	9	3	11.5
CD4 lymphocyte ≤400x10⁶/l	13	16.0	13	22.8	9	24.3	7	35	4	50	3	60

Conclusions. Because of the small number of patients with a long follow-up, 30 and 36-months data must be evaluated cautiously. Our overall results are not proposed to describe the natural history of HIV-infection, but we think they may be useful for a rough prognostic evaluation of our patients

M.A.P.96 USE OF SERIAL T4 LYMPHOCYTE COUNTS TO PREDICT TIME TO DEVELOP AIDS IN ANTI- HIV POSITIVE HAEMOPHILIACS

Phillips AN, Lee, Christine, Elford J, Jannossy G, Griffifths PD and Kernoff PBA
Royal Free Hospital and School of Medicine, London, England.

Objective. To describe the use of T4 lymphocyte counts in predicting the time to AIDS in anti-HIV positive patients.
Methods. A series of T4 lymphocyte counts was made on 112 anti-HIV positive patients (111 haemophiliacs, 1 sexual contact) under the care of the Haemophilia Centre at the Royal Free Hospital. The subjects were followed for up to 9 years, with a median of 5 years 1 month.
Results. The median number of T4 counts per patient was 7. In most patients the T4 counts fell with time. When linear regression slopes were fitted, giving a good fit in most cases, the gradients were negative in 78% of subjects. Of the total 21 subjects with AIDS, the analysis was confined to the 13 who were diagnosed with AIDS between 2 consecutive T4 measurements. Probabilities of developing AIDS at or above certain T4 cut-offs were estimated.

T4 count ($x10^9$/l)	.25	.20	.15	.10	.05	.03	.02	.01
Cumulative risk of AIDS	0% *(0/43)*	5% *(2/38)*	13% *(4/32)*	38% *(9/24)*	50% *(10/20)*	68% *(13/19)*	76% *(13/17)*	81% *(13/16)*

Since, on an individual basis, a straight line could be fitted through a series of T4 counts taken over one or two years these results can be used to estimate the risk of a subject developing AIDS within a given time. For example, if it is , .jected that someone's T4 count will fall to .05 in five years time then one would estimate that they have a 50% chance of getting AIDS in the next five years.
Conclusion Serial T4 counts can be used to estimate the time to AIDS in anti-HIV positive patients.

M.A.P.97 LABORATORY MARKERS OF PROGRESSION TO AIDS IN A COHORT OF MALE SEXUAL CONTACTS OF MEN WITH HIV DISEASE

Randall Coates, V. Farewell, J. Raboud, S. Read, D. MacFadden, L. Calzavara, et al., University of Toronto, Toronto, ON, Canada.

Objective:To investigate the relationship between various laboratory markers (routine hematology, immune function tests) and progression to AIDS.
Methods: At recruitment, 143 cohort members were seropositive and 16 seroconverted during followup. All seropositives had routine hematology, quantitative immunoglobulins, T-cell subsets, and blastogenesis studies (PHA, Con A, PWM) conducted at induction or at the time of seroconversion. Cox proportional hazards models were examined for these variables (individually and in combination) while simultaneously adjusting for smoking and drinking status at induction, age, and estimated time from infection to induction into the cohort.
Results: 35 cohort members have progressed to AIDS. The following were significant when markers were examined singly: T4 cell count ($p<0.01$), hemoglobin ($p=0.01$), T4/T8 ratio ($p<0.001$), PHA ($p<0.0001$), Con A ($p<0.01$), PWM ($p<0.001$), and IgA ($p=0.05$). The final model revealed that only PHA ($p<0.01$) and T4/T8 ratios ($p<0.05$) remained independently and significantly associated with risk of progression to AIDS. Estimated time from infection to induction into the cohort was never significant in any of the models.
Conclusions: A depression of the blastogenic response to the mitogen PHA followed by a depression of the T4/T8 ratio were most significantly associated with risk of progression to AIDS in this cohort.

M.A.P.98 T CELL SUBSETS IN A COHORT OF INTRAVENOUS DRUG USERS (IVDUs): INITIAL LEVELS AND STABILITY OVER TIME.

Margolick, Joseph, Muñoz, A., Cohn, S., and Vlahov, D.; The ALIVE Study, Johns Hopkins School of Hygiene and Public Health, Baltimore, MD, USA.

OBJECTIVE: To determine changes over time in T cell subsets in HIV-1 seropositive (SP) and seronegative (SN) IVDUs.
METHODS: 170 IVDUs (88% SP, 12% SN) who completed the first and second semiannual follow-up visits of an ongoing cohort study were evaluated. Proportions (%) and absolute numbers ($\#/mm^3$) of $CD3^+$, $CD4^+$ and $CD8^+$ lymphocytes were determined by 2-color flow cytometry.
RESULTS: (Mean ± SD)

	SP (N = 151)		SN (N = 19)	
	Baseline	Change/6 month	Baseline	Change/6 month
CD4%	28.3 ± 11.6	-0.9 ± 8.9	44.1 ± 10.4	-0.4 ± 9.9
CD4 $\#/mm^3$	603.0 ± 359.7	-59.4 ± 301.0	1118.0 ± 231.3	68.8 ± 655.9
CD8%	49.9 ± 14.7	-2.9 ± 12.2	28.2 ± 9.5	-0.02 ± 7.8
CD8 $\#/mm^3$	1108.0 ± 630.4	-144.8 ± 540.0	832.0 ± 632.0	-61.0 ± 431.0

CONCLUSION: SP IVDUs had significantly lower CD4 and higher CD8 cell counts and proportions than did SN. Neither CD4 nor CD8 levels changed significantly over the six month follow-up period in either SP or SN. CD4 and CD8 levels in SP and SN IVDUs were similar to those in SP and SN homosexual men. The study subjects will be followed to determine the duration of the observed stability of the SP group.

M.A.P.99 PRESENCE OF HIV p24 ANTIGEN STRONGLY PREDICTS DEVELOPMENT OF AIDS

Lang, William*; Anderson, R.**; Shiboski, S.***; Sheppard, H.****; Ascher, M.****; Winkelstein, W.***.
*Children's Hospital, San Francisco, CA, USA; **ViRx, Inc., San Francisco, CA, USA; ***University of California, Berkeley, CA, USA; ****Calif. Public Health Foundation and the Viral & Rickettsial Disease Lab, DHS, Berkeley, CA, USA.

Objective. To correlate prevalent p24 antigen level and other predictors with the subsequent development of AIDS.
Methods. p24 antigen was measured on sera collected in 1985 on a probability sample of 307 HIV seropositive men in the San Francisco Men's Health Study.
Results. Thirty-two percent (13/54) of HIV seropositive men who developed AIDS by 36 months of follow-up versus two percent (6/253) without AIDS were p24 antigen positive. Eight p24 positive men progressed in less than 20 months.

In a Cox proportional hazards model, p24 antigen level is an independent predictor of AIDS development with a relative hazard of 7.2 compared to 5.0 for CD-4 < 400 cells/ul and 2.2 for beta-2 microglobulin > 4 mg/l. The relative hazard increased with increasing p24 antigen level.

p24 antigen positivity is associated with low CD-4 lymphocyte counts (11/89 p24+ with CD-4 < 400 versus 6/244 for CD-4 > 400, p=.007) but not with higher CD-8 (8/173 for CD-8 < 1000 versus 11/134 for CD-8 > 1000, p=.24).
Conclusion. p24 antigen is a strong and independent predictor of subsequent AIDS development. High CD-8 lymphocyte counts do not appear to reduce the prevalence of antigenemia.

M.A.P.100 A COMPARISON OF THE PROGNOSTIC VALUE OF B_2-MICROGLOBULIN, NEOPTERIN, AND SOLUBLE CD8 IN HIV INFECTION

Osmond, Dennis*; Bacchetti, P*; Krampf, W*; Ross, E*; Wizger, E** and Moss, AR*. *University of California, San Francisco/SF General Hospital. **Immunodiagnostic Laboratories. S.F.,CA, USA.

Objective. In addition to CD4 lymphocyte count and HIVp24 antigenemia, B_2-microglobulin, neopterin and soluble CD8 have been reported to predict progression to AIDS in HIV positives. We assessed the relative prognostic strength of these laboratory indicators.
Methods. In a cohort of homosexual men under prospective study, the association of lab·ratory indicators with a subsequent AIDS diagnosis was analyzed on 215 HIV positives with .edian followup of 30 months using a Cox proportional hazards model.
Results. Strong correlations were found between B_2-M and Neopterin (Spearman CorrCoeff=.51), B_2-M and SolCD8 (.61), and Neopterin and SolCD8 (.59). CD4 lymph count correlated with B_2-M 0.36, with neopterin 0.32 and with soluble CD8 0.31. The best multivariate model is the following:

Laboratory indicator	p-value	Relative hazard
B_2-Microglobulin > 5.0	0.001	8.6
B_2-Microglobulin 3.0-5.0	0.008	2.5
CD4 lymphs < $200/mm^3$	<.001	6.0
CD4 lymphs < 25% lymphs	0.008	2.4
HIVp24 antibody qty < 1000	0.02	3.3
HIVp24 antigen positive	0.03	2.1
Qty soluble CD8 > 3500	0.01	2.4

Conclusions. Quantity of serum B_2-M is a stronger prognostic marker than neopterin or soluble CD8 and is the strongest single indicator for AIDS. The best multivariate model for predicting AIDS uses B_2M, CD4 lymph count, and measures of HIVp24 Ag and Ab. Neopterin added no useful information to this model, but quantity of soluble CD8 did contribute some independent predictive power.

M.A.P.101 IS HLA ASSOCIATED WITH PROGRESSION OF HIV-1-INDUCED IMMUNODEFICIENCY?

Richard A. Kaslow*, R. Duquesnoy**, M. Van Raden**, M. Marrari**, L. Kingsley**, R. Detels**, et al., *NIAID, National Institutes of Health, Bethesda, MD; **Multicenter AIDS Cohort Study (MACS), U.S.A.

Objective: To detect any association between presence of HLA antigens and rapid decline in T-helper cell counts or AIDS in men infected with HIV-1.
Methods: Decline in T-helper lymphocyte counts were based on each of 5 semiannual visits of AIDS-free HIV-1-seropositive men selected from the 20% with the most rapid decline (R, N=49) and from the 35% with the slowest decline or rise (S, N=59) by visit 5. Standard methods were used for testing 16 A, 22 B, 2 Bw, 7 C, 10 DR, 3 DQ and the MC1 locus antigens. HLA types were obtained in 24 AIDS cases occurring in R during 4 years of follow-up.
Results: A24 was present in 28.6% of R and 8.5% of S. C5 was found in 24% of R with and in none without AIDS. Means of slopes differed among all R and S and among R with and without those antigens (Table).

Mean Slopes (Change in $CD4^+$ cells/6 months) in Subsets of HLA-typed Men

		No.	S	R		
				All	AIDS	No AIDS
A24	+	19	+43	-156^a	-155	-157^b
	-	89	+59	-124^a	-144	-107^b
Cw5	+	17	+59	-186^c	-186^d	--
	-	96	+49	-126^c	-132^d	-120

^{a,b} $p < 0.05$; ^{c,d} $p < 0.01$ (uncorrected for multiple comparisons)

Conclusion: Although these data show weak associations with two Class I HLA antigens, further study is needed to evaluate the role of HLA antigens in HIV-1-induced immunodeficiency.

M.A.P.102 EVOLUTIVE PROCESS TOWARDS AIDS IN THE MAJORITY OF SYMPTOMLESS HIV-INFECTED SUBJECTS.

Lefrère, Jean-Jacques*; Lambin, P.;* Doinel, C.*; Couroucé,A.M.*.
*Institut National de Transfusion Sanguine, Paris, France.

Objective. To estimate the prognosis of asymptomatic HIV infection.
Methods. 68 asymptomatic (stage II or III CDC) HIV 1 seropositive subjects, with more than 400 CD4 lymphocytes/mm^3 at the onset of the study, were followed-up during a 4 year period. Nine biological markers considered as predictors of AIDS (CD4 lymphocyte count < 400/mm^3, loss of anti-p24 or anti-p18 antibodies, positive p24 antigenemia, serum IgG>17g/l, serum IgA>4g/l, erythrocyte sedimentation rate>25mm in first hour, serum neopterin>10 nmol/l, serum β -2-microglobulin>2.5 mg/l) were annually evaluated.
Results. Number (and percentage) of subjects having biological predictors of AIDS during the study period :

predictors	1985	1986	1987	1988
None	23 (24%)	8 (12%)	4 (6%)	2 (3%)
One	21 (31%)	19 (28%)	10 (15%)	11 (3%)
Two	17 (24%)	23 (34%)	18 (26%)	14 (20%)
Three or more	7 (10%)	18 (26%)	36 (53%)	41 (60%)

The increase of the number of predictors with time is significant (Chi-2 test: p<0.001). At the end of the study period, 6 subjects (8.8%) were AIDS and corresponded to the cases having at the same time the greater number of predictors (5 or more).
Conclusion. These results strongly suggest an evolution towards AIDS in the great majority of symptomless HIV-infected subjects. This constitutes an important argument in favour of antiviral treatment for all HIV-infected subjects.

M.A.P.104 LACK OF ANTIBODIES AGAINST P17 AS PREDICTIVE VALUE FOR AIDS.

Barrera José, Sanchez C, Mallolas J, Planas I, Miró JM, Gatell JM. and Castillo R. Blood Transmitted Diseases Unit. Univ. Barcelona. and Infectious Med. Dept. Hospital Clinic Barcelona. Spain.

Objective. To determine the relationship of p17 antibodies and disease progression in HIV infected people.

Methods.87 HIV-1 seropositive patients were classified according to the CDC and 61 were followed for 22±17 months. The presence of antibodies against p17 was investigated in an optimized Western Blot using H-9 viral lisate (Organon Corporation. USA).

Results. The loss of reactivity against p17 correlated with the clinical stage of patients. The negativity for p17 was obseved in 43% of patients in CDC-2 stage, 91% in CDC-3 stage and 100% in CDC-4 stage. Progression to AIDS was observed in 37% of patients without p17 Ab and in 10% of patients with p17 Ab(p<0,01) The progression to AIDS in p17 Ab- patients was observed in 13% of CDC-2 patients and 40% of CDC-3, and 37% patients in CDC-2 progress to CDC-3.

Conclusion. The loss of reactivity against p17 seems to have predictive value since it has been observed in patients months before developing AIDS and before antigaenemia could be detected.

M.A.P.106 SIGNIFICANCE OF INCREASE OF CD8 LYMPHOCYTES IN ASYMPTOMATIC HIV INFECTION.

Roquin,H.; Doinel, Christian; Lefrère, J.J.; Lambin, P.; Rouger, P.*
*Institut National de Transfusion Sanguine, Paris, France.

Objective. To determine the significance of the increase of CD8 lymphocytes in symptomless HIV-infected subjects.
Methods. 98 asymptomatic (stage II or III CDC) HIV seropositive subjects were followed-up during a 24 month period, with controls at the 1st, 6th and 24th month. All had more than 400 CD4 lymphocytes at the 1st control. Two groups were studied : subjects with an increase of 50 percent or more of CD8, between the 1st and the 6th months (group I : n = 20); and subjects without such an increase (group II : n = 78).
Results. A significant decrease of mean CD4 between the 1st and 24th months was observed in the two groups, but the group I subjects had a mean CD4 count at the 1st and 24th month significantly lower than the group II subjects:

	Group I	Group II	
CD4 at 1st month control	444	612	p < 0.001 (Mann-Whitney test)
CD4 at 24th month control	309	411	p < 0.05
	p<0.01	p<0.001 (Wilcoxon test)	

On the whole, for the subjects of the study, no correlation existed 1) between the 1st and 6th months and the CD4 count at the 24th month, 2) between the increase of CD8 between the 1st and 6th months and the decrease of CD4 between the 1st and 6th months. A negative correlation (r=0.3; p<0.003) existed between the CD4 count at the 1st month and the increase of CD8 between the 1st and the 6th months.
Conclusion. The increase of CD8 appears in HIV-infected subjects when the CD4 count decreases below the threshold value of 400/mm^3 and probably indicates an evolutive process towards AIDS.

M.A.P.103 DIFFERENT COURSES OF HIV INFECTION IN PGL/ARC OF FRANKFURT UNIVERSITY OUTPATIENT CLINIC, INFECTIOLOGY

Brodt R., Kindervater G., Staszewski S., Gottstein A., Kamps B.S., Helm E.B. Universitätsklinik Frankfurt, Zentrum der Inneren Medizin, Infektiologie, Th.-Stern-Kai 7, 6000 Frankfurt/M, FRG

Objective: To describe courses of PGL/ARC significantly differing in temporal and clinical respect.
Methods: 507 pts (99 fem) with HIV infection were followed up by physical examination, immunological, routine lab, and serological tests. Only non-AIDS pts followed up >6mo, and not taking anti-HIV agents, were evaluated.
Results: We found the following value changes per patient per year (average):

Year	n	CD4	CD8	IgG	IgA	Lymphocytes	Leukocytes
1	169	-15	+68	+139	+14	+123	- 79
2	157	-56	+73	+142	+11	+129	- 62
3	116	-57	+75	+126	+16	- 48	- 10
4	53	-68	+13	+ 89	+21	- 60	-275
5	22	-72	-18	+ 60	+ 1	-109	-173

In cases with monitoring period >30mo and CD4 cell count <1/2 of min. normal value, we found significant correlation between increase in LDH, decrease of ht & leukocytes, immunological changes, and clinical findings (oral thrush, weight loss, regression of lymph nodes, frequency & severeness of herpes infections and bact. pneumonias). We could not find any correlation between varying duration & grade of immunodeficiency, and other investigated factors.
Conclusion: Courses of HIV infection vary in pts with initially equal condition. With increasing immunodeficiency, courses get more uniform.

M.A.P.105 PROSPECTIVE EVALUATION OF HIV PROGRESSION IN EDINBURGH INJECTION DRUG USERS

*Flegg PJ, *Cowan FM, *Jones ME, *MacCallum LR, Whitelaw JM, *Brettle RP; *I.D.U., City Hospital; Immunology, Royal Infirmary, EDINBURGH, Scotland.

OBJECTIVE: To assess the clinical and immunological progression of HIV infection in a cohort of synchronously infected injection drug users (IDU).
METHOD: 248 persons (153 male, 95 female) infected with HIV between 1983 and 1984 via injection drug use have been prospectively evaluated for the last 3 years, with 3 monthly clinical and laboratory assessments.
RESULTS: At 5 years post seroconversion, prevalence of symptomatic HIV infection (CDC IV) and AIDS are 22.1% and 3.2% respectively. There have been 1 AIDS related and 10 non-AIDS related deaths.

Months Post	Mean Values (x 10(9)/1)				(gm/1)	CDC IV	AIDS
Serocon.	Lymph	T4	T8	T4/T8	IgA	(total)	(total)
24 - 30	1.99	0.57	0.62	0.92	1.90	4	0
30 - 36	1.60	0.50	0.56	0.95	2.17	10	0
36 - 42	1.91	0.49	0.71	0.86	2.72	19	1
42 - 48	1.84	0.44	0.77	0.63	2.85	29	2
48 - 54	1.73	0.42	0.72	0.61	3.10	41	4
54 - 60	1.52	0.33	0.70	0.53	3.11	55	8

At 54 - 60 months 28% have T4 counts < 0.2 x 10(9)/l.
CONCLUSION: Progression in this cohort of HIV infected IDUs is occurring at a slower rate compared with other risk groups such as San Francisco homosexuals. However, there is a significant non-AIDS mortality as has been reported in New York.

M.A.P.107 CLINICAL AND LABORATORY PROGRESSION OF HIV INFECTION IN BLOOD RECIPIENTS AND THEIR SPOUSES.

Garner,Jane*;Busch,M.*;Samson,S.*;Perkins,H.*;and Ward,J.**.
*Irwin Memorial Blood Centers, San Francisco, California;**Centers for Disease Control, Atlanta, Georgia.U.S.A.

Objective. To compare laboratory test results of HIV-infected transfusion recipients and their spouses with clinical progression to disease.
Methods. Blood samples were tested every six months for up to four years and compared to physical examination for 75 HIV (+) recipients and 26 partners. Tests incl.p24 antigen, p24 antibody, and absolute CD4 cells.
Results. Infected blood recipients progress to clinical disease (ARC,AIDS) in an average of 40 months. A decline in p24 antibody and CD4 cells and the appearance of p24 antigen predicted progression. 4/26 sexual partners of infected recipients are now anti-HIV positive. Although none of the sexual partners are clinically ill, several have laboratory abnormalities.
Conclusion. Infected blood recipients appear to progress to clinical disease at a rate comparable to that of infected individuals from other high risk groups. The rate of heterosexual transmission is low. Laboratory parameters of viral replication and immune dysfunction correlate with, and may predict, disease progression.

M.A.P.108 PREDICTION OF HIV-RELATED CLINICAL OUTCOMES BY USING BETA-2 MICROGLOBULIN (B2), p24 ANTIBODY (Ab), AND ANTIGEN (Ag) IN A COHORT OF INITIALLY ASYMPTOMATIC GAY MEN

Mayer, Kenneth*; Stoddard, A.**, Falk, L.***; Saltzman, S.*; Dawson, G.**; McCusker, J.**, et al.
*Fenway Community Health Center, Boston, MA; Memorial Hospital, Pawtucket, RI; **Univ. of Massachusetts, Amherst, MA; ***Abbott Labs, N. Chicago, IL, USA.

Objective: To assess the clinical utility of p24 Ab, Ag, and B2 in predicting the likelihood of clinical progression and mortality among initially asymptomatic (ASX) HIV+ persons.
Methods: Statistical methods including logistic regression and survival analyses in a cohort of 84 initially ASX HIV+ gay men followed for more than 3 years who are part of a Boston cohort study (N=322) initiated in 1/85. Subjects are screened every 6 months. p24 Ab levels are determined by competitive EIA using a recombinant protein (Abbott).
Results: A higher % of men who were p24 Ag(+) at entry were symptomatic (SX) after 1 year than those who were p24 Ab(-) alone or those with ↑ B2 (30% vs. 19% vs. 16%), but p > .05. After 2 years, the initial presence of p24 Ag on enrollment was the best predictor of the subsequent development of SX (OR=24), but after 3 years, B2 was the best (OR=14.7). Logistic regression analyses suggested that p24 Ag/Ab and B2 are independent predictors of outcomes. Survival at 3 years was .74 for those with normal B2 vs. .41 for those with high B2; it was .76 for those initially p24 Ab(+) and .45 for those who were p24 Ab(-) on enrollment.
Conclusions: p24 antigenemia predicts clinical progression sooner than ↑ B2. Twice as many Ag(+) subjects became SX in 1 year as those with ↑ B2. Survival at 3 years is similar in ASX HIV+ subjects who are p24 Ab(-) or have ↑ B2.

M.A.P.110 FACTORS ASSOCIATED WITH HIV PROGRESSION IN NAIROBI PROSTITUTES.

Holton, Donna*, Cameron, D.W.**, Simonsen, J.N.***, Ndinya-Achola, J.O.****, Ngugi, E.****, Plummer, F.A.*,****.
*University of Manitoba, Winnipeg, Manitoba, Canada, **University of Ottawa, Ottawa, Ontario, Canada, ***Case Western Reserve University, Cleveland, Ohio, U.S.A., ****University of Nairobi, Nairobi, Kenya.

Objective. To determine factors associated with progression of HIV disease in a cohort of HIV seropositive female prostitutes living in Nairobi.
Methods. In February 1985, 595 female prostitutes living in Nairobi were enrolled in a longitudinal cohort study. Continuing recruitment has enrolled a further 382 women. In November 1986, an educational program was introduced which resulted in increased use of condoms. The women attend the clinic for treatment of STDs. They were resurveyed at 6 month intervals for clinical progression of HIV disease. Markov models determined 4 distinct time panels. Women who did not change CDC staging were compared to women who advanced in CDC staging using univariate and multivariate analysis. Factors assessed were age, years prostitute duration, use of oral contraceptives, pregnancy, incidents of genital ulcer disease, episodes of gonorrhoea and use of condoms.
Results. Among the variables evaluated, condom usage correlated with disease progression. Women who used condoms in <50% of their sexual contacts were statistically more likely to advance from CDC stage III to CDC stage IV (p<.05).
Conclusion. In addition to preventing HIV transmission, condom use may also delay HIV progression.

M.A.P.112 NO EVIDENCE FOR RISKFACTORS FOR PROGRESSION OF HIV INFECTION AMONG HOMOSEXUAL MEN

Van Griensven, Godfried JP; De Vroome, EMM; De Wolf, F; Goudsmit, J; Roos, M; Coutinho RA.
AIDS study group Amsterdam, The Netherlands.

Objective. To identify riskfactors for progression of HIV infection.
Methods. Between Oct. 1984 and May 1985 746 homosexual men, 234 HIVab+, entered a cohort study on riskfactors for HIV infection and AIDS. During follow-up until 1988 52 men seroconverted. Subjects are seen every 3 mo. for medical history, physical examination and collection of bloodsamples and psychosocial and behavioral data. The 286 HIVab+ individuals were classified in a high and low risk group for progression to AIDS. High risk was defined as the presence of HIVag or the absence of antibody to HIV core or a no. of T4 cells < 0.5 during three or more subsequential sample sera. For statistical comparison high and low risk subjects were matched at random in time, taking the date of the first high risk bloodsample as a reference.
Results. Of the 234 seropositives 40 (17%) were high risk at entry and 98 (42%) became high risk during the study. From the 52 seroconverters 9 (18%) were high risk immediately after seroconversion and 11 (21%) became high risk later. In bivariate analyses herpes zoster was associated positive with risk status (p<.05) while the level of education was associated negative (p<.01). Multivariate analysis revealed that anogenital receptive intercourse was related to low risk status (p<.05). No relation was found with the use of nitrite, alcohol, tobacco, sex with a person with AIDS, history of STD's, expression of emotions and experience of social support.
Conclusion. After primary infection no riskfactors are found for progression of HIV infection among homosexual men.

M.A.P.109 EVALUATION OF GROUP SPECIFIC COMPONENT AS DETERMINANT OF HIV SUSCEPTIBILITY AND PROGRESSION

Angelos Hatzakis*, T. Mandalaki**, R. Butler***, R. Pflugshaupt***, C. Tsoükala**, K. Katsouyanni*, et al., *Athens University Medical School, Athens, Greece; **Laikon Hospital, Athens, Greece; ***Red Cross Foundation, Bern, Switzerland.

Objective. To study whether Group Specific Component(GC)phenotypes are associated with HIV susceptibility and progression.
Methods. 229 hemophilia patients were included in semiannual follow up studies since 1980. Seroconversions to HIV occured between 1980 and 1985 and were documented by ELISA and WB or RIP assays [122 HIV(+),107 HIV(-)]. By November 1988,20 AIDS or ARC2 (ARC plus T4<200/µl)cases have been diagnosed. The GC phenotypes were tested using isoelectric focusing.
Results and Conclusions. The GC phenotypes are not associated with HIV susceptibility (Table). The GC 2-F phenotype was associated to faster progression to AIDS (The age-adjusted RR by Cox model was 3.97,P=0.041,95% CI 1.06-14.86).

TABLE

		GC phenotypes (%)					
Group	n	2-2	F-F	S-S	2-F	2-S	S-F
HIV(-)	107	9.3	1.9	38.3	3.7	29.9	16.9
Healthy HIV(+)	102	9.8	4.9	33.3	4.9	33.4	13.7
AIDS, ARC2	20	-	-	35.0	15.0	40.0	10.0
Incidence Rate (cases/1000 pers-mo)		-	-	4.1	8.3	4.4	3.0

M.A.P.111 THE NATURAL HISTORY OF HIV INFECTION IN A COHORT OF HOMOSEXUAL AND BISEXUAL MEN: COFACTORS FOR DISEASE PROGRESSION, 1978-1989

Nancy A. Hessol*, L. Barnhart*, P. O'Malley*, A. Lifson*, S. Buchbinder*, L. Doll**, et al., *Department of Public Health, San Francisco, CA; **AIDS Program, Centers for Disease Control, Atlanta, GA, U.S.A.

Objective. To identify possible cofactors for progression of HIV infection in a cohort of homosexual and bisexual men.
Methods. We evaluated 268 HIV-infected homosexual and bisexual men with well approximated seroconversion (SC) dates, from 1977 to 1988, for cofactors for progression of HIV infection to AIDS using both odds ratios and Cox proportional hazard stepwise analyses. Analysis was restricted to those exposures following estimated date of SC. Spearman rank correlation test compared latency time (from HIV SC to AIDS diagnosis) to survival time (from AIDS diagnosis to death) among the 77 men who died of AIDS.
Results. Univariate analysis showed that HIV-infected men who developed AIDS were more likely to report a history of amebiasis, gonorrhea, and herpes simplex, and less likely to report using AZT. Cox multivariate analysis showed significant association with progression to AIDS and history of amebiasis and gonorrhea. Age at SC, race, history of recreational drug use, use of other antivirals and vitamins, and history of other sexually transmitted diseases (STDs) were not statistically associated with progression to either AIDS diagnosis or death. There was no significant correlation between latency time and survival time.
Conclusion. Infection with certain STDs following HIV seroconversion is associated with progression to AIDS. Investigation into cofactors which increase or decrease the likelihood of progression to AIDS is warranted.

M.A.P.113 COFACTORS OF PROGRESSION TO AIDS IN A COHORT OF MALE SEXUAL CONTACTS OF MEN WITH HIV DISEASE

Randall Coates, V. Farewell, J. Raboud, S. Read, D. MacFadden, L. Calzavara, et al., University of Toronto, Toronto, ON, Canada.

Objective: To investigate potential cofactors for progression to AIDS in a cohort of male sexual contacts of men with HIV disease.
Methods: At recruitment, 143 cohort members were seropositive and 16 seroconverted during followup. Data on age, smoking and drinking status, recreational drug use and history of sexually transmitted and other diseases were obtained from interviews at induction into the cohort. Cox proportional hazards models examined the potential effect of recreational drug use and infections one at a time (and then in combination) while simultaneously controlling for age, smoking and drinking status, and either time from first sexual contact with the index case to induction or calendar year of infection.
Results: 35 cohort members developed AIDS while under study. No significant association with risk of progression to AIDS was noted for use of various recreational drugs (singly or in combination), history of specific infections, age, or smoking and drinking status.
Conclusion: We could not demonstrate a significant association of any of the potential cofactors and risk of progression to AIDS. In this analysis, estimated length of time that one has been infected was the only variable associated with risk of progression to AIDS.

Prévention : Politiques et évaluation des programmes

M.A.P.114

VIRUS LEAKAGE THROUGH NATURAL MEMBRANE CONDOMS

Lytle, C.D.; Carney, P.G.; Vohra, S.; W. Howard Cyr and Bockstahler, L.E..
Division of Life Sciences, Center for Devices and Radiological Health, FDA, Rockville, Maryland 20857 USA

Objective. To determine virus leakage from condoms made from processed sheep caecum using two viral probes simultaneously. This study expands on the results presented at the IV International Conference on AIDS.
Methods. A mixture of two viruses, the bacteriophage ΦX174 (@ 4x10 exp 7 pfu/ml) and the human pathogen, herpes simplex virus (@ 1x10 exp 6 pfu/ml), in buffered solution was poured into condoms which were suspended into beakers, also containing buffered solution. Aliquots from the beakers were assayed to measure extent of virus leakage from the condoms.
Results. With one brand of condom, 10 of 24 samples leaked small amounts of ΦX174; with the other brand of condom, 13 of 24 samples gave similar leakage. The extent of leakage varied over two orders of magnitude for both brands of condoms. Of the 23 condoms which leaked the smaller virus ΦX174 (27 nm diameter), two also leaked the larger herpesvirus (120-150 nm diameter).
Conclusion. These data demonstrate that (1) large and small viruses can leak from natural membrane condoms, (2) there is considerable variation from condom to condom in allowing leakage of the viruses, and (3) leakage of a small virus does not necessarily indicate that a larger virus will leak from that particular condom. Some inconsistencies in the published literature are explained by these findings.

M.A.P.115

AIDS STREET NURSES

Rekart, Michael L.; McCarthy, M.; Farrow, C. STD Control, Ministry of Health, Vancouver, British Columbia, Canada.
Objective To report on the framework, implementation and results of a unique AIDS street program.
Methods In January of 1988, the British Columbia Ministry of Health initiated an AIDS/STD outreach program targeting street-involved persons for education and prevention using specially trained community nurses. This staffing direction was taken at the specific request of the street-involved persons and street support groups already active. Strategies include one-to-one information giving, 'on the street' HIV testing and counselling, prevention packages (containing condoms, bleach bottles, instructions for each, phone and beeper numbers), bus passes, taxi credit cards, recognizable backpacks and shoulder bags, referral manuals, and first aid supplies.
Results The 'AIDS Street Nurse' program has been extremely well accepted by street-involved persons and street support groups. In addition to their information and prevention role, the nurses fill a health-worker role which cannot be done by non-medical outreach workers. This role includes testing (drawing blood) and counselling, STD examination and treatment, health advice, CPR and first aid. In the last five (5) months of 1988, the program recorded 2846 interventions, distributed 18,607 condoms and 992 bleach bottles, conducted 34 educational workshops, and tested and counselled 174 street-involved persons.
Conclusion AIDS information and prevention outreach programs directed at street-involved persons can be especially successful when staffed by nurses who can fill a medical as well as educational role.

M.A.P.117

SURVEILLANCE- EDUCATION SANITAIRE DES PROSTITUEES AU SENEGAL

SIBY Tidiane*.THIOR I.*. SANKALE J.L.*. GUEYE A.*.NDOYE I..MBOUP S.*. et Coll.**
***Bactério-Virologie/Université de Dakar. **Clinique MST/IHS Dakar**

OBJECTIF : Sensibiliser une population à activité à risque pour rompre la chaine de transmission du HIV et des autres MST.
METHODES. Au Sénégal, 15 % des prostituées sont porteuses d'Ac anti-HIV contre 0,6% dans la population de contrôle. Au cours des visites sanitaires périodiques instituées grâce à la réglementation de la prostitution. 1700 prostituées ont profité des séances d'éducation et d'information où modes de contamination, manifestations cliniques, moyens de prévention des MST et du SIDA sont débattus.
RESULTATS:De plus en plus, nous notons qu'un climat de prise de conscience commence à se répandre parmi elles (souvent en possession de préservatifs, prélèvements vaginaux pathologiques en régression). Mais, le refus des clients d'user de préservatifs, les raisons d'ordre économique qui les poussent à enfreindre les mesures de prévention, le nombre élevé de prostituees clandestines ... sont autant de facteurs qui rendent cet apprentissage difficile.
CONCLUSION: Une information permanente et soutenue, une stratégie permettant de cibler les clandestines, des préservatifs de qualité, peu onéreux et à portée de main contribueront à diminuer considérablement la dissémination du HIV et des autres MST au SENEGAL.

M.A.P.118

CONTROLE DE QUALITE DES TROUSSES ANTI-HIV COMMERCIALISEES EN FRANCE

North, M.-Louise[1]; Mouillot, L.[1,2]; Couroucé, A.M.[1] et le groupe Rétrovirus[2]

[1] Société Nationale de Transfusion Sanguine, France.
[2] Laboratoire National de la Santé (Dept. de contrôle des réactifs), Paris, France.

Objectif. Contrôler la sensibilité des réactifs de laboratoire destinés au dépistage des anticorps anti-HIV commercialisés en France.
Méthodes. Le contrôle de qualité réglementaire est effectué par le Laboratoire National de la Santé (LNS) qui, depuis le 1.1.88, exige des distributeurs un contrôle de chaque lot de réactif mis sur le marché à l'aide d'un panel de 4 plasmas : trois HIV 1 (dont 1 faiblement positif et 1 avec facteur rhumatoïde) et un négatif. En outre, le groupe Rétrovirus a mis en place depuis le 1.12.88 un contrôle interlaboratoires permanent des trousses à l'aide d'un panel de 10 plasmas : 3 HIV 2, 5 HIV 1 dont 3 débuts de séroconversion et 2 négatifs.
Résultats. 1. Le contrôle LNS a permis une amélioration générale des réactifs (17 réactifs/285 lots). La non conformité d'un lot engage les distributeurs à en informer les utilisateurs.
2. Les résultats préliminaires du contrôle interlaboratoires (9 réactifs, 27 lots, 47 déterminations) figurent dans le tableau.

		HIV 1	HIV 2			HIV 1	HIV 2
Elavia I	D.P.	100 %	100 %	Wellcozyme	Wellcome	100 %	20 %
Rapid'Elavia	D.P.	100 %	100 %	Enzygnost	Behring	11 %	0 %
Vironostika	O.T.	100 %	100 %				
HIV Recomb.	Abbott	100 %	100 %	Sorodia	Miles	100 %	17 %
Env. 9	Du Pont	100 %	33 %	Immunocomb	Ortho	50 %	33 %

Conclusions. Ces contrôles permettent d'augmenter la fiabilité du dépistage des anticorps anti-HIV et ainsi d'améliorer la sécurité transfusionnelle.

M.A.P.119

EVALUATION DE L'INTERET D'UN TEST UTILISANT DES PEPTIDES SYNTHETIQUES (IMMUNOCOMB) POUR LE DIAGNOSTIC SEROLOGIQUE DE L'INFECTION A VIH. Michel ROSENHEIM*, M. Ritterband**, D. Kerouedan*, Y. Schwartz****, P. M'Relé***, M. Gentilini* - *Dpt de Médecine Tropicale et Unité INSERM 313, Hôpital Salpêtrière, 47 Bd de l'Hôpital, 75013 Paris, France. **Orgenics Ltd. BP 360. Yavneh, Israël. ***CHU de Brazzaville, Congo. ****PBS Orgenics. BP 209. Ilkirch, France.

Le principe de l'Immunocomb est celui d'un ELISA en phase solide. Ce test est constitué d'un bac de révélation et d'un "peigne" constitué de 12 "dents" sur chacune desquelles sont fixés 2 épitopes synthétiques de la gp41 et un de la gp120. La durée totale de la manipulation est de 35 à 40 minutes. Nous avons testé trois lots de sérums. Sur le lot 1 (914 sérums provenant de patients européens, 635 positifs en ELISA et en Western blot (WB), 279 négatifs), un seul sérum était discordant, négatif par l'Immunocomb et positif en WB. Sur le lot 2 (273 sérums prélevés au Congo, 113 positifs en ELISA et en WB, 160 négatifs), 13 sérums étaient discordants, positifs en Immunocomb et négatifs en WB. Si l'on rassemble les résultats des 2 lots, la sensibilité est de 99,86% et la spécificité de 97,03%. Sur le lot 3 (57 sérums africains douteux contenant des Ac dirigés contre le core sans Ac anti gp), 54 étaient négatifs en Immunocomb et cinq douteux.
Conclusion. L'Immunocomb est un test fiable, sensible et spécifique, d'utilisation aisée, ne nécessitant qu'une micro-pipette et pouvant particulièrement être utile dans les pays en voie de développement, où il est difficile d'installer la structure lourde d'un laboratoire ELISA en dehors de quelques grands centres.

M.A.P.120

Prévalence régionale du VIH
Regional HIV Prevalence

T.A.P.1

VIRUS HIV-1 CHEZ DES ENFANTS DREPANOCYTAIRES POLYTRANSFUSES A YAOUNDE (CAMEROUN). Tetanye Ekoe; Nyouma E; Ndumbe P. et Kaptue-Noche, L. Centre Universitaire des Sciences de la Santé. Université de Yaoundé, Yaoundé, Cameroun.

Au Cameroun, la prévalence des cas de séropositivité au virus HIV est de l'ordre de 0.5%. Jusqu'à récemment, les transfusions sanguines étaient effectuées sans dépistage des anticorps anti-HIV dans le sang des donneurs.
Objectif. Déterminer la prévalence du virus HIV-1 chez des enfants drépanocytaires polytransfusés de la ville de Yaoundé.
Méthodes. Les sérums de 119 enfants drépanocytaires polytransfusés et de 105 enfants n'ayant jamais été transfusés ont été soumis au test MICROELISA VIRONOSTIKA anti-HTLV III avec, en cas de positivité, confirmation au Western blott (WB). Les résultats ont été analysés par le test du chi-carré.
Résultats. Sur 119 sujets drépanocytaires polytransfusés, 18 se sont avérés positifs au test ELISA et seulement 2 se sont confirmés positifs au WB.

		Pts transfusés n=119		Pts non transfusés n=105		
Ages	No pts.	WB+	%	WB+	%	
6-11 mois	5	0	0	0	0	
1-4 ans	58	1	1.7	0	0	p>0.05
5-9 ans	87	1	1.1	0	0	p>0.05
10-14 ans	63	0	0	0	0	
≥15 ans	1	0	0	0	0	
Total	224	2	1.68	0	0	p>0.05

Conclusion. La prévalence du virus HIV-1 est relativement basse chez les enfants de moins de 15 ans à Yaoundé. Cette étude tendrait à minimiser en 1986 le rôle des transfusions sanguines comme facteur de transmission du virus HIV-1.

T.A.P.3

PREVALENCE OF STD AND HIV INFECTIONS IN RISK GROUPS AND CONTROL POPULATIONS IN VARIOUS REGIONS IN SENEGAL
Van der Veen,Fred*; Ndoye,I*; Mboup,S**; Samb,N*; Fransen,L***; Van de Velde,L****.
*Bureau National MST, Dakar, Sénégal; **Université Sheikh Anta Diop, Dakar, Sénégal; AIDS Task Force,Brussels, Belgium; Projet Pikine, Pikine, Sénégal.

Objective. In order to slow down heterosexual spread of HIV infection in Senegal, a strategy to strengthen the national STD-programme has been developed,guided by operational research. As initial step, a prevalence study of STD and HIV-infection is carried out, in order to obtain baseline information and to stimulate local decision making.
Methods. Six intermediate level laboratories in urban and rural areas throughout the country, were equiped and trained to carry out culture of Gonorrhea, detection of C. Trachomatis, Syphilis and HIV serology. Risk groups (female prostitutes and male STD patients) and a control population (pregnant women) were screened.
Results. Preliminary prevalence data of STD including HIV infection will be presented and proposals for subsequent changes in the STD and AIDS programme, within the economical and organizational constraints of each region will be discussed.
Conclusion. Median level laboratories are capable to collect valuable prevalence information on STD, and HIV infection if adequate logistic and technical support is provided. These data are of crucial importance for national STD and AIDS programmes and facilitates their application due to participation by local staff in planning procedures.

T.A.P.5

TEMPORAL TRENDS OF HIV INFECTION BY RISK INDICATOR IN THE LATIUM REGION,ITALY.
Perucci Carlo A.; Arca' M.; Abeni D.; Chierchini P; Orchi N.; Spadea T; Regional Epidemiologic Unit, Rome, Italy.

Objective. To estimate the incidence of HIV infection by risk category using the data from a general population surveillance system.
Methods. A laboratory-based surveillance system of HIV infection has been active in the Latium region (about 5,000,000 inhab.) since October 1985. Every confirmed anti-HIV seropositivity is anonymously notified to the R.E.U. by blood banks, which screen every donated blood unit, and by laboratories, which test for HIV antibodies subjects referring to the NHS. A file of new notifications has been generated by a record linkage which uses the available individual data as keys. The information on risk indicator available in all the notifications of the same subject, as well as that drawn from the clinical follow-up and the notifications of AIDS cases, has been used to estimate trends of HIV infection by risk category.
Results. By 12/31/1988, 7380 positive test results for adult subjects were reported to R.E.U.,estimated to represent 4952 individuals. Completeness of data on risk indicator increased over time from 60% to 74%. Estimated trends of HIV infection by risk factor and sex are reported.

YEAR		MALES					FEMALES			
		IVDA	HOMO	HETERO	BLOOD	TOTAL	IVDA	HETERO	BLOOD	TOTAL
1986	HIV+	928	175	12	7	1122	388	41	2	483
	%	82.7	15.6	1.1	0.6		80.5	10.1	0.4	
1987	HIV+	1050	158	24	11	1248	348	45	8	443
	%	84.1	12.7	2.0	1.2		78.6	10.2	1.8	
1988 (inc.)	HIV+	658	73	29	15	776	223	53	5	280
	%	84.8	9.4	3.8	1.9		79.5	18.9	1.8	

Conclusions. Features of HIV epidemic in Latium are highlighted. Males/females ratio is < 3; IVDAs represent about 85% of adult HIV+; heterosexual transmission is increasing, incidence among homosexual males decrease. Observations of infection through transfusion must be thoroughly investigated. Cautions in interpreting surveillance data as incidence refer to selection in accessing tests, time lag between infection and 1st notification, completeness and accuracy of the data on risk factor.

T.A.P.2

EPIDEMIOLOGY OF HIV INFECTION IN GREATER TEL AVIV.
Burke, Michael; Vardinon, N; Hasner, A; Hoffman, M and Yust,I.
Clinical Immunology Unit, Tel Aviv Medical Center & Tel Aviv University Sackler School of Medicine, Israel.

Over a two-year period (mid-1986 to mid-1988) we examined over 14,000 subjects for HIV_1 antibody, using the ELISA method (Pasteur). Positive results were confirmed by Western Blot testing. The examinees were divided into the following groups and the percentage of seropositives was estimated: (1) Prisoners - 0.3 %, (2) Prostitutes 0 %, (3) Homosexuals or Bisexuals 17 %, (4) Heterosexuals, divided into three subgroups: (a) Blood bank donors 0.2 %, (b) Drug abusers 6.5 %, (c) Recipients of blood transfusions 0.6 %, (d) Others 0 %. In this series there were no cases of HIV seropositive females. Not all asymptomatic HIV antibody-positive individuals had reversed T_H/T_S ratios, although all symptomatic patients did have this reversal. Within the seropositive subjects, HIV antigen was present in 46 % of cases, but did not appear to correlate with the severity of the clinical course. It is clear that the greatest risk factor in this study was homosexuality/bisexuality, followed by drug abuse. Within the homosexual/bisexual group, number of contacts, number of sexual partners, and contact with partners overseas were additional risk factors. Interestingly, recent arrival from "high risk" countries was not a significant factor in heterosexual transmission, which itself was not an important mode of acquisition of HIV infection in the population tested.

T.A.P.4

THE EXTENT OF HETEROSEXUAL HIV TRANSMISSION IN ENGLAND AND WALES: EVIDENCE FROM SURVEILLANCE DATA
Gill, O. Noel; Porter, J.D.H.; Ellam, G.A.; Clarke, S.E.; Porter, K.; Miller, E. et al.
PHLS Communicable Disease Surveillance Centre, London, United Kingdom.

Objective. To describe the trend in heterosexual HIV transmission.
Methods. Data used: AIDS cases from 1982-Dec 88, laboratory reports of newly confirmed HIV +ve persons from 1985-Dec 88, and from 10 laboratories additional data on persons found HIV -ve, Oct 86-Sept 88.
Results. There were 68 AIDS cases (42 M, 26 F) in heterosexual contacts out of 1898. Of these 13 had partner(s) with major risk factors, 48 were exposed abroad and 7 (5M, 2F) had no evidence of exposure abroad. There were 418 HIV +ve reports (203 M, 207 F, 8 unk) in heterosexual contacts, out of 7974. Of these 80 (8 M, 72 F) had partners with major risk factors, 254 (155 M, 93 F, 6 unk) were exposed abroad, 25 (12 M, 13 F) had no evidence of exposure abroad, and 59 (28 M, 29F, 2 unk) were heterosexual contacts without further information. Four of the 4638 male and 1 of the 6413 female heterosexuals attending STD clinics tested by the 10 laboratories were infected, as were 32 of 718 male and 20 of 374 female heterosexuals who were sexually exposed in Africa.
Conclusion. The number of recognised HIV infections acquired through heterosexual contact, mostly abroad, in England & Wales is increasing. By end 1988, however, heterosexual HIV transmission beyond direct contact with people engaging in major risk behaviours was still at an early stage. Because the sensitivity of current surveillance may be low, a substantial HIV increase in heterosexuals could escape early recognition.

T.A.P.6

HIV SEROLOGY IN ONTARIO 1985-1988
McLaughlin, Bernadette; Major, C.; Bond, V.; Gregory, B.; Strunc, G. Laboratory Services Branch, Ontario Ministry of Health, Toronto, Ontario, Canada.

We summarize 3 years of HIV antibody testing in Ontario, a North American population group neighbour of the United States.
Method. All specimens for the diagnosis of HIV infection for Ontario are tested in our laboratory in duplicate by an EIA screening procedure. All reactive, grey zone and negative sera from high risk, symptomatic individuals are tested by an in-house immuno (Western) blot procedure.
Results. 139,340 specimens were tested; 5,102 individuals were confirmed reactive. Clinical information was given in only 2,888 cases, which presented the following risks: homosexual/bisexual male 2,207 (76.4%), Hemophiliac 151 (5.3%), blood/blood product recipient 97 (3.3%), IV drug users 54 (1.9%), endemic area immigrant/traveller 32 (1.1%), sexual partner of HIV+ person 88 (3.8%), offspring of HIV+ person 14 (0,5%), referred by blood collection agency 19 (0.5%), 2 or more risks 107 (3.7%), no risk 101 (3.5%). Of 4,862 cases providing age and sex information 202 (4.2%) are under 19 years; 3,210 (66%), between 20-39; 190 (3.9%) are female. Over 75% of cases identified were submitted from the greater Metropolitan Toronto area. The number of reactive females is increasing with time as is the number of seroconversions (87), particularly in homosexual men in the 19-39 age group (48). HIV-2 infection was detected in 3 individuals from Western Africa.
Conclusion. Although these are partial results, they seem to indicate some differences in epidemiological patterns from the United States.

T.A.P.7 HIV INFECTION SURVEILLANCE IN POLAND

Jacek Juszczyk*, D. Naruszewicz-Lesiuk**, A. Stapinski***, H. Seyfried****, B. Kalinowska*, *Medical Academy, Poznan; **National Institute of Hygiene, Warsaw; ***Medical Academy, Warsaw; ****Hematology Institute, Warsaw, Poland.

HIV infection surveillance in Poland has gone on since 1985. The highest infection risk groups were investigated first. The first native case of HIV infection in Poland was diagnosed in 1986. Until 1987 and three-quarters of 1988, infection predominated among homosexuals, but from the fourth quarter of 1988, a constantly increasing number of infections among intravenous drug users has been noted. Between 1985 to 1988, over two million people were screened for anti-HIV antibodies, and 111 of them were found positive: 52 homosexuals, 12 drug users, 14 hemophiliacs, and 33 others. AIDS was diagnosed in 5 cases, with fatal course of the disease.

T.A.P.9 The Epidemiological situation of HIV in the Federal Republic of Germany. Results based on mandatory reports of laboratories.

[illegible], Horst-Günter and Habermehl, K.O.
Institute for Clinical and Experimental Virology of the Free University of Berlin,Hindenburgdamm 27 ,1000 Berlin 45, FRG

In the beginning of 1987 our institute started to collect data with formalized mark sense cards of all HIV positive patients diagnosed in all laboratories of the Federal Republic of Germany including West Berlin.On the 1.st of October 1987 this procedure became legal force.

Up to the 31.12.88 78.000 of these formulars have been distributed to approximately 2.000 laboratories.Before these formalized mark sense cards are being processed, each card is checked by a special computer program on 35 plausibilities to reduce wrong information and double reports.

It is asked for the month and year, when the laboratories received the material for testing. To obtain a geographical distribution we use the first two numbers of the zip code of the region where the patient is living.Furthermore of interest is the sex , whether there is a pregnancy,the age in years ,the mode of infection,the reason of testing,the clinical state,the type of material and the type of test.This precautions concerning the personal dates insure a maximum of confidentialness.

Results:Up to the 31st of December 1988 a total of 20215 cases have been reported.There were 3000 female and 12527 male cases.Approximately 40 % of all tests have been made by 6 laboratories. The residual tests were distributed over 224 laboratories.

In 42 % of the patients three tests were performed (One ELISA and two confirmatory tests).

In 36 % we know risk factors of the patients. We found intravenous drug abusers in 44 % and homosexuality in 31 % as the most important mode of infection.

The age distribution shows a maximum for the male and female population between 25 and 34 years .The curve of the age distribution of the homosexuals shows elevated levels in older years.

The curve of the number of the monthley new reported cases between May 1987 and September 88 shows a slight decline We have reason to assume that in reality this decline is steeper, due to double reporting, since the longer the registration is performed the more double reports occur.

At present one can conclude that the number of the new detected of HIV infections in the Federal Republic of Germany is declining. This is only valid for this geographical area and the reported period of time. The further development is still open.

T.A.P.11 ANTI-HIV SEROPREVALENCE IN ADULT RURAL POPULATIONS OF UGANDA AND ITS IMPLICATIONS FOR PREVENTIVE STRATEGIES.

J. R. Ndumu* Jane Frances Kengeya-Kayondo* and A. Amsana** W. Namara**
*Virus Research Institute ENTEBBE - Uganda.
**WHO/ACP ENTEBBE - Uganda.

A nationwide sero-survey to obtain an estimate of the prevalence of HIV positives in the population of Uganda and to gain information about the geographical variations within the country was carried out in 1987/88. This encompassed two different types of stratifications namely urban/rural and purely geographic. The cut off age between adults and children was 15 years. It has been shown that a high concentration of the infection is in urban areas. In some of these, a number of persons in the sexually active age groups have been found to be infected. Although infection is already present in rural areas, the rates have been found to range 0 - 5%. This relatively low rate of infection in rural populations is of paramount significance since 90% of Ugandans population is rural. Gradual and purposeful decentralisation of AIDS control activities in the country is already underway.

T.A.P.8 APPARENT HIGH HIV SEROPREVALENCE AMONG HETEROSEXUAL MEN OF MEXICO CITY.

Magis CL*, Garcia ML*, Bravo E*, Uribe P*, Valdespino JL*, Ornelas G*.
Directorate of Epidemiology, Ministry of Health, Mexico

Objective: To analyze the sociodemographic pattern, sexual practices and risk factors among heterosexual men attending an HIV Detection Center.

Method: A questionnaire and HIV detection test were done in 619 heterosexual men without antecedents of blood transfusion, hemophilia or I.V. drug abuse.

Results: 93% of the men were aged between 15 and 44 years old, 58% were single and 31% had children. All men had sexual relations with women during the last ten years, 85% were sexually active during the last six months. 67% had sexual relations with prostitutes. 98% practiced vaginal coitus with eyaculation and 28% used a condom. 33% practiced anal coitus and only 10% used a condom. 50% practiced fellatio and 17% practiced fisting. 14 % had < 4 heterosexual partners (pt) during their lifetime, 21% (4-8 pt) . 31% > 8 pt. 28% had had sexual contacts with foreign women. 45% declared having modified sexual behavior because of AIDS. 7.9% were seropositive to ELISA and W. Blot. After excluding men with blood trasmission risk factors (tatoos and use of non sterile syringes), the seroprevalence decreased to 7.3%. Seropositivity was associated with: being sexual partner of an HIV positive woman (OR 2.47), STD (OR 1.79), tatoos (OR 4.92) and use of non sterile syringes (OR 6.82).

Conclusions: The high seroprevalence of this group as compared with Mexican male blood donors (0.1%) may be due to: preselection of sujects due to AIDS orientation of the clinic; promiscous practices, work-exposed health personnel, partners of known HIV women and socially hidden homosexuality.

T.A.P.10 SEROEPIDEMIOLOGY OF HIV-INFECTION IN FRANKFURT/FRG

Doerr,H.W.*; Enzensberger,R.*; Staszewski,S.**
University Clinics Frankfurt, *Department of Medical Virology, **Department of Internal Medicine, Frankfurt/West Germany

Since 1985, about 2500 persons with HIV infection have been detected in the region of Frankfurt/FRG. The prevalence of HIV infection increases by 30-50 persons per month. Among them only 4 cases of HIV-2 infection were found until now (December 1988). Epidemiological analysis is restricted by the general acceptance of HIV tests and by varying medical care. Nevertheless, studies comparing age, sex and risk group distribution in AIDS patients and HIV-carriers detected during the last six months indicate a change in infection kinetics. Today the new HIV-carriers are increasingly found among iv drug users and prostitutes. 20% of all recently detected HIV carriers are females. 4.4% of 1000 prostitutes followed-up between 1985-1988 were found HIV positive. The probability of acquiring HIV infection outside the risk groups is still low. HIV infected persons were investigated for the-seroprevalence of antibodies to opportunistic infections. Compared to HIV seronegative healthy persons without risk factors and prostitutes, HIV antibody carriers (asymptomatic, LAS and AIDS patients), presented increasing prevalence and titres of antibodies to HSV 1 and 2, VZV, CMV, EBV (VCA, EBNA), HBV (HBc, HBs), and treponema pallidum. The pattern of antibodies to opportunistic infections may support HIV markers of pathogeniesty (e.g.p24 antigen and antibody).

T.A.P.12 4 YEAR FOLLOW-UP STUDY OF THE HIV INFECTION IN HIGH RISK AND CONTROL GROUPS IN MARTINIQUE (F.W.I.)

Roger Chout*; D.Calmo-Quist**;M.Verdier****; R. Hélénon**; R.Demeulemeester***; F.Denis****.
*Laboratoire de Microbiologie - Hôpital du Lamentin 97232 Martinique **Dispensaire des MST ***Inspection de la santé 97200 Martinique ****Laboratoire de Bactériologie CHU de Limoges France

Objective: To determine the prevalence and the epidemiological pattern of the HIV infection in Martinique we tested differents subjects of high risk and control groups for HIV antibodies from July 1985 to December 1988.

Methods: We tested 18 601 subjects from 15 to 60 years old : 3895 out-patients seen for sexually transmitted diseases (STD) ; 4253 pregnant women (P.W) ; 10453 healthy individuals (H.I.). In all cases sera were tested by ELISA and positive results confirmed by Western Blot Pasteur Diagnostic. So only positive results by Western Blot were finally considered positive.

Results : The prevalence and the male to female ratio (sex ratio) for HIV are shown below.

	1985	1986	1987	1988
	N° Positive/N° Tested(%)			
STD PATIENTS	22/460(4.7)	47/1103(4.2)	52/1207(4.8)	38/1125(3.5)
Homo-bisexuals	11/22(50)	10/33(30)	9/32(28)	9/23(39)
Prostitues	5/15(33)	6/16(37.5)	10/23(43)	5/10(50)
Sex ratio	3.4	1.4	1.1	1.4
H.I.	3/2308(0.13)	8/2503(0.32)	15/2778(0.54)	20/2864(0.7)
Sex ratio	2.0	1.8	1.1	1.8
P.W.	1/1007(0.1)	2/1054(0.2)	5/1103(0.45)	10/1089(0.9)

13 men and 9 women who were positive used intravenous drugs.

Conclusion : The evolution of the prevalence and the sex ratio confirm that the spread of the HIV was from bisexuals to heterosexuals individuals. The increasing rate among pregnant women highlight the need for screening at the first term of the pregnancy. It is of great importance that the staff of the maternity and pediatric service should have a good knowledge of HIV in order to be able to avoid unnecessary worry.

T.A.P.13

ARE MISSIONARIES AT RISK OF AIDS?

Lange, W. Robert*†; Dax, E.*†; Kovacs, R.†; Kreider, S.*; and Frame, J.*‡
* Johns Hopkins Medical Institutions, Baltimore, MD, USA.
† ARC, National Institute on Drug Abuse, Baltimore, MD, USA.
‡ Associated Missions Medical Office, New York, NY, USA

Objective. To ascertain whether Protestant missionaries serving in regions of high AIDS incidence have been at enhanced risk of HIV-1 infection.
Methods. Serum specimens (N=6045) obtained from 3207 Protestant missionaries serving in 57 countries, including 28 African nations, between 1967 and 1984 were assayed for HIV-1 antibodies by ELISA screening and Western Blot (WB) confirmatory testing. A positive WB was defined as one with either band gp41 or p24 in association with either gp120 or gp160.
Results. Seventy sera (1.2 percent) from 51 missionaries (1.6 percent) were ELISA positive; however, none was diagnostic of HIV-1 infection on WB testing. Twenty-two WBs (43 percent) were read as indeterminant, defined as the presence of bands in such a pattern that the criteria for being positive was not met. Band p17 occurred with the greatest frequency (57 percent) followed by p24 (23 percent), either alone or in combination.
Conclusion. The significance of the indeterminant WB results is unclear, but they do not appear to be a consequence of exposure to either HIV-1 or HTLV-I. We conclude that missionary personnel were not at high risk of HIV-1 infection between 1967 and 1984, even when serving in regions of high AIDS endemnicity.

T.A.P.14

HIGH-RISK HETEROSEXUALS: DIFFERENCES BETWEEN PRIVATE AND COMMERCIAL PARTNERS IN SEXUAL BEHAVIOR AND CONDOM USE

Christa Hooykaas*; Van der Pligt, J.**; Van Doornum, G.J.J.*; Van der Linden, M.M.D.* and Coutinho, R.A.*
* Municipal Health Service Amsterdam, Amsterdam, The Netherlands, ** University of Amsterdam, Amsterdam, The Netherlands

Objective. To study prevalence of HIV, sexual behavior and condom use among heterosexuals with multiple partners. Methods. Heterosexuals with no other riskfactors than $\geq$ 5 partners in the preceding 6 months were recruited through a STD-clinic. Blood was taken, and questions were asked about number of partners, frequency of practising sexual techniques and condom use with private and/or commercial partners. Results. In 1988, 193 women (136 prostitutes) and 157 men (99 customers) entered the study. Prostitutes had 115 customers per month, customers visited 8 prostitutes in 4 months. On average, 171 women had 4 and 122 men had 7 private partners in 4 months. Vaginal intercourse was reported often to always by all participants, anal contact was seldom reported. Non-risky sexual techniques were reported more frequently with private than with commercial partners ($p < .05$). Condom use was reported more frequently with commercial than with private partners ($p < .01$), and prostitutes reported using condoms more often than customers ($p < .01$). Prostitutes had in 4 months with more partners (± 40) unprotected vaginal intercourse than customers (± 7), and men and women with private partners only (± 4). None of the participants was HIV positive, but 16% had positive HBV-markers, 5% was TPHA positive and 43% was diagnosed with $\geq$ STD.
Conclusion. Despite frequent condom use, prostitutes and customers are at higher risk for HIV than heterosexuals with multiple private partners only.

T.A.P.15

SEROPREVALENCE OF HIV INFECTION AMONG MIGRANT FARMWORKERS

John P. Narkunas*, K. Castro*, S. Reig**, and Migrant Health Program Collaborative Sites**.
*Centers for Disease Control, Atlanta, GA and **HRSA, Migrant Health Program, Rockville, MD, USA

Objective: To determine the seroprevalence of HIV infection in seasonal and migrant farmworkers attending migrant health centers in the United States.
Methods: A total of 3,150 seasonal and migrant farmworkers were tested for HIV antibody in a blinded manner. Basic demographic data were collected and bloods tested by the EIA and by WB at the CDC.
Results: A total of 15 (.5%) HIV seropositives were detected, of whom, 8 (53%) were female. The racial/ethnic background were: Black 1 (7%), Hispanic 5 (33%) Haitian 8 (53%), and white 1 (7%). The state of residence was as follows: Florida 8 (53%), North Carolina 2 (13%), and 1 each from five other states. Of the 15 HIV seropositive, 11 (73%) were migrant workers and 4 (27%) were seasonal farmworkers.
Conclusions: The prevalence of HIV antibody in this population of seasonal and migrant farmworkers was found to be relatively low (.5%). However, it is interesting to note that 13 (87%) of the seropositive were detected in eastern coastal states where a large number of persons move in a migrant stream which emanates from Florida. This survey suggests that sexually active migrant farmworkers in the eastern coastal states may be at greater risk for HIV infection than migrants in others areas of the U.S. and that appropriate testing, counseling and prevention programs should be directed at this population. Due to difficulties inherent in reaching such a mobile and hard-to-reach group, it will be important to develop innovative outreach programs in order to reach them.

T.A.P.16

PREVALENCE OF HIV-1 INFECTION AMONG COLLEGE STUDENTS.

Kotloff, Karen*; Tacket, C.*; Bridwell M.**; Cowan J.*; Wasserman S.*; Quinn T.***.
*University of Maryland School of Medicine, Baltimore;
**University of Maryland, College Park; ***National Institute of Allergy and Infectious Diseases, Bethesda, Maryland, U.S.A.

Objective: To determine the prevalence of HIV-1 infection and high risk practices among undergraduate college students attending a university located in a metropolitan area with a high prevalence of HIV-1 infection.
Methods: In 1988, undergraduate students attending the University of Maryland at College Park were recruited to participate in a voluntary HIV-1 serosurvey and educational campaign. Each student gave informed consent, completed a questionnaire on risk behaviors, donated a blood sample, and received pre- and post-test counseling. Sera were analyzed by ELISA and western blot for HIV-1 antibody.
Results: A total of 3,449 students volunteered for the survey. All students were between 16-40 years old, 47% were male, and 81% were white, 87% of the students were sexually active (88% of males and 87% of females), with a median of 4 lifetime partners (range 0-200). A history of behavior placing a student at risk for HIV-1 infection was acknowledged by 21% of men and 21% of women, when high risk behaviors were defined as male homosexual intercourse (5% of men), IV drug use (1%), previous sexually transmitted diseases (13%), and heterosexual intercourse with a high risk individual (8%). Despite the high frequency of risk behaviors, the HIV-1 infection rate was only 0.6 per 1000 students, with HIV-1 infections documented in 2 homosexual men, both of whom engaged in other high risk behaviors.
Conclusion: Despite the presence of risk behaviors, the rate of HIV-1 seropositivity among this group of college students was low, and infections were confined to high risk homosexual men.

T.A.P.17

SEROPREVALENCE OF HIV AMONG TRANSVETITES IN THE CITY OF SÃO PAULO

Suleiman,J.*;Suleiman,G.*and Galvão,Paulo Augusto Ayroza*
*Hospital Emilio Ribas, São Paulo, São Paulo,Brazil.

Objective.To define the HIV seroprevalence among transvetites.
Methods.On account of their peculiar characteristics and queer dressing and behaviour transvetites find difficulty in attending regular health care services. In order to minimize this difficulty we move our medical team to their own quarters.There they were clinical and laboratorally studied and provided with educational and psychological help.The tests were made by 2ELISA and confirmed by W.B.
Results.Studies on 37 transvetites,from July to September 1988, have shown a HIV seroprevalence of 62%(23).Of these 5.9%(17) were intravenous cocaine users and 5.4%(2) heroin users.From the 37 only 2 belonged to group IV by the CDC criteria.
Conclusion.Transvetites have an important role in the chain of HIV transmission.Considering that among their clients are married men,this group have a significant potential role in heterosexual and vertical transmission of HIV.

T.A.P.18

DO HOMOSEXUAL MEN EVADE HIV-TESTING?

Valle Sirkka-Liisa* and Sarna S.**
* University Central Hospital, Helsinki, Finland
University of Helsinki, Finland.

Objective. To analyze the change in the sexual preference category of the newly-identified HIV-seropositive individuals in Finland.
Methods. As of Sept. 1985, HIV-testing has been available free-of-charge throughout the country. Anonymous testing is possible in 5 AIDS Support Centers. As of Sept. 1985, HIV infection has been a notifiable disease in Finland requiring mandatory reporting on every HIV case to the National Board of Health. Asymptomatic disease is reported by social security code (SSC) as are gonorrhea, genital Chlamydia infections and hepatitis-B. Symptomatic disease (LAS,ARC,AIDS) is reported by name and SSC. Data is collected on the age, profession and place of residence of the patient as well as on the most likely transmission route of the virus.
Results. As of 1.1.89, there are 241 cases of HIV infection, 41 of whom have AIDS. The distribution of the sexual preference among the annually found HIV cases is the following:

	1983	1984	1985	1986	1987	1988	
HOS	10	14	29	41	33	22	= 149
HES	0	1	5	16	17	20	= 59

Out of the 41 cases of AIDS, 31 (75.6%) have been in homosexual men (HOS). 13 of 17 AIDS cases (76.4%) in 1988 were in HOS. 3/13 had AIDS and 5/13 had ARC when HIV infection was confirmed.
Conclusion. The decrease in the number of newly-identified HIV-seropositive HOS can partly be due to decreased risk-taking, but may also reflect a delay in voluntarily taking the diagnostic test.

T.A.P.19

DIFFUSION DES PRECAUTIONS SEXUELLES ET EVOLUTION DE LA SEROPOSITIVITE DANS LA POPULATION HOMOSEXUELLE FRANCAISE: 1985 - 1988

Pollak, Michael*, Schiltz, Marie-Ange*, Boisson, Pierre.**
*CNRS-GSPM, Paris;**Gai Pied Hebdo, Paris.

Objectif:Suivre la diffusion des précautions sexuelles, et l'évolution du recours au test de dépistage volontaire et de ses et ses resultats dans la population homosexuelle française.
Methodes: Sondage annuel par questionnaire inséré dans une revue homosexuelle diffusée sur tout le territoire (n=1000 en 1985,1550 en 1988),complété par un sondage (n=300) aupres d' homosexuels choisis selon les quotas correspondant à la population masculine.
Resultats: Depuis 1986 le préservatif tend à s' imposer comme mode privilegie de protection contre le VIH. (usage régulier: 1985: 5%; 1988: 39%; usage irrégulier: 1985: -;1986:23%, 1988:29%). Lepréservatif est aujourd' hui bien accepté, y compris dans la tranche d' age des moins de 25%, les plus réticents initialement.Néanmoins de differences subsistent entre Paris et la province, et selon le deg d' education et la categorie socioprofessionnelle. Entre 1986 et 1988 la proportion des homosexuels testés est passée de 33% à 55%, avec une stabilisation du taux de seropositifs à 19%.Les ouvriers sont la seule categorie où ce taux a eu tendance à fortement augmenter (1986: 6%, 1987: 11%, 1988: 31%).
Conclusion: Le retard d' adaptation au risque de contamination obsve dans les classes populaires se traduit rapidement par la progresion de la maladie dans ces groupes.

T.A.P.21

INCIDENCE OF HIV-1 INFECTIONS AMONG HOMOSEXUAL MEN IN DALLAS, TEXAS, 1987-1988.

Haley, Charles E*; Freeman A*, Anderson P*, Petty A*, O'Reilly K**.
*Dallas County Health Department, Dallas, Texas; **Centers for Disease Control, Atlanta, Georgia; USA.

Objective: To estimate the incidence of HIV infections among high risk men in Dallas, Texas.
Methods: Between 6/87 and 12/88, 662 homosexual or bisexual men enrolled in a cohort and were to return every six months. All men completed an anonymous questionnaire linked to test results.
Results: The mean age of the cohort was 33.3 yrs; 92% were white; 87% had never used IV drugs. 64% of the cohort members admitted a history of >10 sexual partners since 1980. 178 (27%) were HIV infected at the first visit. Among the 447 HIV negative men, retention in the cohort is 56% at 6 months and 34% at 12 months. Of the 176 previously negative persons who returned for the 1st 6-month visit, 3 (1.7%) had seroconverted; of the 57 who returned for the second 6-month visit, 1 (1.8%) had seroconverted, for an annual incidence of 3.5%.
Conclusions: The incidence of HIV-1 infections is less than 5% per year among homosexual men in this population.

T.A.P.23

TRENDS IN HIV ANTIBODY POSITIVE ADMISSIONS TO A CONNECTICUT COMMUNITY HOSPITAL

Madden, Gayle and Smith C. St. Francis Hospital and Medical Center, Hartford, Connecticut, USA

Objective. Identify demographic trends in HIV infected (HI) patients admitted to a Connecticut community teaching hospital over 3 years.
Methods. Data compiled on sex, race, risk-group and average length of stay per admission (ALOSPA) in all known HI patients admitted to our 592 bed hospital from 1986 to 1988 were reviewed.
Results. From 1986 to 1988, HI adult patient admissions increased 488% : 1986 - 50, 1987 - 166, 1988 - 294. The ALOSPA for AIDS patients decreased from 18.9 days (d) in 1986 to 13.9 d in 1988, while the ALOSPA for non-AIDS HI patients increased from 7.5d to 10.7d. 170 adult HI patients were admitted in 1988, 70% IVDU and 85% Hispanic (Hsp) or Black (Blk). Similar percentages of IVDU, Hsp and Blk HI patients were seen in 1986 and 1987. From 1986 to 1988, among the HI patients, females (F) increased from 17% to 31% (P<0.1), Hisp F increased from 2% to 11% (P<0.1), and heterosexual risk-group (HRG) patients increased from 0% to 5% (P<0.05). HI pediatric cases increased from 0 in 1986 to 9 in 1988, all were children of IVDU.

Year	Total	Blk	Hsp	IVDU	F	Hsp F	HRG
1986	41	24	10	27	7	1	0
1987	112	59	33	78	23	4	1
1988	170	91	52	119	52	19	9

Conclusions. From 1986 to 1988 the black, hispanic, and IVDU composition of our HI adult admissions remained similar, but there were statistically significant increases in HI F, HI Hsp F, and HI adults with heterosexual contact as their only risk factor.

T.A.P.20

CHANGES IN SEXUAL BEHAVIOR CONNECTED TO STRONG DECLINE IN HIV INCIDENCE AMONG HOMOSEXUAL MEN

Van Griensven, Godfried JP*; De Vroome, EMM**; Goudsmit, J***; Coutinho RA*.
*Municipal Health Service Amsterdam, **State University Utrecht, ***University of Amsterdam, The Netherlands

Objective. Study of the relation between changes in sexual behavior and the incidence of HIV infection among homosexual men.
Methods. Between October 1984 and May 1985 746 homosexual men were entered in a prospective study on HIV infection and AIDS in Amsterdam. From these 234 (31.4%) were HIVab+ at entry. Subjects are seen every 3 months for the collection of bloodsamples. Every 6 months a written questionnaire is completed regarding the sexual lifestyle in the preceding half year.
Results. During follow-up until December 1988 59 seroconversions were seen, 34 in 1985 (incidence 7%), 16 in 1986 (incidence 3.9%), 3 in 1987 (incidence 0.8%) and 6 in 1988 (incidence 1.7%). The cumulative incidence rose from 31.4% in 1984 to 40.1% in 1988. During the study period the mean no. of partners with whom seronegatives practiced anogenital receptive intercourse declined from 3.7 to 0.4. Among seropositives the number with whom anogenital insertive intercourse was practiced declined from 10.6 to 1.4. The majority of subjects restricted anogenital intercourse without a condom to a steady partner. Anogenital intercourse with non steady partners was practiced more frequently by seropositives, but in a majority of cases while condoms were used.
Conclusion. This study shows that it has been possible to bend the course of the HIV epidemic through the modification of sexual behavior. A strong reduction of sexual activity during a long period of time was needed to affect the incidence of HIV infection.

T.A.P.22

PREVALENCE AND SEROCONVERSION FOR HIV INFECTION IN HOMOSEXUAL AND BISEXUAL MEN IN MADRID.

Francisco Bru*, F. Babin*, C. Colomo*, I. Pascual*, M. Rua-Figueroa*, A. Garcia-Saez**, *C.P.S. Centro, Madrid Council, Madrid; **CNM e I. Sanitaria Majadahonda, Madrid, Spain.

OBJECTIVE: To study the changes of prevalence of HIV infection in homosexual and bisexual men who attended the clinic between January 1985 and december 1988. The incidence of seroconversion was also studied in the cases that returned for follow-up.

METHOD: In the first visit information about medical and epidemilogical aspects was recorded and a sample of serum was obtained for HIV test. All the patients recieved health education in a personal and individualized interview. Annual follow-up was offered.

RESULTS: In 625 homo and bisexual men the prevalence of HIV infection was of 16.4%. 148 HIV seronegative initial patiens returned for subsequents controls and among them 14 HIV seroconversions were found. The results are summarized in the following table:

	FIRST HIV TEST			INTERVAL(MONTHS)=X		LAST HIV TEST			ANNUAL SEROCONVERSION
YEAR	N	(+)	(%)	Σx	X̄	N	(+)	(%)	RATE
1985	166	17	10.2	1495	20.8	72	9	12.5	7.2
1986	184	40	21.7	792	18.4	43	3	6.9	4.5
1987	213	33	15.5	427	12.9	33	2	6.0	5.6
1988	65	13	20.0	---	----	--	-	---	---
TOTAL	628	103	16.4	2714	18.3	148	14	9.4	6.2

CONCLUSIONS: In 1986 an increase in HIV seroprevalence was found when compared with 1985 (p<0.01). After 1986 no significant changes were found in HIV seroprevalence. The seroconvertion rate (see table) was similar over the period of time studied in spite of health education activities.

T.A.P.24

HIV SCREENING IN AN URBAN HOSPITAL OUTPATIENT POPULATION

Marmor, Michael*; Krasinski, K.*; Sanchez, M.**; Cohen, H.*; Dubin, N.*; Weiss, L.R.**; et al.
* New York University Medical Center, New York, NY, USA; ** Bellevue Medical Center, NY, NY, USA.

Objective. To ascertain seroprevalence of and risk factors for human immunodeficiency virus (HIV) infection in the general population.
Methods. Patients attending the outpatient clinics at Bellevue Hospital Center, Manhattan, New York City, were offered HIV screening. Male patients who had injected non-prescription drugs at any time since 1/1/77, or who had engaged in sex with other men since this date were asked not to participate. Sera were tested for HIV antibodies via ELISA with Western blot confirmation.
Results. 1119 subjects with no prior indications of HIV infection were interviewed and HIV-tested. After exclusion of 2 subjects with indeterminate HIV serology, seroprevalence was 7.1% (26/368) among men, and 5.9% (44/749) among women. Seroprevalence among heterosexuals without other risk factors was 3.3% (10/305) among males and 2.4% (15/619) among females. Rates were substantially higher among Blacks and Hispanics than among Whites. The data were suggestive of an HIV risk among men associated with sexual contact with prostitutes. Among heterosexual women, the primary risk factor was sex with a male intravenous drug user (IVDU). The most common method of birth control reported to be used by both men and women was "no method." 37% of 74 female IVDUs were HIV seropositive; a primary risk factor was the number of years since last injecting illicit drugs. Logistic regression analysis identified significant risks among all women screened associated with years since last injecting drugs and years since last having sex with a male IVDU; a significant negative interaction between these two terms was found.
Conclusions. Heterosexual HIV transmission has been documented, particularly from male intravenous drug users to non-drug-using women. HIV seropositivity among drug users in the general population may be less than previously reported because of the importance of the number of years since last injection. Mathematical modeling of data obtained from women suggests that intravenous drug use and a history of sex with male IVDUs have not been synergistic in their association with HIV infection.

T.A.P.25

SURVEILLANCE HOSPITALIERE DE L'INFECTION PAR LE VIH A BORDEAUX, FRANCE: TENDANCES EPIDEMIOLOGIQUES, 1985-1988

Chaslerie, A.* ; Dupon, M.** ; Morlat, Philippe** ; Lacoste, D.** ; Pellegrin, J-L.** et le Groupe d'Epidémiologie Clinique du SIDA en Aquitaine**.
* Département d'Informatique Médicale, Université de Bordeaux II, Bordeaux, France.
** Centre Hospitalier Régional Universitaire (CHRU), Bordeaux.

Objectif: Un système de surveillance épidémiologique des sujets infectés par le VIH a été mis en place au CHRU de Bordeaux; il permet d'étudier les caractéristiques régionales de l'épidémie et l'histoire naturelle de la maladie.
Méthode : Les services hospitaliers participants incluent leurs patients séropositifs depuis 1985. A chaque consultation, les données sont recueillies de façon anonyme sur un questionnaire standardisé, puis sont informatisées. Les caractéristiques épidémiologiques suivantes sont enregistrées pour chaque patient: âge, sexe, date du diagnostic sérologique, groupe ou comportement à risque élevé et mode de contamination probable. La classification utilisée est celle des Centers for Disease Control.
Résultats : Au 10 octobre 1988, 648 adultes séropositifs ont été inclus. Le sexe ratio Homme/Femme est de 3:1, l'âge median est de 28,5 ans, et 50% des sujets sont âgés de 20 à 29 ans au moment de l'inclusion. Le délai moyen entre le diagnostic sérologique et l'inclusion augmente régulièrement d'année en année, passant de 40 jours en 1985 à 9 mois en 1988. En 1985, 16% des cas ont été diagnostiqués par les médecins libéraux; cette proportion est de 44% en 1988. Les comportements à risque les plus fréquemment retrouvés chez les hommes sont l'utilisation de drogues parentérales (42%) et l'homo/bisexualité (42%). Chez les femmes, la toxicomanie IV est le comportement à risque le plus fréquent (54%). Depuis 1985, la proportion d'homo/bisexuels masculins a diminué de 45% à 32%; dans le même temps, les transfusés -incluant les hémophiles- sont passés de 6% à 11%, et celle des partenaires hétérosexuels d'un sujet à risque ou séropositif de 4% à 11% (deux sexes confondus). Aucun cas de contamination professionnelle n'a été enregistré. La répartition par groupe de l'infection au moment de l'inclusion est: groupe II: 57%, groupe III: 10%, groupe IV: 33% (N=626). Cette répartition est restée stable depuis 1985.
Conclusion : La prise en charge hospitalière des sujets séropositifs apparait de plus en plus tardive par rapport au diagnostic sérologique. Un tel système de surveillance a permis d'identifier la toxicomanie IV comme le principal comportement à risque à ce stade d'évolution de l'épidémie; il reflète de façon plus exacte que la simple déclaration des cas de SIDA l'evolution de l'infection par le VIH en Aquitaine.

T.A.P.26

INCREASE IN THE REPORTED NUMBER OF HIV-INFECTED PATIENTS IN U.S. DIALYSIS CENTERS FROM 1985 TO 1987.

Martin S. Favero, MJ Alter, Centers for Disease Control, Atlanta, Georgia, 30333, USA.

Objective: To determine trends in the number and types of U.S. dialysis centers that report dialyzing HIV-infected patients and the number of HIV-infected patients.
Methods: From 1985-1987, mail questionnaires were sent annually to all licensed centers in the U.S. to obtain information on the number of patients with HIV infection. Ninety percent of the centers responded in all years.
Results: The percentage of centers that reported providing dialysis for HIV-infected patients increased from 11% (134/1254) in 1985 to 24% (351/1486) in 1987; the number of reported HIV-infected patients increased from 0.3% (244/80,151) to 1.0% (924/97,225). The ratio of clinical asymptomatic HIV infection changed from 1.6:1 in 1986 to 1:1 in 1987. Centers that dialyze HIV-infected patients were located in 34 states, and the geographic distribution of HIV-infected dialysis patients was similar to that reported for all AIDS cases. HIV-infected patients were more likely to be in centers that provided both dialysis and transplant services; were located in hospitals; were government operated; were nonprofit; had larger patient populations (>40); and accepted HBsAg-positive patients for dialysis.
Conclusion: The number of centers that reported dialyzing HIV-infected patients and the number of dialysis patients with HIV infection continue to increase. The characteristics of centers providing dialysis to such patients remain the same.

T.A.P.27

HIV ANTIBODY IN CHRONIC HEMODIALYSIS PATIENTS, UNITED STATES.

Marcus, Ruthanne and the Cooperative Dialysis Study Group. Centers for Disease Control, Atlanta, USA

Objective. To estimate the prevalence and incidence of HIV infection and possible risk of nosocomial transmission of HIV in hemodialysis patients.
Methods. In June 1986, we began a voluntary multicenter study of HIV infection in chronic hemodialysis patients in the U.S.A. Epidemiologic data, risk factor information, and serum for HIV antibody testing were collected from patients on entry into the study and one year later.
Results. As of November 30, 1988, data and serum were collected from 1261 patients in 28 dialysis centers. On entry, 21 patients were reactive for HIV antibody by EIA; 10 of these were positive by Western blot (WB+). Seroprevalence (WB+) was 7/335 (2.09%) for patients tested in 8 centers located in areas from which a high incidence of AIDS has been reported (>500 cases/million population) vs. 3/926 (0.32%) for patients in other areas (p=.005). No center had >2 WB+ patients. The risk factor questionnaire was completed by 1170 patients. All WB+ patients had received transfusions; 5 reported IV drug use. WB+ patients were not more likely to have received a transfusion than WB- patients (10/10 vs. 993/1251; p=.23), but WB+ patients were more likely to report IV-drug use (5/9 vs. 16/1113; OR=85.70, 95% CI=17.75-430.34). Follow-up data have been collected from 542 patients, including 228 in 7 centers with a WB+ patient and 157 in 7 centers located in high AIDS incidence areas; no HIV seroconversions have been documented in dialysis patients.
Conclusions. All seropositive patients had recognized risks for HIV infection. No case of possible nosocomial transmission has been identified. Routine use of infection control precautions is recommended.

T.A.P.28

PREVENTION OF HIV-INFECTION IN PARENTERAL DRUG ABUSERS (PDA'S): ABOUT EVALUATION AND EFFICACY OF OPIATE-SUBSTITUTION-TREATMENT

GRIMM G *, WOLF B *, BORNEMANN R **, BSCHOR F **
* Praxis Dr. med. G. Grimm, Sophienblatt 36, D-2300 Kiel 1; ** Institut für Rechtsmedizin der Freien Universität Berlin, Hittorfstr. 18, D-1000 Berlin 33

Objective: To evaluate the risk of HIV-infection of PDA's under opiate-substitution (here: codein).
Methods: In 1988, four cohorts of PDA's under continous out-patient opiate-substitution-treatment in a private medical praxis were tested for HIV (Elisa, positive results confirmed by WB). Months under observation from seronegative status at 1st consultation to the last HIV-test were counted (for the 1975-84 cohort, time under observation was counted from 1985 onwards only). Similarly to the "Pearl-index" broadly used in obstetrics, a "seroconversion-index" was measured as the seroconversion-rate per 100 years of observation.
Results: From all 323 clients (215 m, 108 f), 32 were HIV-positive at 1st consultation and 54 excluded for other reasons. 237 cases could be evaluated, in which three seroconversions occurred.

	Year of 1st consultation	cases (months under observation) male	female	Seroconversions
Cohort I	1975-84	73 (3219)	32 (1400)	1
II	1985	55 (1946)	30 (1168)	0
III	1986	13 (338)	9 (250)	0
IV	1987	16 (216)	9 (143)	2
	total:	157 (5719)	80 (2961)	3

With a total of 8680 months (or 723 1/3 years) under observation, the HIV-seroconversion-index of these opiate-substituted patients is 0,41 seroconversions per 100 years. Although biases have to be discussed, this seems low compared to the few PDA-HIV-seroconversion-studies available.
Conclusions: 1) The HIV-protective value of opiate-substitution - possibly as result of less or more controlled illicit drug use - can't be neglected; this treatment should be available in the local drug-therapy-spectrum. 2) In the field of HIV-monitoring and evaluation of HIV-preventive measures, also a private praxis - with its limited means, but aided by a research institute - can take part and should therefore be encouraged to do so.

T.A.P.29

HIV AND HEPATITIS B INFECTION ASSOCIATED WITH DIFFERENT RISK BEHAVIORS

Beryl Koblin*, J. McCusker*, B. Lewis**, J. Sullivan***, B. Patashnik****, F. Birch****, *University of Massachusetts, Amherst; **Spectrum House, Inc., Westboro; ***University of Massachusetts Medical Center, Amherst; ****Worcester City Health Department, Worcester, MA, U.S.A.

Objective: To examine the prevalence of hepatitis B markers (HB) and HIV among persons reporting IV drug use (IVDU), sexual contact with an IVDU (SC) or none of these behaviors (N) in community with a relatively low HIV Ab prevalence and with a history of a delta hepatitis outbreak in 1983.
Methods: A community wide surveillance for HIV infection and related behaviors in Worcester, MA occurs at drug treatment centers, prison, public health clinics, and community health centers. A standardized interview is used and blood samples tested for HIV and HB markers.
Results:

Marker	IVDUs(N=215)	SC(N=62)	N(N=176)
HIV(+) Ab	18%	7%	1%
HBsAg±HBcAb	8%	8%	4%
HBsAb±HBcAb	62%	19%	13%
delta Ab	4%	0%	1%

Among IVDUs, a higher percent of HIV(+) had HBsAb ± HBcAb (83%) compared to HIV(-) (57%) (p=.003). 14% of HIV(+) had delta Ab compared to 2% of HIV(-) (p=.01). Data on an additional 300 participants will be presented.
Conclusion: HIV(+) IVDUs were more likely to have had a past hepatitis B or delta hepatitis infection or to have been immunized compared to HIV(-) IVDUs. The prevalence of HBsAg among IVDUs and SC are similar, although IVDUs have 3 times and 2 times higher prevalence of HBsAb and HIV, respectively.

T.A.P.30 REPORT ON AN EXTREMELY LOW RATE OF SEROPOSITIVITY AMONG I.V. DRUG USERS (IVDU) IN A LOCAL HEALTH DISTRICT (LHD) OF NORTH-EAST ITALY.

Mezzelani Paolo(*), Lugoboni F(**), Venturini L(*), Bricolo R(**)
* Istituto di Patologia Speciale Medica - University of Verona - Italy
** Center for Drug Addicts - Local Health District 26 of Veneto Region - Bussolengo (Verona) - Italy

From September 1985 to December 1988 the center for drug addicts of the LHD 26 of Veneto Region (North-East Italy, near Verona) tested IVDU for HIV-1 antibodies. The population of this district is 130.000. Population at risk for addiction (age 15 - 39) is 52.000. In this group the amount of IVDU is estimated ranging from 600 to 800. The IVDU tested (ELISA plus Western Blot if positive) were 345. Only 32 (9%) addicts resulted positive. This is a very low rate in comparison with the nearby districts and the lowest reported in whole country (Italy's mean rate is 50%). Patients were studied with regard to age, sex, length of i.v. addiction, methadone treatment, therapeutic community program, convictions, kind of work, kind of partner relationship. Seropositive and seronegative groups showed no significant difference in any.
There is no evidence for a delayed arrival of the HIV in this district which is in a tourist and well developed area of North-East Italy. Yet the first reported case of LAS in Italy occurred in this district. The following treatment strategies may be accounted for the extremely low rate of seropositivity as suggested by the staff of the Center:

1 - A methadone maintenance program was extensively implemented between 1981-86;
2 - a carefully designed psychosocial program, implying a one-to-one long term therapeutic relationship was performed in these years;
3 - sterile syringes are easily available day and night in the local drugstores;
4 - an intensive campaign against viral hepatitis transmission was incessantly performed by the center.

T.A.P.31 LONG TERM FOLLOW-UP AND ASSESSMENT OF HIV SEROSTATUS AND RISK TAKING IN A COHORT OF 203 INTRAVENOUS DRUG USERS

Carol Skidmore, JR Robertson
Edinburgh Drug Addiction Study, Muirhouse Medical Group, Edinburgh, Scotland

OBJECTIVE: To evaluate current infection and immune status in a group of intravenous drug users previously known to have high seroprevalence (1985 report). Also to evaluate current risk taking and behaviour change.
METHODS: A phased recruitment was carried out between 1983 and 1985 into a cohort study. Between 1987 and 1988 follow-up was carried out and individuals were interviewed and, where appropriate, venesected. Validation included a questionnaire for the primary care physician responsible for the patient at the time of follow-up.
RESULTS: Two hundred and three individuals were contacted, 137 men (67.5%) and 66 women (32.5%). One hundred and sixty four had HIV antibody tests subsequent to 1984 (when the virus is thought to have entered the group). One hundred and five (64%) of those tested were HIV antibody positive, 41.8% had been injecting drugs in the 12 months prior to interview and 28.3% were prolonged abstainers (>2 years). Fifty four percent of the group had children and 40% had a sibling who had used drugs. Sixty six per cent had been in prison; 50% of the group had started injecting between 1980 and 1983; 57% thought they were at risk of HIV from needle sharing but only 23% due to possible sexual transmission. Fifty three percent had not changed sexual practices and only 18% had told sex partners test results. Forty five percent used no contraception (23% of whole group had used a barrier method). Forty six percent had had more than one sex partner since test (range 2->100). Detailed demographic and immunological data are recorded.
CONCLUSION: The natural history of drug injecting had important implications for understanding HIV transmission. Behaviour change was considerable in drug taking and needle sharing but not noticeable in sexual risk factors. The implications for future heterosexual spread are discussed.

T.A.P.32 PREVALENCE OF SYPHILIS(S), HTLV-I(I), HTLV-II(II) & HIV-1 AMONG CRACK(C) AND OTHER DRUG USERS(DUs).

Glaser,Jordan*; Monnier,J.*; D'Angelo,K.*; Drakatos,A.*; Poiesz,B.**; Ehrlich,G.**; et al.
*Richmond Memorial & Staten Island Hospitals, SI. **SUNY at Syracuse,NY,USA.

Purpose: To study prevalence rates of S, I, II and HIV-1 among C & other DUs in view of concern of S-enhanced heterosexual retroviral transmission.
Methods: During 1988, all 957 admissions (624M; 517 white) to RMH detox unit underwent RPR. S was confirmed by MHA-TP. Voluntary retroviral testing was offered. I & II was documented by polymerase chain reaction (PCR). I, II and HIV-1 ELISA were also done. HIV-1 was confirmed by western blot.

Results	S	I PCR+	II PCR+	HIV-1+
C alone	15*/321 (4.7%)	1/37 (2.7%)	2/37 (5.4%)	7/141 (5.0%)
IVDU alone	10#/388 (2.3%)	6/58 (10.3%)	6/58 (10.3%)	79/274 (28.8%)
C & IVDU	1/110 (0.9%)	2/18 (11.1%)	1/18 (5.6%)	28/82 (34.1%)
Other DU	1/138 (0.7%)	0/10 (0.0%)	0/10 (0.0%)	0/54 (0.0%)

*7/8 tested were HIV-1 negative. #6/7 tested were HIV-1 positive.

For HIV-1+ C users: All 35 belonged to high risk groups (28 IVDUs, 3 male homosexuals, 3 long-term sex partners of IVDU, 1 from endemic region) and only 1 had S. Four DUs had both I & II. For both I & II, 2/9 (22%) DUs were PCR+ but ELISA-. Two male C users with prostitute contact had either I or II. One black female C user with no known risk factor had II. No C user with I or II had S.
Conclusions: C and IVDUs had a high rate of S. S in C users was not associated with HIV-1. The high rate of HIV-1 among C users was related to concurrent risk factors and not widespread heterosexual transmission.

T.A.P.33 NEEDLE SHARING PRACTICES AMONG INTRAVENOUS DRUG USERS IN A STATE ALLOWING THE PURCHASE OF INJECTION EQUIPMENT

Lawrence, DW*, Atkinson, W*; Risi, G**; Lauro, A**
*Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, USA, **Louisiana State University School of Medicine Orleans, LA, USA

Objective. To determine the frequency of needle sharing practices among intravenous (IV) drug users in Louisiana, a state which does not control needles by prescription.
Methods. During March-August 1988, 380 self-identified IV drug users seeking treatment in a large public hospital in New Orleans were interviewed regarding needle sharing practices, frequency of drug use and drug(s) of choice. Hospital records were reviewed to obtain demographic information and HIV serologic status.
Results. Eighty-one percent of subjects were male and 73% were black. Mean age of subjects was 32.5 yrs (range 16-69 yrs). The most frequent drug injected was cocaine (31%). Drugs were injected ≥ once per day by 76%. Overall 66% of subjects admitted that they regularly used needles which had been used by others. No significant differences in needle sharing were found by sex, race, frequency of injection or drug of choice. Two of forty (5%) subjects tested were HIV seropositive.
Conclusion. Needles are not controlled by prescription in Louisiana. More than 65% of subjects admitted to sharing needles, similar to the rate found in areas in which needles are controlled. This suggests that legal availability of injection equipment does not significantly reduce sharing behavior in this population.

T.A.P.34 THE AIDS PROBLEM AND DRUG-REHABILITATION IN THERAPEUTIC COMMUNITIES (TC)

Olgiati Marco
Department of Social Psychiatry University Hospital, Zürich, Switzerland.

Objective: Determine rate of infection and the effects of AIDS on the members of TC's and their human relations.
Methods: The study covers 523 heroin-addicts who were treated in 40 TC's in Switzerland in 1986. N=433 patients were tested.
Results: Rate of infection of the tested persons: 55% HIV-positive and 11.3 % of the positive patients already suffered from typical symptoms related to the infection. Of particular interest was to study the communication and discussion about AIDS preventing measures and their implementation in TC. The findings were, that large and hierarchically structured TC's were more conscious of AIDS and its effects than small and family-like structured TC's.
Discussion: Prevention efforts should be established as a regular issue within the therapeutic programs of TC's. But as well, there would be opportunities of talking in private atmosphere with a therapist and other residents in a trustful relationship.

T.A.P.35 COORDINATED COMMUNITY PROGRAM FOR HIV SURVEILLANCE AMONG IVDUS

Lewis, Benjamin*, Sullivan, J.**, Birch, F.**, Noone, S.**, McCusker, J.***, Koblin, B.***, et al.
*Spectrum House, Inc., Westboro, MA 01581, ** Worcester Health Department, Worcester, MA, ***University of Massachusetts, Amherst, MA, U.S.A.

Objective: To conduct a community-wide surveillance for HIV/high-risk behaviors among an estimated 3000 IVDUs and sexual contacts in the second largest city in New England (175,000).
Methods: The Worcester (MA) AIDS Consortium, a network of drug treatment, public health and criminal justice organizations enrolls, interviews, counsels and tests IVDUs at multiple sites. Active and passive follow-up is implemented for HIV+ and admissions to drug treatment and public health programs. This project is implemented in the context of a city-wide AIDS risks reduction program including HIV education, counseling, testing and support, distribution of bleach/condoms and priority admission to drug treatment for HIV⊕.
Results: Of 1200 tested, 48% were needle users (77% male, 13% female). 18% of needle users tested ⊕. Of Hispanic IVDUs 35% tested ⊕, Blacks 30%, Whites 80%; of IVDUs in jail 21%, in drug treatment 14%. Use of bleach has increased from 5% to 64%. Over 100 persons testing ⊖ entered drug treatment. Results on 3000 participants will be presented.
Conclusions: HIV prevalence among IVDUs has increased by 2% over the past year to 18% with the greatest increase in the jail (5%). Higher seropositivity among minority groups may in part be explained by differences in drug-use behavior. The surveillance has been instrumental in targeting resources to the minority community. This model has applicability to moderately-sized cities where HIV prevalence is still low.

T.A.P.36 NO TREND IN YEARLY HIV-SEROPREVALENCE RATES AMONG IVDU IN AMSTERDAM: 1986-1988.

Van Haastrecht, Harry JA;Van den Hoek JAR;Coutinho RA.
Municipal Health Service, Amsterdam, The Netherlands.

Objective. To describe and explain HIV-seroprevalence rates over time.
Methods. From december 1985 till december 1988, 560 IVDU entered a long term follow-up study. Yearly HIV-seroprevalences among these IVDU at entry into the study, were analysed.
Results. In 3 consecutive years (1986-1988) HIV-seroprevalence rates were 33.3%, 28.3% and 27.8% respectively, showing no significant trend over time (p=0.22). Since a selection-bias might be covering up an actual increase here, in that cases with the highest risk for HIV-infection participated earlier in the study than others, an attempt was made to control for this possible bias. Previously determined independent riskfactors for HIV-infection were multivariately controlled for, resulting in odds-ratio estimates for HIV-infection in the consecutive years (relative to 1986) that hardly differed from the uncontrolled ones: 1987 OR=0.79 vs OR=0.84; 1988 OR=0.75 vs OR=0.87 for uncontrolled and controlled respectively. However, conventional confidence-intervals encompass even quite large increases in the rate of HIV-infection from 1986 onwards, so caution is needed in interpreting these results.
Conclusion. HIV-seroprevalence rates among IVDU in Amsterdam appear to be relatively stable since 1986. This result needs confirmation by larger scale seroprevalence studies to be conclusive.

T.A.P.37 EPIDEMIOLOGY OF AIDS ASSOCIATED WITH INTRAVENOUS DRUG USE, UNITED STATES, 1979-1988.

Richard Selik * **; Petersen, L.*, Buehler, J.*
* Centers for Disease Control (CDC), Atlanta, GA, USA
** Macfarlane Burnet Centre for Medical Research, Victoria, Australia.

Objective: To describe characteristics of, and trends in, AIDS cases in intravenous drug users (IVDUs) in the United States (US).
Methods: We reviewed AIDS cases reported to CDC through 1988.
Results: There were 21,914 cases of AIDS in IVDUs (57% heterosexual men, 27% homosexual men, 16% women), 1,657 in sex partners of IVDUs, and 761 in children born to mothers who are IVDUs or sex partners of IVDUs. From 1984 to 1988, heterosexual IVDUs increased from 17% to 23% of adult AIDS cases (in part due to the 1987 revision of the case definition), while homosexual IVDUs declined from 9% to 6% of adult cases. For heterosexual IVDU cases, relative risk for cumulative incidence among blacks and Hispanics compared to whites was 19 and 23 for males and 19 and 14 for females, respectively. In the northeast, cumulative incidence for IVDU AIDS cases was as high as 1/200 among blacks and Hispanics in some urban areas, and cases in IVDUs and other IVDU-associated cases exceeded all other AIDS cases by the end of 1988. Age at diagnosis of AIDS has been increasing for minority heterosexual IVDUs (black males 5.8 and Hispanic males 4.3 months per year since 1983) but not for other IVDUs.
Conclusion: Heterosexual IVDUs represent an increasing proportion of the AIDS epidemic in the U.S. The burden of AIDS associated with drug use falls most heavily on blacks and Hispanics, particularly in the northeast.

T.A.P.38 SECOND NATIONAL SURVEY ON HIV INFECTION, AT RISK BEHAVIOURS AND BEHAVIOURAL CHANGE AMONG ITALIAN DRUG USERS.

Salmaso, Stefania, Sasse H., Conti S.
Istituto Superiore di Sanità, Rome, Italy.

Objective: To estimate, among drug users attending public assistance centres in Italy, the prevalence of HIV-1 infection and of at risk drug use behaviours and sexual lifestyle; to evaluate tendency to change behaviours at risk and determinants of the change.
Methods: In each centre attending subjects during October 1988 have been interviewed according to a standard questionnaire, collecting information on personal characteristics, on syringes/needle sharing on kind of sexual relationships. Moreover change of any at risk behaviours and reason for changing were investigated. Presence of serum antibodies against HIV-1 was assayed for all enrolled subjects.
Results: Fifty four centres (out of a total of 467 in the country) completed the survey. A total of 1350 subjects from 16 regions were included. Detailed elaboration is in progress. According to results of the first national survey, expected seroprevalence is around 40% of tested subjects, with increased risk associated to sharing of syringes/needles either for preparing or for injecting the drug.
Conclusion: Although prevalence studies among subjects attending public health assistance centres can be affected by biases such as self-selection of drug users, onset confounding bias, reliability of answers, a series of surveys conducted with the same methodology is a useful tool for monitoring trends in the spread of infection and in behaviours at risk, more than for estimating absolute prevalence of such changing factors.

T.A.P.39 INTRODUCTION OF HIV INFECTION AMONG INTRAVENOUS DRUG ABUSERS (IVDAs) IN LOW PREVALENCE CITIES

Battjes, Robert; Pickens, R.
National Institute on Drug Abuse, Rockville, MD, USA

Objective. To examine possible modes of introduction of HIV into IVDA populations in areas with low HIV infection rates.
Methods. IVDAs admitted to methadone treatment in 1987-88 in Trenton, NJ, Chicago, IL, San Antonio, TX, and Los Angeles, CA were tested for HIV antibodies by ELISA, confirmed by Western blot (n=1,154). Demographics, drug use, and sexual history were obtained by standardized interview. Seropositives (n=54) and demographically matched seronegative controls were compared on relevant AIDS risk factors.
Results. Seropositives and seronegative controls did not differ in frequency of IV use, needle sharing or needle cleaning, or number of drugs injected. There were also no differences between the two groups in rates of males reporting sex with other males, blood transfusions since 1982, injecting drugs or having sex in high HIV prevalence areas, and acquaintance with persons with AIDS. Seropositives were, however, more likely to report sharing a needle with a homosexual or bisexual male (25.0%) than were seronegatives (3.8%) (p<.002) (OR 8.5; 2.2-33.0). Differences between seropositives and seronegatives reporting injecting in shooting galleries (52.8% vs. 35.2%) approached statistical significance (p<.07).
Conclusion. Comparisons of seropositives and seronegative controls suggest that transmission of HIV infection by needle sharing between homosexual/bisexual IVDAs and heterosexual IVDAs may be an important means by which HIV is introduced among heterosexual IVDAs in low prevalence areas.

T.A.P.40 HETEROSEXUAL TRANSMISSION OF HIV AMONG INTRAVENOUS DRUG ABUSERS (IVDAs)

Battjes, Robert*; Amsel, Z.*; Pickens, R.*; Sholinsky, P.**; Ritz, L.**; Brown, L.***
*National Institute on Drug Abuse, Rockville, MD, USA; **SRA Technologies, Alexandria, VA, USA; ***Addiction Research Treatment Corp., New York, NY, USA

Objective. To examine the extent to which HIV is transmitted among heterosexual IVDAs through sexual contact.
Methods. IVDAs admitted to methadone treatment in New York City during 1987-88 were tested for HIV antibodies by ELISA, confirmed by Western blot. Demographic, drug use, and sexual history were obtained by standardized interview. Heterosexual IVDAs who reported having sex with IVDA sex partners (IVSPs) (n=214) were compared with those who reported having no IVSPs (n=175) using bivariate and logistic regression analyses.
Results. Initial bivariate analyses indicated that IVDAs with any IVSPs were more likely to be HIV+ than those with no IVSPs (p<.02), while the number of IVSPs was not related to infection. Analyses by gender indicated that the relationship between IVSP and HIV+ held for males (p<.01), but not females. There was no statistically significant relationship between having an IVSP and seropositivity, for either the total sample or males, when selected demographic and drug use variables were controlled.
Conclusion. The increased HIV risk associated with having IVSPs appears to be due to differences in drug use practices, not sexual transmission. The study supports needle sharing as the primary mode of HIV transmission among IVDAs. The possible contribution of sexual transmission should not be ruled out. Possible effects may be too subtle to be detected in these analyses.

T.A.P.41 INCIDENCE AND RISK FACTORS OF HIV INFECTION IN A COHORT OF ITALIAN DRUG ADDICTS (NISDA STUDY).

Alfredo Nicolosi, Northern Italian Seronegative Drug Addicts Study, National Research Council and University of Milan, Milan, Italy.

Objective. To study the incidence of HIV infection in a population at risk, to identify risk factors, to describe natural history of infection and transmission dynamics.
Methods. Intravenous Drug Abusers (IVDA) are recruited from methadone clinics, hospital departments of infections diseases and various outpatient services. IVDA who agree to participate to the study are first administered a questionnaire about lifestyle habits, medical and laboratory examinations, and a psychiatric interview. They are subsequently followed up.
Results. 653 IVDA have been recruited from January 1987 to December 1988 and followed for different periods of time. 20 seroconversions have been observed. The prevalence is very high of makers of HBV infections (68%), of Herpes Simplex (83%), of CMV (86%), of EBV (45%) in the entire population. The mean number of T4 lymphocytes was 1199, with 30% of subjects presenting less than 900 cells. Previous infections, type of drug used and patterns of drug assumption, sexual behavior and immunologic variables have been related to seroconversion in order to verify their role in the risk of HIV infection.
Conclusions. The number of seroconversions is not sufficient yet in order to draw firm statistical infruences about risk factors, although a low number of T4 cells at first visit was significantly lower in individuals who later seroconverted. Recruitment and follow-up are continuing, thus allowing a more detailed study of risk factors as well as of behavior and preventive attitudes of IVDA.

T.A.P.42

HIV SEROSTATUS AND RISK BEHAVIORS OF STREET IVDUS

Corby, Nancy H.*, Rhodes, F.** and Wolitski, R. J.**
*Department of Public Health, Long Beach, CA, USA.
**AIDS Research & Education Project, California State University, Long Beach, CA, USA.

Objective. To determine pre-intervention seroprevalence, drug usage, daily activities, sexual behaviors, and AIDS attitudes among street IVDUs in Long Beach, CA.

Methods. Personal interviews were conducted with 325 street IVDUs (66% male, 34% female) between June and September 1988; 44% were White, 35% Black, 16% Hispanic, and 5% Asian/Other. HIV-antibody serostatus was obtained on 193 persons.

Results. Drugs commonly injected were heroin (75%), cocaine (34%), speedballs (28%), and amphetamines (13%). Needles were shared by 88%. 70% of IVDUs said they cleaned their works at least three-fourths of the time. Of those cleaning, 73% reported using bleach or alcohol and 27% using water alone. 42% reported having non-IVDU sex partners, and 18% said the partner did not know of their drug use. 38% of IVDUs were prostitutes or had traded sex for drugs. 70% of IVDUs rated good health as highly important. 61% had been in a drug-treatment program at some time (40% within the prior 9 months). Ten (5.2%) of the 193 persons tested for HIV-antibody were seropositive (9 males, 1 female). There was no difference between the proportion of homosexual/bisexual vs. heterosexual males with respect to serostatus ($p = .178$). HIV serostatus, sexual orientation, or whether one was a prostitute bore no significant relationship to reported degree of concern about AIDS or change in sexual behavior because of AIDS ($p > .10$).

Conclusion. The large number of IVDUs who indicated health was of high personal importance, who cleaned needles with bleach/alcohol, and who reported recent drug treatment suggests this population will be receptive to targeted AIDS-prevention efforts.

T.A.P.43

A COMPARISON OF HIV-1 INFECTION RATES IN MINNESOTA (MN) IV DRUG USERS BETWEEN 1987 AND 1988

Thomas, J*; Danila, R*; Osterholm, M*; Shultz, J*; Falkowski, C**; MacDonald, Kristine*; et al. *MN Department of Health, **MN Department of Human Services, Minneapolis, MN U.S.A.

Objective. To determine HIV-1 seroprevalence and risk factors associated with HIV-1 infection for IV drug users (IVDUs) in a low prevalence area.
Method. Cross-sectional surveys of IVDUs were conducted at chemical dependency treatment clinics in MN in 1987 and 1988. All clients were asked to participate; approximately 80% were enrolled each year.
Results. In 1987, 231 IVDUs participated and in 1988 335 participated. Demographic characteristics in the 2 groups were not significantly different. Prevalence of HIV-1 infection was: 3/231 (1.3%) in 1987 and 5/335 (1.5%) in 1988. For the 1988 survey, characteristics associated with seropositivity were male-to-male sex ($p<0.005$), history of residence in NYC since 1977 ($p<0.001$), and sex with an HIV-infected partner ($p<0.001$). Rates of needlesharing were similar in the 2 groups (93.3% in 1987 and 90.9% in 1988). However, for both years, those who shared were likely to share < 50% of the time and to share with only one person. Use of bleach to clean needles increased from 8.3% of respondents in 1987 to 33.0% in 1988 ($p<0.001$). 132 of the participants in 1987 also participated in 1988; 3 (2.3%) seroconverted in the intervening year.
Conclusion. This study demonstrates low HIV-1 prevalence, probably due to late introduction of HIV and tendency to share needles with only one person at a time. However, the 1-year incidence rate of 2.3% indicates a gradually increasing problem.

T.A.P.44

IS CONDOM USE AN INDEPENDENT RISK FOR HIV IN IV DRUG USERS?

Celentano, David; Vlahov, D.; Anthony, J.C.; and Bernal, M.
The Johns Hopkins University, Baltimore, Maryland U.S.A.

Objective. To determine the relationship between reported recent condom use and HIV risk behaviors among IV drug users (IVDUs).
Methods. IVDUs being screened in Baltimore for a study of the natural history of HIV infection in IVDUs (the ALIVE Study) were interviewed about their history and recent use of condoms as well as behaviors that increase or reduce risks for HIV infection associated with IV drug use. We report on the results from the initial 1,5175 (1,301 males) persons screened.
Results. Among male IVDUs, 60% report never using condoms, as compared to 55% of females. Among men, frequency of drug injection and the number of persons with whom needles are shared were modestly associated with frequency of condom use, although there was no relationship with needle cleaning practices. Among women, frequency of drug use, borrowing needles and disinfection practices were independent of condom use, although needle sharing was associated with less frequent condom use. For both men and women, there was no relationship between recent condom use and HIV serostatus (with 25% overall being HIV positive). Further, awareness of serostatus prior to this screen was independent of recent condom use for both sexes. Importantly, knowledge and attitudes about the effectiveness of condoms in preventing HIV transmission were high, yet they were unrelated to reported condom usage.
Conclusion. Significant barriers to condom use exist in the IVDU community. These results demonstrate that the adoption of condom use to reduce the risk of HIV transmission is independent of other HIV risk behaviors among IVDUs. Unlike gay men, awareness of serostatus does not promote condom behavior.

T.A.P.45

RISK FACTORS FOR HIV-1 INFECTION AMONG INTRAVENOUS DRUG USERS (IVDUS) (1978-1987).

Vlahov, David, Muñoz, A, Celentano DD, Cohn S, Shapiro M, Anthony JC. The ALIVE Study, The Johns Hopkins School of Hygiene and Public Health, Baltimore, Maryland, USA.

Objective To reconstruct risk factors over a nine year period for current HIV-1 infection among a sample of currently active IVDUs.
Methods IVDUs recruited from the community for an HIV natural history study (ALIVE), at baseline underwent venipuncture and interview. Data on drug use patterns from 1979-87 were summarized in 9 variables: number of shared injections (SI), number of non-shared injections (NSI) and use of shooting galleries (SG) during 3 periods (1979-81, 82-84, 85-87). Analyses were performed using logistic regression methods.
Results Among 1736 IVDUs, 24.7% had WB confirmed anti-HIV-1. Three variables (SI:79-81, the change in SI from 79-81 to 82-84, and SG:85-87) were significant in the multivariate model. Relative Odds (RO) for 2 SI/day vs. no SI in 79-81 was 1.44 (95% C.I.=1.02, 2.04). RO for increasing to 2 SI/day in 82-84 from no SI in 79-81 vs. no SI in both periods was 1.99 (95% C.I. = 1.30, 3.07). RO for any SG in 85-87 was 1.58 (95% C.I. = 1.24, 2.02). For IVDUs initiating in 85-87 (n=258), no variables were significant, but SI was positively associated with seropositivity.
Conclusions In this sample, behavior throughout all nine years is associated with current infection. Nonsignificant NSI and small ROs for SI suggest sharing and not frequency of injections is associated with infection. These data indicate that different practices over time have contributed to current HIV-1 infection.

T.A.P.46

ASSOCIATION BETWEEN FORMER PLACE OF RESIDENCE AND SEROSTATUS OF IVDUs IN SOUTH FLORIDA

Comerford, Mary*; Chitwood, D.D.*; McCoy, C.B.* et Trapido, E.J.*. *University of Miami School of Medicine, Miami, FL. USA

Objective. To examine mobility patterns of a sample of IVDUs in South Florida and to determine if place of past residence is associated with HIV seroprevalence.
Method. IVDUs (722) in drug treatment in South Florida were tested for antibodies to HIV and administered a questionnaire which included a history of place of residence since 1/1/78.
Results. Seroprevalence varied by ethnicity: 7.6% non-Hispanic white, 36.4% non-Hispanic black and 26.8% Hispanic. Of 722 subjects enrolled in the study, 478 (66.3%) had lived in an area(s) other than Miami at some time between 1/1/78 and baseline testing. Past residence in New York City (NYC) was associated with seroprevalence for non-Hispanic whites. Of 60 non-Hispanic whites who had previously resided in NYC, 14 (23.3%) were HIV AB+ while 24 (5.5%) of 439 non-Hispanic white IVDUs who had not lived in NYC were HIV AB+. This association was not seen among non-Hispanic blacks or Hispanics who had a higher seroprevalence than non-Hispanic whites. There was no association found between seroprevalence for HIV and prior residence in areas other than NYC.
Discussion. IVDUs are a mobile population and can carry the virus from one geographic area to another. Migration between high prevalence areas and low prevalence areas may be responsible for an increase of rates in the low prevalence areas.

T.A.P.47

HIV INFECTION IN FEMALE INTRAVENOUS DRUG USERS IN SAN FRANCISCO

Wolfe, Hannah *; Keffelew, A.*; Bacchetti, P.*; Meakin, R.*; Brodie, B.*; Moss, A.R.*.
*University of California San Francisco/SF General Hospital, California, USA.

Objective. We examined risk factors for HIV seropositivity in female intravenous drug users in treatment in San Francisco.
Methods. IVDUs in methadone and detoxification treatment in SF are offered anonymous HIV testing with notification of results. Here we report on 220 female IVDUs studied in 1988.
Results. Median age of female IVDUs was 36. 55% were white, 23% black, 22% hispanic/other. Median number of children was 1.7. 54% had been in jail in past 5 years; 27% had been paid for sex in past year. Median times in treatment was 5.
26/220 female IVDUs were HIV Ab+ (12%) (White 6%; Black 28%; hispanic 11%).
Seropositivity was associated with needle sharing with >10 people in past year ($p=.02$), shooting gallery use in past year ($p<.001$), and splitting drug by drawing it into syringe ($p<.001$).
Seropositivity was also associated with sexual risk factors including history of syphilis ($p=.04$) and PID ($p=.04$) and number of sex partners in previous year (none verus any; $p<.01$), but not with paid sex. 0/23 women with no partners in previous year were Ab+ versus 19/159 (12%) of those with 1-5 partners and 7/32 (22%) of those with >5 partners.
117 women reported bleach use to sterilise needles. 9/52 (17%) reporting <1 yr of use were positive versus 5/47 (11%) with 1-2 years use and 0/18 (0%) with > 2 years use.
Conclusion. HIV seropositivity in female IVDUs was associated with sexual-transmission risk factors as well as with drug-use risk factors. No women reporting no sexual partners in previous year and none reporting more than 2 years bleach use were seropositive.

T.A.P.48

DRUG ABUSE PATTERNS AND ETHNICITY IN IVDA DURING THE EARLY YEARS OF THE HIV EPIDEMIC

Novick, David, M.*; Trigg, H.L.*; Des Jarlais, D.C.**; Friedman, S.R.***; Vlahov, D.****; Kreek, M.J.*****; et. al.
*Beth Israel Medical Center, New York, N.Y., U.S.A.,** N.Y. State Division of Substance Abuse Service, New York, N.Y., U.S.A.,*** Narcotic and Drug Research Inc., New York, N.Y., U.S.A.;**** Johns Hopkins Univer., Baltimore, MD, U.S.A.;***** The Rockefeller University, New York, N.Y., U.S.A.

Objective. To determine factors associated with HIV infection in intravenous drug abusers (IVDA) during the early years of the HIV epidemic in New York.
Methods. Records from studies of chronic liver disease (CLD) in IVDA during 1978-83 were reviewed. In these studies, limited clinical and demographic data had been linked to code numbers of sera which had subsequently been tested for HIV antibody by ELISA (Abbott) and Western blot. Available data included age, sex, race, sexual preference, heroin only vs. heroin and cocaine, and duration and age of onset of IVDA and of alcohol abuse.
Results. Only 2 (11%) of 18 white patients with CLD were HIV-infected, compared with 34 (39%) of 88 black or hispanic patients ($p=0.03$). Among injectors of cocaine with heroin, 30 (52%) of 58 had anti-HIV compared with 6 (13%) of 48 injectors of heroin only ($p<0.0001$). No other factors listed above were linked to anti-HIV. In a multiple logistic regression, anti-HIV was associated with injection of cocaine with heroin ($p<0.0001$), black patients ($p=0.02$), and hispanic patients ($p=0.049$).
Conclusion. IV cocaine users as well as black and hispanic IVDA were disproportionately HIV-infected during the early years of the epidemic. Cocaine with heroin and ethnicity were independently linked to anti-HIV.

T.A.P.50

INTRAVENOUS DRUG USE AS A RISK FACTOR FOR AIDS AND HIV INFECTION IN LOUISIANA, 1981-1988

Atkinson, William*,**; Troxler, S.*; Dal Corso, M.*,**; McFarland, L.*
*Louisiana Department of Health and Hospitals, New Orleans, LA, USA;
**Tulane University School of Public Health, New Orleans, LA, USA.

Objective. To determine trends in intravenous drug use (IVDU) as a risk factor for AIDS and HIV infection in Louisiana (LA).
Methods. AIDS cases are identified by an active hospital-based surveillance system. Case data is collected by hospital record review, and physician and patient interview. Seroprevalence data is from blinded testing of new entrants at two drug treatment centers in New Orleans.
Results. As of 12/30/88, 1062 adult and 14 pediatric cases of AIDS were identified. IVDU was associated with 172 (16%) of all cases in adults (65IVDU, 100-homo/bisexual and IVDU, 7-heterosexual contact with IVDU). Four (29%) of pediatric cases were from IVDU in a parent. IVDU was the primary risk factor for AIDS in 14% of blacks vs. 3% of whites. The proportion of AIDS cases with IVDU as the primary risk factor increased from 3% in 1985 to 9% in 1988. Of 175 new entrants to IVDU treatment centers in New Orleans in 1988, 6.3% were found to be HIV seropositive.
Conclusion. IVDU accounts directly or indirectly for 16% of AIDS cases in LA. The proportion of AIDS attributable to IVDU has increased significantly in the past three years. Blacks account for a disproportionate number of cases among IVDUs. The prevalence of HIV in IVDUs in New Orleans in 1988 is relatively low (6.3%).

T.A.P.52

COMPARISON OF PREVALENCE OF HIV INFECTION IN IV DRUG USERS (IVDU) FROM FOUR DIFFERENT TESTING AND TREATMENT PROGRAMS.

Cohn, David; Douglas, J; Kolsis, J; Feeney, F; Judson F.
Denver Disease Control Service (DCS), Denver, CO, USA

Objective: To compare the prevalence of HIV infection in IVDU accessed through 4 different testing and/or treatment programs in Denver in 1988.
Methods: In 1988, HIV counseling and testing was offered by DCS to IVDU through 4 programs: 1) Counseling and Testing Site (CTS), 2) Sexually Transmitted Diseases (STD) Clinic, 3) Substance Treatment Services (STS-a methadone maintenance program), and 4) Project Safe (PS- an indigenous street outreach program for IVDU not in treatment).
Results:

	No. HIV positive / No. tested (%)							
	CTS		STD		STS		PS	
Gay/bisexual men	20/51	(36)	17/50	(34)	0/1	(0)	2/5	(40)
Female prostitutes	2/40	(5)	3/89	(4)	1/6	(16)	1/22	(5)
Heterosexual men	14/305	(5)	3/227	(1)	1/73	(1)	3/100	(3)
Heterosexual women	2/168	(1)	1/123	(1)	0/34	(0)	0/37	(0)
TOTAL	38/564	(7)	24/489	(5)	2/114	(2)	6/164	(4)

Conclusion: The prevalence of HIV infection in IVDU who are not gay or bisexual men is low in Denver, and rates are comparable in programs with different selection criteria. Determining prevalence rates among different programs is useful both to monitor secular trends and to better estimate the community burden of HIV infection in IVDU.

T.A.P.49

DEMOGRAPHIC AND BEHAVIORAL FEATURES OF HIV INFECTION IN INTRAVENOUS DRUG USERS (IVDUs) IN NEW YORK CITY DRUG TREATMENT PROGRAMS: 1985-1988

Brown, Lawrence S.*; Phillips, R.*; Ajuluchukwu, D.*; Battjes, R.**; Primm, B.J.* and Nemoto, T*. *Addiction Research and Treatment Corporation, Brooklyn, NY, USA. **National Institute on Drug Abuse, Rockville, Md, USA.

Objective. To examine the trends in demographic and HIV-related behavioral factors of IVDUs enrolled in methadone treatment.
Methods. Following informed consent, standardized questionnaires of drug use, sexual behaviors, and medical history were administered to IVDUs recently admitted to drug treatment. Sera was analysed for HIV-1 using ELISA and western blot techniques.
Results.

Year	Number Tested	Number (%) HIV Seropositive
1985	469	255 (54)
1986	262	159 (61)
1987	218	131 (60)
1988	223	115 (52)

The tendency in ´85, ´86 and ´88 toward higher infection rates for non-whites, as compared to whites, did not hold for ´87. Differences in HIV infection rates between these cohorts were most appreciated in black and male IVDUs. Between 1987-8, there were important differences between drug and sexual behaviors.
Conclusion. While these findings suggest modification of behaviors among IVDUs, the HIV infection rate may be equally explained by saturation.

T.A.P.51

TRANSMISSION OF HIV BY MOBILITY IN INJECTION DRUG USERS (IDU)

*RP Brettle, *G Jones, *J Davidson, *C Bisset, ¯SM Burns, JM Inglis, *Infectious Diseases Unit; ¯Regional Virus Laboratory, City Hospital, EDINBURGH. Scotland.

OBJECTIVE: To establish those areas in which Edinburgh based IDU had shared injection equipment.
METHOD: All IDU attending the Edinburgh Counselling Clinic were asked about injection practices including sharing equipment in non-Edinburgh locations.
RESULTS: By the end of 1987, 1143 patients had attended the clinic of whom 396 (34.6%) were IDUs, 17 had never injected in Edinburgh. The mean age of the remaining 379 was 26 years (16-46) with a M/F ratio of 1.72:1. In 351 HIV status was determined and 110 (48.8%) of the 225 males and 73 (55.3%) of 139 females were positive. 101 (26.6%) IDU, 73 males and 28 females, admitted to sharing equipment in 140 non-Edinburgh sites. Three had shared in Southern Europe and retrospective tests of stored sera showed that one seroconverted for HIV shortly after returning to Edinburgh. This individual went on to share with numerous other users with later seroconversion dates.
CONCLUSION: The IDU related HIV epidemic in Southern Europe began in 1981 and the unexpected mobility of drug users explains the pockets of IDU related HIV infection as well as other blood borne viruses in Northern Europe. This mobility must be taken into account when considering preventative strategies for HIV.

T.A.P.53

HUMAN IMMUNODEFICIENCY (HIV) AND HUMAN T-LYMPHOTROPIC (HTLV-I/II) VIRUS INFECTIONS ASSOCIATED WITH INTRAVENOUS DRUG ABUSE (IVDA).

Stevens, Roy, Wethers, J., Samsonoff, C., and Berns, D. New York State Health Department, Albany, U.S.A.

Objective. To describe the prevalence of HIV and HTLV-I/II infections among people in N.Y. State with IVDA as a risk factor for the transmission of blood born infection.
Methods. Specimens submitted for HIV test from anonymous subjects with a history of IVDA (3463 sera) or with no acknowledged risk for infection (1965) were tested for HIV and HTLV-I/II antibody by EIA and western blot. EIA reactive sera with HIV blot bands at 24 and 41 and/or 120/160 Kd or HTLV-I/II bands at 24 and 46 and/or 61/68 Kd were recorded as positive. Results were merged with age, sex, geographic origin and race/ethnicity data and analyzed on a main-frame computer.
Results. In IVDA subjects the prevalence of antibody to HTLV-I/II or HIV and HTLV-I/II was 5.6 and 4.1% respectively. In people with no acknowledged risk it was 0.86 and 0.75. For both populations studied, HIV prevalence was highest at age 30-39; HTLV-I/II or both HIV plus HTLV-I/II was higher at age 50 or greater. Proportion of IVDA sera positive for HIV also positive for HTLV-I/II was 142/1845 or 7.6%; of sera positive for HTLV-I/II also positive for HIV, it was 142/196 (72.4%).
Conclusions. About 1 in every 13 IVDA subjects infected with HIV in N.Y. State is also infected with HTLV-I/II. Conversely, about 72% of HTLV-I/II infected IVDA subjects are infected with HIV.

T.A.P.54 HIV INFECTION AMONG INTRAVENOUS DRUG USERS (IVDU's) IN NYC

Truman, Benedict*; Lehman, J.S.*; Brown, L.**; Peyser, N.***; Peters, D.*; DesJarlais, D.****et al.
*New York State Department of Health, Albany, New York, USA, **Addiction Research Treatment Corp., NY, NY, USA, ***Beth Israel Medical Center, NY, NY, USA, ****New York State Division of Substance Abuse Services, NY, NY, USA.

Objective. To compare current HIV seroprevalence and risk factors among "new entrants" and "old clients" of Methadone Maintenance Treatment Programs (MMTP's) in New York City (NYC).

Methods. Since June 1988, sera from IVDU's at 28 MMTP clinics were tested blindly for HIV by ELISA and WB. Non-identifying demographic and treatment data were collected at entry or on annual physicals. Logistic regression models identified risk factors for infection in "new entrants" and "old clients".

Results. As of Jan. 1989, 33.4% of 1062 clients were HIV+. Data were complete for 403 "new entrants" (45.9% HIV+) and 305 "old clients" (27.2% HIV+). "New entrants" have higher infection rates than "old clients" in all subgroups.

	RACE			BOROUGHS OF RESIDENCE					Ever
	Bl.	Hisp.	Wh.	Bronx	Brook.	Manh.	Queens	St. Isl.	Treated?
New	52.8	41.2	39.4	31.0	46.0	49.7	43.8	33.3	51.4
Old	32.1	37.9	17.0	28.6	19.4	35.2	14.6	12.5	NA

HIV infection was associated with a history of previous treatment for drug abuse among "new entrants" [OR(95% CI)=1.6(1.1,2.5)], and with Black race [2.2 (1.1,4.5)] hispanic ethnicity [2.5(1.2,4.9)] and Manhattan residence [2.8(1.2, 6.9)] among "old clients".

Conclusion. In NYC MMTP's, "new entrants" are 1.7 times as likely as "old clients" to be HIV+. Prevalence was lower than previously reported by both groups.

T.A.P.55 HIV SEROPREVALENCE IN INJECTING DRUG USERS IN SOUTH LONDON 1985-88

S Sutherland,* TJ McManus†
*PHLS Dulwich Hospital, †King's College Hospital London SE5, England

Objective. To estimate the HIV seroprevalence in injecting drug users as monitored by an HIV testing laboratory in South London.

Method. The frequency of HIV antibody positivity in injecting drug users attending clinics and General Practitioners in the South London area was estimated. 555 men and 286 women were tested. 619 of those tested were over 25 years of age.

Results.

Prevalence of HIV antibody in IDU's

	1985		1986		1987		1988		1985-88	
	No	(%)	No	(%)	No	(%)	No	(%)	No	(%)
Male	0	13(0)	11	203(5)	8	198(4)	9	141(7)	28	555(5)
Female	1	6(11)	7	90(8)	4	115(3.5)	2	75(3)	14	286(5)
Total	1	19(5)	18	293(6)	12	313(4)	11	216(5)	42	841(5)

Those results compare with a seropositivity of 19% among homosexual men and <1% in heterosexual men and women tested in the same centre over the same period. Most of those found to be HIV Ab positive (57%) were patients attending the sexually transmitted disease clinic requesting HIV antibody testing.

Conclusion. The HIV antibody seroprevalence in this group rose very suddenly but appears to have levelled off. The majority of those tested were over 25 years of age and gave evidence of having changed their needle sharing habits. More younger addicts need to be tested and outreach methods are being used to reach them.

T.A.P.56 HIV SEROCONVERSION IN A GROUP OF IVDAs (1985-1988)

Giorgio Barbarini, S. Edo, T. Gola, S. Guerini, S. Lopez, P. Sanbartolomeo
Clinic of Infectious Diseases IRCCS S. Matteo University of Pavia - ITALY

Objective. To demonstrate the incidence of seroconversion for HIV in a cohort of IVDAS.

Methods. Since first months of 1985 a group of 491 drug addicts, followed by Drug Abuse Surveillance Organisms of Abbiategrasso (USSL 73), Crema (USSL 53) Magenta (USSL 72), Vigevano (USSL 78) and Voghera (USSL 79) in southern Lombardy, has been tested every six months for HIV antibodies.

Results. At June 1985 we found 253 seropositive IVDAs (202 males and 51 females); at December 1988 28 of the previously negative drug addicts (16 males and 12 females) were found positive.

In the cohort of earliest HIV positive subjects 21 developed AIDS until now.

Conclusion. These data suggest that intravenous drug abuse put IVDAs at increased risk for HIV infection as long as drug behaviour continues, even followed by appropriate centers, and this is not a good result of preventive measures.

So the possibility of sexual spread from IVDAs (many drug addicts, either women, either men, sell themselves for buying drug) to common people requires great attention.

T.A.P.57 HIV PREVALENCE AMONG DIFFERENT GROUPS OF INTRAVENOUS DRUG USERS IN SEATTLE, WASHINGTON.

McGough, James P.*; Wood, R.*; Harris, N.*; Kleyn, J.**; Carlisle, M.***.
*AIDS Prevention Project, Seattle, Washington USA; **University of Washington, Seattle, Washington, USA ***King County Detoxification Facility, Seattle, Washington, USA.

Objective: To estimate HIV antibody seroprevalence among different groups of intravenous drug users (IVDU's) in Seattle and King County.

Methods: IVDU's were tested at the AIDS Prevention Project (APP), a testing site promoted for persons at high risk of HIV infection, at the King County Jail, from the streets of Seattle, and at the County's drug and alcohol detoxification facility.

Results:	APP Tested (%+)	Jail Tested (%+)	Street Tested (%+)	Detox Tested (%+)	TOTAL Tested (%+)
Gay/bi men	356 (30.3%)	31 (6.5%)	11 (27.3%)	10 (30.0%)	408 (28.2%)
Other men	265 (4.2%)	82 (2.4%)	15 (0%)	101 (5.0%)	463 (3.9%)
Women	234 (2.6%)	48 (4.2%)	7 (0%)	56 (1.8%)	345 (2.6%)
TOTAL	855 (14.6%)	161 (3.7%)	33 (9.1%)	167 (5.4%)	1216 (11.8%)

Conclusion: Preliminary data indicate that HIV seroprevalence among IVDU's varies greatly by site. The prevalence is greatest among male IVDU's who report having had sex with other men.

T.A.P.58 SEXUALLY TRANSMITTED DISEASES (STD's) AND HIV SEROPREVALANCE IN A COHORT OF IV DRUG USERS

Nelson, Kenrad E., Vlahov D., Solomon L., Chowdhury, N.
The ALIVE Study, Johns Hopkins University, Baltimore, MD, U.S.A.

Objective. To correlate the history of a sexually transmitted disease and HIV seroprevalence in a cohort of active IV drug users (IVDU's).

Methods. A cohort of IVDU's, without AIDS, was recruited for a study of the natural history of HIV infection by community outreach. Histories of STD's at baseline were correlated with HIV seroprevalence.

Results. Overall 441 (24.7%) of 1785 participants were HIV seropositive at baseline. STD histories by HIV serostatus were as follows:

	HIV +	HIV -	P-Value (Chi-square/Fishers)
Syphilis	17.5%	12.2%	0.005
Gonorrhea	56.7%	52.9%	0.15
Genital HSV	3.6%	2.2%	0.09
Genital Warts	7.7%	6.4%	0.34
Other STD's	18.8%	19.6%	0.77

Among male homosexual/bisexual IVDU's a syphilis history was strongly associated with HIV seropositivity (20/44; 45%) compared with HIV negatives (18/114, 15.7%; p = 0.001). Among heterosexuals, (53/372, 14.2%) of HIV seropositives and (141/1184, 11.9%) of HIV seronegatives had a history of syphilis (p = N.S.).

Conclusion. Our study suggests that sexual transmission may account for some HIV infections among active IV drug users, especially in those who are male homosexuals/bisexuals. Prospective studies are required to more clearly define the risks of sexual transmission of HIV in IVDU's.

T.A.P.59 SERO-EPIDEMIOLOGY OF HIV-1 INFECTION AMONG INJECTION DRUG USERS SEEKING MEDICAL HELP IN MONTREAL: 1985-1988.

Bruneau, Julie*, Lamothe, F.*, Soto, J.*, Brabant, M.*, Vincelette, J.* and Fauvel, M.**. *CRC André-Viallet, Hôpital Saint-Luc, Université de Montréal, and **Laboratoire de santé publique du Québec, Montréal, Canada.

Objective: To determine the prevalence and trends of HIV-1 infection among IDUs hospitalised for detoxification and correlate seropositivity with risk factors.

Methods: Every IDU hospitalised between March 1985 and Sept. 1988 had a serum taken, tested for Hepatitis B markers and saved frozen at - 20°C in a serum bank. Sera were retested for HIV-1 antibodies using ELISA and RIPA & IFA confirmation tests. Patient records and serologic results were matched and analysed anonymously using an unlinked method.

Results: From a total of 294 patients, 13 were HIV-1 seropositives (4.4%). There were no association between HIV-1 infection and sex, age, ethnic origin, sexual orientation, prostitution, drug of choice or needle sharing. Of 234 patients with known sexual orientation, 226 were heterosexual. Only one of the seropositive was bisexual. Twelve of the thirteen seropositive were hepatitis B markers positive in contrast to 111 of the 281 negative (p < 0.001). The annual prevalence of HIV-1 infection at the Detox Unit was: 1985, 7.1%; 1986, 3.0%; 1987, 2.0%; 1988, 6.6%; overall, 4.5% (confidence limits: 2.2 - 6.7%).

Conclusion: HIV-1 infection prevalence in Montreal IDUs seeking detoxification remained stable between 1985 and 1988 and is associated with the presence of hepatitis B markers. The opportunity for preventive strategies is great.

Surveillance du SIDA et marqueurs de l'infection
Surveillance of AIDS and Marker Infections

T.A.P.60 COMPARATIVE MONITORING OF HIV-SPREAD IN THE IVDU POPULATION OF BERLIN AND HAMBURG

Bschor, Friedrich*; Bornemann, R.*; Pueschel, K.**; Rex, R.***; Platz, W.****; Lueth, R.***** et al.
*Freie Universität Berlin, **Universität Hamburg FRG, ***Justizvollzug Berlin (West), ****Karl-Bonhoeffer-Nervenklinik Berlin(West), *****Justizvollzug Hamburg ,Federal Republic of West Germany

Objective: Local monitoring of HIV-spread in IVDU population
Methods: Since 1985 nearly all cases of drug related deaths in Berlin(West) were HIV-AB tested; N=362; Test ratio (=TR) 97%. Since 1988 we try to broaden the HIV-indicator-mosaic by including data of defined groups of living IVDU's on a voluntary basis: entrants in detoxification, admissions in prison.
Results: In the autopsy cases the following seropositivity rates were

Found:	1985	1986	1987	1988
Berlin	30%	49%	49%	38%
Hamburg	0%	23%	16%	13%

Because of selfselection the data-gathering in the groups of living IVDU's was full of gaps, especially in Berlin. In Hamburg the positivity rate in detox-cases 1988 was 13% (TR 73%), in prison cases 12% (TR 93%), results very close to the autopsy rates. In Berlin the difference was great: detox cases 1988 24% (TR 50%), prison cases 19% (TR not known).
Conclusion: Seropositive rates in drug related deaths seem to represent quite a realistic picture of the HIV-situation. In Cities of similar structure the HIV-spread in the IVDU population may show great differences.

T.A.P.61 UNDERREPORTING OF AIDS CASES, SOUTH CAROLINA, 1986-1987.

Conway, George A.*, and **, Niemeyer BL**, Rion P**, Pursley C**, Cruz C**, Heath CW, Jr.**, et al. *Centers for Disease Control, Atlanta, Georgia, USA, **South Carolina Department of Health and Environmental Control, Columbia, South Carolina, USA

Objective: To assess the completeness and accuracy of AIDS case reporting in South Carolina.
Methods: Approximately 600,000 hospital discharge billing records from January 1986 through June 1987 were searched by computer for AIDS-defining conditions. The resulting 1,513 clinical records were manually reviewed.
Results: Of these, records for 351 discharges for 163 individuals were classified as being definitely AIDS-related by the 8/87 revised CDC AIDS case definition. 153 of these individuals met the older (pre 8/87) case definition, and should have been reported to the State AIDS case registry. After controlling for reporting lags, 92 of these were indeed reported. Thus, 39.9% of all AIDS cases from the State for the study interval were not reported. Reported versus non-reported groups were not significantly different by age, race, sex, risk behavior, primary clinical diagnosis, or employment status. Individuals receiving AZT were significantly more likely to have been reported (p< .001). Percentage reporting by hospital ranged from 18/20 (90%) down to 0/4 (0%). There was also a considerable range in reporting compliance among physicians.
Conclusion: There was considerable underreporting of AIDS cases in South Carolina for the study interval. Similar studies should be repeated in other states, and may have important implications for the interpretation of surveillance data and for planning in the epidemic.

T.A.P.62 USING DEATH CERTIFICATES (1985-1987) TO ESTIMATE THE COMPLETENESS OF AIDS CASE REPORTING IN ONTARIO

B. Lily Montano*; R. J. Johnson**; E.M. Wallace***
*Epidemiologist, Public Health Branch, Ontario Ministry of Health;**Resident in Community Medicine, University of Toronto; *** AIDS Coordinator, Public Health Branch, Ontario Ministry of Health,Toronto, Ontario, Canada

Abstract. The completeness of AIDS case reporting in Ontario was assessed by reviewing all AIDS death certificates compiled by the Registrar General between January 1, 1985 and December 31, 1987. Several demographic variables were used to match death certificates with cases reported to the provincial AIDS registry and the Chandra Sekar and Deming method was used to estimate the completeness of case reporting. The estimated completeness of case reporting was 80.9% in 1985 (95% C.I.=75.9% to 85.9%), 71.6% in 1986 (95% C.I.=67.6% to 75.6%), 75.3% in 1987 (95% C.I.=72.4% to 78.2%), and 75.1% overall for 1985-1987 (C.I.=72.2% to 78.0%). The completeness of reporting in 1985 was significantly higher than in 1986 (chi-square, p<0.01) but was not significantly different from that calculated for 1987 (chi-square, p>0.05). Cases who were never married were 1.5 times more likely to be reported in 1985 than in 1986, and there was a significant increase in the promotion of such unreported cases from 1985 to 1986 (chi-square, p<0.02) Reporting was not associated with the patient's age, sex, occupation or place of residence. The deficiency in AIDS case reporting could adversely affect the long-term planning of health care resources and the development of programmes to prevent and control the spread of AIDS.

Key Works: AIDS, Case reporting, Death Certificates, Registry

T.A.P.63 RISK GROUP DIFFERENCES IN REPORTING DEATHS IN AIDS PATIENTS

Devine, Owen; Berkelman, RL; Karon,JM.
AIDS Program, Centers for Disease Control, Atlanta, Georgia, USA

Objective. To determine any variation among risk groups in the percentage of AIDS cases diagnosed at death and in the delay in reporting deaths.
Methods. Deaths of known AIDS patients are reported to CDC by state and local health departments. All deaths in adult AIDS patients diagnosed between 1984 and 1988 were examined. Patients with death in the same month as diagnosis were classified as diagnosed at death. The number of months between death and report was calculated for all deaths reported in 1988 (date of death report was first recorded in October, 1987). Risk group was defined by the mode of HIV transmission.
Results. For cases diagnosed in each of the years 1984 and 1987, 10%-11% of AIDS cases in homosexual/bisexual males who were not intravenous drug users (IVDU) were diagnosed "at death," compared to 16%-18% in heterosexual IVDUs diagnosed in the same years. Roughly one fifth of all transfusion related AIDS diagnoses were made "at death" between 1984 and 1987. Deaths among heterosexual IVDUs were 50% more likely to be reported after a delay of 12 or more months than deaths in non-IVDU heterosexuals. Eleven percent of the known deaths occurring among homosexual/bisexual non-IVDUs in 1986 were not reported until 1988 compared to 19% of the heterosexual IVDUs who died the same year.
Conclusion. Both the proportion of cases diagnosed at death and the delay in reporting deaths may vary among risk groups. Survival estimates must consider these possible sources of bias. It may be desirable to estimate survival only among AIDS patients with reported survival of at least one time period (month or calendar quarter).

T.A.P.64 HIGH PERCENTAGE OF NON-REPORTED CASES OF AIDS IN HEMOPHILIACS OF THE FEDERAL REPUBLIC OF GERMANY

Frösner, Gert G.
Max von Pettenkofer-Institut, University of Munich, FRG.

Objective. Estimation of non-reported AIDS-cases in the FRG.
Results. Questionaires sent to all hemophiliac treatment centers in the FRG revealed in October 1987 the presence of 183 hemophiliacs with AIDS (ellipse 156-158, 1987). Only 82 clotting factor associated cases of AIDS were officially registered at that time (44.8 %). In a similar evaluation done end of October 1988, the number of cases was 351, but only 133 (37.9 %) were registered. Between first and second evaluation the number of hemophiliacs with AIDS increased by 168, the number of registered cases by 51 (30.4 % of new cases registered). The data suggest an increase in percentage of non-reported cases. In addition, reported cases in hemophiliacs show a misleading trend: doubling time decreased to 18 months, but is still 13 months in reality. Assuming the same percentage of non-reported cases for all risk groups, not 2580 reported but 6807 cases of AIDS might have occurred in the FRG till November 1988. The doubling time of case might still be 12 months instead of 15 months, as deduced from reported figures.
Conclusion. Probably more than half of all diagnosed cases of AIDS are not reported and the percentage of non-reported cases seems to increase. The completely voluntary reporting system of the FRG will not give sufficiently reliable data.

T.A.P.65 ACTIVE SURVEILLANCE FOR PEDIATRIC HIV INFECTION IN LOS ANGELES COUNTY

Mascola, Laurene *; Evans M.*; Frederick T.*; Church, J.**; Bryson, Y***; Kovacs, A.**; et al
*Los Angeles County, Dept. of Health Services, Los Angeles (L.A.), Calif.; **University of Southern California, L.A., Calif.; ***University of California, L.A., Calif., USA

Objectives. To describe the development and implementation of an active surveillance system for pediatric HIV infection in Los Angeles County (LAC), California, and to present data collected from January 1982 through December 1988.
Methods. As of March 1988, pediatric and adult cases satisfying the CDC's surveillance criteria for AIDS were reported through a combination of active and passive surveillance measures. In March 1988, an active surveillance system for all aspects of pediatric HIV infection (HIVI) was initiated. Cases were classified using the classification system for HIV in children <13 years (April 87). Twelve hospitals that routinely report pediatric HIVIs are contacted on a bimonthly basis and a supplemental information form is filled out on each case.
Results. As of December 31, 1988, 139 (HIVIs) (P0-P2) had been reported; 50 (36%) of which had AIDS. This represents a 79% increase in reported pediatric AIDS since March 1988. From 3/88 to 12/88, adult AIDS cases increased overall by 29% and 40% among women. Sixty-three percent of all pediatric HIVIs were male; 24% are dead. Almost one-third (n=38) of HIVI cases were symptomatic (P-2) yet not classifiable as pediatric AIDS. Thirty-six percent had a parent at risk and 55% were among minorities. In contrast, among the 13 most recently reported HIVI cases since September 1988, 77% had a parent at risk, and 77% were among minorities. Of the pediatric AIDS cases, over 90% had opportunistic infections, 14% had Lip and only 4% had Kaposi's sarcoma.
Conclusion. An active surveillance system for pediatric HIV infection and the use of the new classification system substantially increased pediatric AIDS case reporting in LAC. Although LAC has small numbers of pediatric HIV infections, recent increases in cases in minority groups with parents at risk are evident, which permit the targeting of health education efforts.

T.A.P.66

MEDICAL SCHOOL SUBCONTRACT ENSURES STATE-WIDE ACTIVE AIDS SURVEILLANCE IN NEW JERSEY

Schneider, D. Jean, and Lavenhar, M.
UMDNJ - New Jersey Medical School, Newark, New Jersey, U.S.A.

Objective. To expand New Jersey Health Department capacity to obtain accurate AIDS surveillance data.
Methods. Unique subcontract with state medical school effected to produce increase in active AIDS surveillance activities on a state-wide basis.
Results. Two years of experience with subcontract resulted in:

1. State-wide active surveillance sites increased as responsibility for 12 sites (affiliated hospitals) was shifted to medical school.
2. Concentration on active rather than passive surveillance within New Jersey made possible.
3. Partnership provided data on approximately 40% of New Jersey AIDS cases.
4. Accessibility to hospital AIDS data improved by use of medical school personnel.
5. Teaching hospitals provided with accurate AIDS census data.
6. Retroactive surveillance activities made possible.
7. More complete and accurate AIDS data made available for CDC, state and hospital planning, resource allocation and development of intervention programs.

Conclusion. This unique partnership between a state health department and a state medical school has proven a successful method for expanding active AIDS surveillance efforts and has enabled New Jersey to lead the nation with the first total active AIDS surveillance system.

T.A.P.68

USE OF AUTOMATED SECONDARY DATA SETS FOR AIDS SURVEILLANCE

Hamidi, Cyrus*; Hidalgo, J.*
*Maryland Department of Health and Mental Hygiene, Baltimore, Maryland, USA.

Objective: To describe an evaluation method for AIDS surveillance using alternate data sources to identify unreported AIDS cases.
Methods: Maryland hospital discharge records from January 1, 1985 to December 31, 1987 were selected from automated discharge summaries from Maryland hospitals, using a developed set of ICD-9-CM codes including: pneumocystis carinii pneumonia (136.3); malignant neoplasm of skin (Kaposi's Sarcoma) (173.0-173.9); immune deficiencies (279.2-279.9); AIDS (042.); and others. The selected records were matched to the Maryland AIDS case registry by birthdate, sex, race, ZIP code, and service dates. Records which did not match were sorted by hospital and then reviewed by surveillance staff of the AIDS Administration and the Baltimore City Health Department. These medical records were identified by birthdate and hospital medical record number.
Results: of 2,256 discharge records falling within the ICD-9-CM code set, 1,425 (63%) were identified as previously reported Maryland AIDS cases. A total of 831 admissions from 54 hospitals were then investigated. By December 1988, 623 (75%) had been resolved. Of these 623 records, 55 (8.8%) were previously reported AIDS cases, 162 (26.0%) were AIDS cases who were not Maryland residents, 255 (40.9%) were cases with non-HIV related conditions, 109 (7.2%) were seropositive for HIV with no AIDS-indicative opportunistic infections, 20 (3.2%) records were not locatable, and 22 (3.5%) cases were found which were not previously reported.
Conclusions: According to this method of evaluating the surveillance system, 879 (97.6%) of 901 Maryland AIDS cases diagnosed between January 1, 1985 and December 31, 1987 were reported. It was found that the earlier coding methods were being used after the establishment of the ICD-9-CM 042. code for AIDS in October 1986. In addition, it was shown that a much higher number of Maryland non-residents were using Maryland hospitals than anticipated. Finally, based upon this pilot study, this evaluation technique can be used on a periodic basis to routinely evaluate the surveillance system.

T.A.P.70

EVALUATING COMPLETENESS OF NEW YORK CITY'S CASE REGISTRY.

Hindin, Rita H; Thomas P; Nicholas A; Miller N; Schultz S; and the others in the New York City Dept of Health AIDS Surveillance Unit, New York City, NY , USA.

Objective. To categorize, as CDC AIDS cases or non-cases, persons with NYC death certificates (DCerts) giving AIDS, Pneumocystis carinii pneumonia (PCP), or Kaposi sarcoma (KS) as cause of death but not reported through routine surveillance.
Method. All New York City DCerts 7/86-6/87 with AIDS, PCP, or KS as underlying cause of death were identified. The hospital records of those not already in the AIDS Surveillance Registry are being reviewed.
Results. Three thousand and one such records were identified of which 882 were not in the Registry. Follow-up is completed for 616: For 130 there is no hospital record and 4 were excluded. Among the other 482, 168 were missed by routine surveillance (I); 67 were reportable cases only according to the 9/87 expansion of the CDC case definition (CDC def) (II); 98 did not fulfill the CDC def only because of no serology (III); 146 had other HIV-related illness not fulfilling CDC def (IV). HIV risk factors for these 482 by group (I-IV) and for cumulative NYC cases (17,754 as of 12/88) (V):

Risk Category	I	II	III	IV	V
Man Sex w/Men (MSWM)	43%	21%	29%	13%	51%
IVDU (IV Drug Use)	36%	46%	50%	62%	34%
MSWM & IVDU	5%	6%	8%	6%	4%
Other	15%	27%	13%	18%	10%

Conclusion. Risk factor distribution differs significantly by type of HIV-related illness. DCerts are useful for evaluating routine surveillance.

T.A.P.67

EVALUATING RACIAL CLASSIFICATION AMONG NATIVE AMERICAN INDIANS WITH AIDS IN LOS ANGELES COUNTY, CALIFORNIA

Lieb, Loren*; Kerndt,P.*; Hedderman,M.**; Chase,E.***; Yao,J.****; Conway,G.*****
*Los Angeles Co. Dept. of Health Services, and **AIDS Project Los Angeles, Los Angeles, Calif, ***American Indian Free Clinic, Long Beach, Calif, ****IHS, Calif, *****CDC, Atlanta, Georgia, USA

Objective. To evaluate race classification, method of race assessment and case ascertainment of Native American Indians (NAI) with AIDS in Los Angeles County (LAC).
Methods. Nine community-based AIDS service organizations (CBASO) in LAC were surveyed to determine the number of NAI AIDS cases in their client population and methods of race assessment. Death certificates for all male NAIs age 15-54, from 1980 to 1987, were reviewed to identify causes possibly related to AIDS. The names of suspect deceased NAI AIDS cases were compared to the LAC AIDS surveillance registry. Personal identifiers were not available for active CBASO clients.
Results. The CBASOs responded that of their clients with AIDS, 63 were NAI (30 active and 33 deceased or inactive), compared to 6 AIDS cases (2 living and 4 deceased) among NAIs reported to the LAC AIDS surveillance registry as of January 18, 1989. Twenty-five of 30 active NAI clients were re-interviewed regarding their race; 8 (32%) clients were confirmed to be NAI and 17 were reclassified to other races. The 17 racially misclassified clients had selected *Native American* from a list of race categories included on the CBASO intake form. The names of deceased CBASO NAI clients were matched to the LAC AIDS surveillance registry; 27 of 33 (82%) were reported, of which only 1 was recorded as NAI. Of 108 deaths reported among NAI males age 15-54 between 1980 and 1987, 3 were AIDS-related and had been reported to the LAC AIDS surveillance registry; 1 was reported as NAI.
Conclusion. Race was reclassified for 68% of CBASO clients initially recorded as NAI. If the proportion of racially misclassified deceased clients is the same as that of re-interviewed active clients, then NAIs may be under-represented by as much as 50% in LAC AIDS surveillance statistics.

T.A.P.69

A RECORD LINKAGE STUDY TO DETERMINE THE DEGREE OF UNDER-REPORTING OF AIDS CASES IN CANADA.

Calzavara, Liviana*; Craib, K.**; Coates, R.*; Schechter, M.**; Johnson, J.*; Elmslie, K.***. *University of Toronto, Toronto, Ontario, Canada, **University of British Columbia, Vancouver, B.C., Canada, ***Federal Centre For AIDS, Ottawa, Ontario, Canada.

Objectives: To estimate the rate of under-reporting of AIDS to the Bureau of Epidemiology & Surveillance, Federal Centre For AIDS (FCA), Canada.
Methods: In January and October 1988, initials, birthdates and place of residence of 66 cases of AIDS known to the Toronto Sexual Contact Study (TSCS) and 64 cases known to the Vancouver Lymphadenopathy-AIDS Study (VLAS) were sent to the FCA along with comparable information on 1041 other study participants who were not known to have AIDS. A manual record linkage was conducted by the FCA linking this data to the national registry of reported cases.
Results: The rate of under-reporting ranges from 10.9% (7/64) (VLAS) to 18.2% (12/66) (TSCS). The TSCS data show that under-reporting has increased from 0% in 1984 to 40% in 1987, whereas rates have been stable in the VLAS. In the TSCS, AIDS diagnoses are established and reported by physicians not involved in the research in contrast to the VLAS where physicians involved in the research are also responsible for reporting cases.
Conclusions: If the under-reporting rates observed in this study are reasonable estimates of the national rate then 253 to 423 cases of AIDS have not been reported as of January 1, 1989. Differences in responsibilities for case reporting between centres may explain differences in observed rates of under-reporting.

T.A.P.71

LINKAGE OF RECORDS OF PERSONS IN THE NEW YORK CITY (NYC) AIDS CASE REGISTRY WITH DEATH CERTIFICATES FILED IN NYC.

Hindin, Rita H. *; Singh, TP.**; Thomas, P.*;
Blum S.**; Rautenberg E.*; and the others in the *New York City (NYC) Dept. of Health (DOH) AIDS Surveillance Unit, NYC, USA,**NYC DOH Office of Epidemiology and Statistical Services, NYC, USA.

Objective. To analyze a data set which links AIDS Registry (AR) records of New York City (NYC) cases with their NYC death certificates (DCerts).
Methods. A computerized search of all NYC DCerts 1980-87 linked cases in AR to DCerts. The linking process was iterative and utilized sequentially less stringent criteria for the identification of possible matches.
Results. Among the 11,132 files with name known in AR, 7,052 (63%) were linked to DCerts. Among the 7,052, 17% had not had vital status updated prior to linking the files. Dcert underlying causes of death for the 7,052:

ICD-9 Code/Illness	Number (%) of 7052 cases
279.1,042-044 136.3, 173/ AIDS, HIV-related, PCP,KS	6274 (89.0)
485-486/Broncho/Pneumonia, organism unspecified	128 (1.8)
117.5/ Cryptococcosis	45 (.6)
010-018/ Tuberculosis	28 (.4)
Other HIV-associated conditions (cf. MMWR 36 No.S-7)	87 (1.2)
304.9/Unspecified drug dependence	102 (1.4)
Other ICD-9 Codes	388 (5.5)

Codes 485-6 and 304.9 are more common causes of death among AIDS cases whose risk factor is intravenous drug use than among cases with other risk factors.
Conclusion. Linkage of AR files with DCerts is a useful tool for increasing the information available for individual cases and for updating vital status.

T.A.P.72

TRENDS IN THE OUTPATIENT DIAGNOSIS OF AIDS: IMPLICATIONS FOR EPIDEMIOLOGIC ANALYSIS AND SURVEILLANCE

Hopkins, Sharon*, Lafferty, W**; Honey, J*; Burlich, M*.
*Seattle-King County Department of Public Health;**Washington State Department of Social and Health Services, Seattle, Washington, USA.

Objective. We sought to monitor trends in the site (inpatient vs. outpatient) of AIDS diagnosis. This information is used in targeting active AIDS surveillance programs and interpreting epidemiologic data.
Methods. The site of initial AIDS diagnosis was determined as part of routine AIDS surveillance and entered into the ARS computerized database.
Results. An increasing proportion of AIDS cases in King County are diagnosed outside of hospitals. Prior to 1986, 6% of cases were diagnosed as outpatients (OPDx), rising by year to 25% of cases diagnosed in 1988.
Conclusions. Most local AIDS surveillance programs depend heavily on hospital-based reporting and validation studies of reporting completeness generally use hospital-based methods such as discharge databases. Our data indicate that the proportion of AIDS cases with an outpatient diagnosis is rapidly increasing, making hospital based surveillance systems less effective. Outpatient diagnosis may also influence the analysis of epidemiologic parameters. For example, of Washington State AIDS cases diagnosed prior to 1988, cases with outpatient diagnoses survived significantly longer than other cases (41.1 months vs. 14.8 months). Confirmation of these trends in other jurisdictions is needed. Provider and clinic-based surveillance and validation techniques should be developed in light of these findings.

Year	# AIDS Cases	No.OPDx	(%)
1982-85	155	9	(6%)
1986	183	19	(10%)
1987	244	52	(21%)
1988	219	55	(25%)

T.A.P.73

HOSPITAL-BASED AIDS REPORTING IN A HIGH INCIDENCE AREA, HOUSTON, TEXAS, USA

Cole, N.; Falletti, Robert L. and Phelps, A.F.
Bureau of Epidemiology, Houston Dept. of Health & Human Services, Houston, Texas, USA

Objective: To provide a mechanism to facilitate and evaluate the timeliness and completeness of AIDS reporting in selected hospital areas of an indigent care hospital.
Methods: The selected hospital areas were evaluated through observing and interviewing staff to assess current reporting practices. Recommendations were made based on the assessment. Recommendations included implementing a new reporting system utilizing a re-designed report form and protocol. These changes were carried out in a pilot study for two months. The pilot consisted of three stages, education, implementation, and evaluation of the program.
Results:

	Before Pilot May-June 1988	During Pilot Nov-Dec 1988
Number of cases	10 cases	20 cases
Mean lag time (Dx to Report)	6 months	3.9 months
Completeness	0%	37%

Conclusion: It has been generally excepted that in areas of high AIDS incidence hospitals are experiencing limitations in time and staff to report AIDS cases. With the implementation of this pilot, there has been and increase in case reporting at this facility. Through assessment, education and tailored procedures, hospitals in high incidence areas can continue to meet their legal obligation to report AIDS cases to the local health authority.

T.A.P.74

EVALUATION OF AIDS CASE REPORTING IN MASSACHUSETTS

Oddleifson, Stephanie*; Heinze-Lacey, B.*; Makarewicz, L.**; Day, J.**; Seage, G.*; *Boston and **Massachusetts AIDS Surveillance Programs (BMASP), Boston, MA. USA

OBJECTIVE. To assess completeness and timeliness of MA AIDS case reporting.
METHODS. To validate completeness of reporting, BMASP audited infection control logs and case lists at 20 reporting sites with >25 cumulative cases. Unreported cases were recorded. Death certificates (DC), tumor registry (TR) and Mycobacteria (M) reports were also reviewed for unreported cases. The timeliness (reporting delay)of cases reported in 1987 and 88 was calculated as months between diagnosis and report.
RESULTS. Completeness. Ninety-three unreported cases were found in the audit, representing 7% of all cases diagnosed at audited hospitals. No differences were found in underreporting rates by risk, sex, race, or case definition. Rates differed by site; 3 hospitals had 68% of unreported cases. Underreporting was mainly due to a lack of individuals assigned the duty to report at those sites. DC, M, and TR reviews found 59 cases, 3% of all cases diagnosed. Underreporting in MA is estimated at 8%.

Timeliness. Of reported cases, 76% are received within 2 months of diagnosis; 90% within 6 months. No differences in reporting delay were found by risk, sex, race, or case definition; however, differences by site were significant.
CONCLUSION. Regular audits of hospital infection control logs as well as reviews of M, DC, and TR reports are needed to maximize reporting completeness. MA AIDS case reporting is 92% complete, with 90% of reported cases received within 6 months after diagnosis.

T.A.P.75

DMAC : A software for cooperative epidemiology of HIV infection

Rossi O., Lesieur S., Longinovic D., Valleron, A-J
Centre Coopérateur de Données sur l' Epidémiologie de l'Immunodéficience Humaine,
INSERM SC4, Paris, France

Objective : The French Ministry of Health has set up a national system of information on HIV infection based on 23 major hospitals (Centres d'Information et de Soins sur l'Immunodéficience Humaine: CISIH) scattered all over the country. Concerning epidemiology, the aim of the system is to provide a global view of the infection at its different stages and to be a core for further collaborative clinical/epidemiological studies.

Method : A software (DMAC : Dossier Minimum Anonyme Commun) has been devised to facilitate the cooperative epidemiology between all collaborating centers. It runs on IBM PC compatibles, with Ms Dos.

Results : The functions of the software include : derivation of an anonymous code corresponding to each patient (see Thirion, Sambuc, San Marco, Rev Epid et Santé Pub,1988,36,36-42) which protects confidentiality but allows to automatically retrieve the patients who consult in different places and correct accordingly the national database ; data entry and edition of the information at each visit of follow up; automatic computation of the stages of the patients according to CDC or ICD 9 ; automatic production of the notification of AIDS to the General Direction of Health when/if the patient satisfies the criteria of AIDS ; coding of the file using the technique of the Vernam cypher in order to fully guarantee the security when data are exchanged between the clinical centers and the Coordinating Data Center ; statistical facilities to allow each participating center to analyse locally its own data. The computerized informations include only those biological measurements and clinical data which, by consensus, have been found to be routinely recorded on seropositive patients. Modifications of the software can easily be performed for those clinical centers who want to devise collaborative studies for which additional informations have to be collected.

The system has received the agreement of the Commission Nationale de l'Informatique et des Libertés. The written and informed consent of the patient must be obtained.

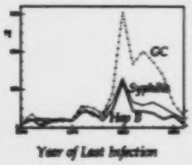
The software may be obtained upon request to the coordinating data center.

T.A.P.76

TEMPORAL TRENDS FOR PAST SEXUALLY TRANSMITTED DISEASES IN MEN WITH AIDS AND ARC IN SAN FRANCISCO

Feigal, David W.*; Hollander, H**; Ziegler, J***; Clement, M*; Volberding, PA*;
Medical Services of * San Francisco General Hospital; ** University of California, SF; *** Ft. Miley VA Hospital; UCSF, San Francisco, CA, U.S.A.

Objective: To describe the temporal trends of the last prior sexually transmitted diseases (STDs) in patients who developed AIDS and ARC which correlate with cessation of sexual practices which may also transmit HIV.
Methods: The UCSF AIDS Registry has collected detailed medical histories since 1985 from a cohort of 2605 individuals, who are asked the dates of their last episode of syphilis, gonorrhea (GC), and hepatitis B as well as dates of HIV associated conditions and onset of AIDS.
Results: Dates of last GC (n=1497), syphilis (n=775), and Hepatitis B (n=324) each peaked in 1980 and by 1982 were approximately 50% of the 1980 rates. The hepatitis B rate fell most rapidly, even though affecting the smallest proportion of the cohort possibly reflecting saturation of infection in a subgroup with the riskiest behaviors. The mean time from hepatitis B to AIDS onset was 8.0 years (n=240) and from syphilis 7.8 years (n=344) which corresponds to estimates of the mean incubation time of HIV to AIDS. Of 645 men with GC who developed AIDS 45 (7%) had GC within 1 year, 55 (8%) 2 years before, 82 (13%) 3 years before AIDS onset. The decreasing rate of infection may reflect safe sex education and /or the development of prodromal symptoms.
Conclusions: The time of last prior STD peaked and began declining even before there was an awareness of AIDS. However, as indicated by GC which was newly acquired within one year of onset of AIDS by 1 in 14 patients, there is a need for continued interventions to stop transmission through safer sexual practices.



T.A.P.77

IMPACT OF THE REVISION OF THE CDC AIDS CASE DEFINITION ON CASE REPORTING

Hamidi, Cyrus*; Hidalgo, J.*; Rogers, A.*
*Maryland Department of Health and Mental Hygiene, Baltimore, Maryland, USA.

Objective: To describe the impact of the September 1987 revision of the CDC AIDS case definition on case reporting through December 31, 1988.
Methods: Following the AIDS case definition revision in 1987, the Division of AIDS Surveillance categorized all reported cases on whether they met the older case criteria or the newer, broader definition. Retrospective case investigation was accomplished by an evaluation project using hospital discharge records and by reinvestigation of previously-reported cases which had not met the older definition.
Results: The percentage of cases meeting each case definition by December 31, 1988 is as follows:

Definition	Year of Diagnosis					
	Before 1985	1985	1986	1987	1988	Total
Old	125 (99%)	169 (89%)	236 (86%)	336 (75%)	339 (73%)	1205 (80%)
Revised	1 (1%)	21 (11%)	38 (14%)	110 (25%)	123 (27%)	293 (20%)
TOTAL	126	190	274	446	462	1498

The 293 revised definition cases do not include 41 cases that were reported as revised definition cases but developed conditions which reclassified them under the old definition. Of these 293, 137 (46.7%) had died by the end of 1988 without having been reported as progressing to old definition AIDS. This resulted in a 10.9% increase in reported cases (1498 total cases/137 permanent revised definition cases) due to the revised AIDS case definition, in the 16 month period after implementation.
Conclusion: The revision has had a number of consequences. First, patients now can meet case criteria without admission to a hospital. To maintain accurate reporting, surveillance systems should place greater emphasis on out patient clinics and private physicians' offices. Second, revised definition cases who succumb before meeting old definition criteria merit special attention. Third, estimates of future cases need to reflect the revision. The increased sensitivity of the revised definition must be taken into account by those planning for future resource needs of AIDS patients.

T.A.P.78 EFFECT OF THE CDC REVISED DEFINITION ON AIDS CASE REPORTS IN NEW JERSEY

Costa, Samuel; Grant, Christine M.; Beil, J.; Massey, J.; Ryan, J.; Robeson, L.
New Jersey State Department of Health, Trenton, NJ, U.S.A.

Objective. To determine the effect of the September, 1987 revision of the CDC surveillance definition of AIDS on case reports received by the New Jersey State Department of Health (NJSDOH).
Methods. Information on AIDS cases newly reported to the NJSDOH in the time period prior to the definition revision (Time I - May 1986-August 1987) were compared to those reported between September 1987 and December 1988 as retrospectively reclassified reports were excluded.
Results. During Time II, there were 2,617 case reports received, 46% of all cases ever reported in the State; 1,091 reports were received during Time I. There were significant differences (p .01) in the composition of reported cases during the 2 time periods. The proportion of females reported during the 2 time periods increased from 19% to 23%; blacks increased from 48% to 53%; heterosexual IVDAs increased from 47% to 55%; homosexual/bisexual males decreased from 32% to 25%. The proportions of Hispanics (13%) and children reported (3%) did not differ. Fully half of all reported cases in Time II were classified due to the new definition, with over 23% associated with wasting syndrome or HIV encephalopathy, and a decline in the proportion of PCP from 63% to 47%.
Conclusions. There have been significant changes in the reported cases of AIDS since the definition revision, most of which seem associated with an increasing number of IVDAs being reported. The proportion of heterosexual IVDAs, women, and blacks, has increased. In half of these cases, these reports would have been excluded during Time I, as OIs not previously included were diagnosed.

T.A.P.79 RETROSPECTIVE REVIEW OF NON-AIDS REPORTS IN NEW JERSEY BASED ON CDC REVISED SURVEILLANCE DEFINITION OF 1987

Coye, Molly; Costa, S.; Yaeger, D.; Ryan, J.; Massey, J.; Beil, J.
New Jersey State Department of Health, Trenton, N.J., U.S.A.

Objective. To determine the significance of the September, 1987, revision of the CDC surveillance definition of AIDS on previously reported suspected AIDS cases, which could not be classified as AIDS under the 1985 definition.
Methods. Reports of suspected AIDS received by the New Jersey State Department of Health (NJSDOH) prior to September, 1987, which could not be classified as AIDS had been classified as AIDS Related Complex (ARC)—a reportable condition in the State— or lacked suitable information to be classified. A file and/or medical record review was conducted on 1,781 such reports received between May, 1985 and August, 1987.
Results. A total of 713 (40%) of the reviewed cases were reclassified as AIDS, based on the revised definition. This represents an increase of 20% over previously reported AIDS cases in New Jersey through September, 1987. Of 1,431 ARC reports reviewed, 666 (47%) were now considered AIDS, and 47 (13%) of the 350 other reports were likewise reclassified. Nearly two-thirds of these 713 reclassified cases involved 3 opportunistic infections: 26% reported presumptively diagnosed PCP, 32% reported wasting syndrome, and 8% reported HIV encephalopathy. In all, 40% reported a previously required OI diagnosed presumptively, 44% reported a newly added OI, and 16% were found to now meet the requirements of the 1985 definition.
Conclusion. A substantial number of the reviewed reports were reclassified as AIDS. Research involving historical case counts need to consider these results and their implications, as case reports based on the previous definition will grossly underestimate the extent of severe clinical manifestation of HIV infection.

T.A.P.80 THE EFFECT OF THE REVISED AIDS 1987 CASE DEFINITION ON THE CHARACTERISTICS OF CASES REPORTED IN UPSTATE NEW YORK

Coles, F.*; Smith, Perry**; Caouette, J.**; Putnam, D.**; Chiarello, L.**; Morse, D.**.
*Centers for Disease Control, Atlanta, Georgia, USA.
**New York State Department of Health, Albany, New York, USA.

Objective. To compare the characteristics of AIDS cases meeting criteria for the 1987 revised case definition only (87CD) with those meeting the old 1985 case definition (85CD).
Methods. Data were obtained from the state registry of upstate AIDS cases and limited to cases diagnosed between 10/1/87 and 12/31/88.
Results. Of 965 cases diagnosed in this period, 285 (30%) met the revised case definition. The percentages of cases who were females (87CD=16%;85CD=14%) and minorities (87CD=56%;85CD=50%) were minimally increased; age distributions were similar. The 87CD group demonstrated increases in the rate ratios (RR) for intravenous drug use (IVDU) among adult cases (RR=1.6;95%CI=1.3,1.8) for maternal IVDU associated with pediatric cases (RR=2.7;95%CI=1.1,6.6) and for the adult case fatality rate (87CD=37% vs 85CD=28%;RR=1.3;95%CI=1.1,1.7). Of the 285 87CD cases, 187 (66%) were presumptive and 98 (34%) definitive. Preliminary follow-up of 52 87CD cases diagnosed between 10/87 and 1/89 showed 4 cases (8%) subsequently met the 1985 definition.
Conclusion. Use of the 1987 revised AIDS case definition has led to increases in females, minorities, IVDU's and in the case fatality rate. Although 30% of cases met the revised definition, the actual increase in case reporting may be less as suggested by the observation that some cases convert to the old case definition with time and by changes in medical practices which may have resulted in an increase in presumptive diagnoses.

T.A.P.81 CAN THE INFECTION RATE OF HBV SERVE AS A PREDICTOR OF HIV INFECTION?

E. Ben-Porath*, A. Etzioni**, Y. Satinger*, N. Rimon*, S. Pollack**, *Virology Unit and ** Div. Clinical Immunology, Rambam Medical Center, Faculty of Medicine, Technion, Haifa, Israel.

Objective. To compare HIV and HBV infection rates in various risk groups for HIV infection.
Methods. Serum samples were collected from 123 hemophilia patients, 49 homosexual men and 32 drug abusers. All samples were tested for anti-HIV antibodies, HBsAg, anti-HBc and anti-HBs.
Results.

Risk Group	HBV+		HVB-		Total	
	No. tested	%pos	No. tested	%pos	No. tested	%pos
Hemophilia	105	52	18	0	123	41
Homosexuals	15	6.7	34	0	49	2
Drug Abusers	25	24	7	0	32	22

There is a significant difference in HIV rate of infection between HBV+ and HBV- individuals in all 3 risk groups. None of 59 HBV- sera was found positive for anti-HIV while 57/145 (39%) of HBV+ sera were also positive for HIV.
Conclusion. Populations at risk for HIV infection are also at risk of infection with HIV. The infection rate of HBV, which is more easily transmitted than HIV, can serve as a predictor for HIV infection rate. Presently, hemophilia patients with very high rate of HBV infection (85%) were also highly infected by HIV (41%), drug abusers with a high rate of HBV infection (78%) were highly infected by HIV (22%) while in the homosexual men population a much lower rate of HBV infection (31%) was associated with a low infectivity rate of HIV (2%).

T.A.P.82 DECLINING INCIDENCE OF ACUTE HEPATITIS B AMONG DRUG USERS IN AMSTERDAM MAY INDICATE A CHANGE IN RISK BEHAVIOR

Bardoux, C.; Buning, Ernst; Leentvaar-Kuijpers, A.; Verster, A.; Coutinho, RA.
Municipal Health Service, Amsterdam, The Netherlands

Objective. To evaluate the AIDS-preventionprogramme among drug users (DU) in Amsterdam with the incidence of acute hepatitis B (AHB) as a surrogate marker.
Methods. AHB-cases in Amsterdam are notified to the municipal health service (MHS) and for each case background data (including possible drug use) are gathered with a interview. All drug users involved in a methadone programme (MP) are reported to the MHS. The estimation of DU not participating in a MP is based on the number of DU arrested by the police. The probability of arrest is considered to be the same for MP and non-MP DU. The number of exchanged needles/syringes is used as a criteria for the preventionprogramme among DU.
Results.

	1983	1984	1985	1986	1987	1988
AHB cases among DU	17	26	24	11	13	5
Estimated number of DU	7900	9300	7800	7400	8200	±8200
AHB incidence among DU per 100,000	216	278	309	149	159	62
Exchanged needles x 1000	-	25	100	400	700	650

Conclusion. The decrease of AHB-incidence among DU may indicate that a significant change in risk behavior has occurred among this group in Amsterdam.

T.A.P.83 FEAR OF AIDS AND INCIDENCES OF GONORRHEA, SYPHILIS AND HEPATITIS B, 1982-88.

Judson, Franklyn; Cohn, D.; Douglas, J. Denver Public Health, Denver, Colorado, USA

Objective. To compare incidences of gonorrhea, syphilis, and hepatitis B as measures of changing sexual behavior resulting from fear of AIDS.
Methods. Yearly incidences of gonorrhea and syphilis in Denver Metro STD Clinic patients, and of hepatitis B in Denver residents were determined for gay men (GM), heterosexual men (HM), and heterosexual women (HW) for 1982 through 1988.
Results.

Year	Gonorrhea (No.)			Syphilis (No.)			Hepatitis B (No.)		
	GM	HM	HW	GM	HM	HW	GM	HM	HW
1982	1,809	1,260	636	138	48	40	22	21	16
1983	1,149	1,255	681	106	45	15	22	18	10
1984	897	1,407	720	101	59	29	34	32	16
1985	785	1,456	753	55	60	21	26	35	15
1986	270	1,340	658	52	52	12	18	44	21
1987	166	984	391	59	87	44	13	35	41
1988	92	789	313	20	111	49	9	19	18

During the 6 year AIDS epidemic in Denver, gonorrhea incidence in GM has declined 95%, but in HM and HW peaked in 1985, then declined 46% and 58% respectively. Syphilis incidence has declined 86% in GM, but recently has increased in HM and HW. Hepatitis B has decreased each year since 1984 in GM and in 1988 in both HM and HW.
Conclusions. Owing to high incidence, short incubation, easy detection, and quick cures, gonorrhea is the most accurate indicator of recent changes in sexual behavior. Syphilis and hepatitis B are much less useful because of low incidence, long incubation, subclinical infection, and, for hepatitis B, non-sexual transmission. GM and white, but not black or Hispanic, HM and HW continue to reduce their risk of HIV infection.

Transmission hétérosexuelle (partie 1)
Heterosexual Transmission (Part 1)

T.A.P.84

CHANGING SEXUAL BEHAVIOUR IN THE 1980'S

Rekart, Michael L. STD Control, Ministry of Health, Vancouver, B.C., Canada.

Objective To examine trends in reported cases of gonorrhea and infectious syphilis in British Columbia from 1980-1988 as a surrogate marker for high-risk behaviour.

Methods Reports of gonorrhea and infectious syphilis were examined from 1980 to 1988 and total cases were compared with cases occurring in homosexual males. In order to 'control' as far as possible for an increase in under-reporting - the same trends were examined in a large metropolitan VD Clinic.

Results

Table I	1980	1981	1982	1983	1984	1985	1986	1987	1988
Gonorrhea-Total	10,144	9,220	8,623	6,137	6,359	5,556	3,564	2,942	1,928
Gonorrhea-Homosexual	1,246	1,244	1,099	678	521	280	132	120	67
% Homosexual	12.3	13.5	12.7	11.0	9.5	5.7	3.7	4.1	3.5
Syphilis-Total	234	190	234	183	149	224	157	88	55
Syphilis-Homosexual	154	130	175	136	100	114	20	15	17
% Homosexual	65.8	68.4	74.8	74.3	67.1	50.9	44.6	17.0	30.9

There were similar trends noted in the Vancouver VD Clinic.

Conclusion Risky sexual behaviour in the 1980s has decreased substantially in British Columbia, probably initiated by the attention surrounding herpes in the early years and intensified by AIDS in the later years. This change has been equally dramatic in the gay community. Information and education on STDs and AIDS is effective in changing sexual behaviour to stop new transmissions of HIV, gonorrhea, and syphilis.

T.A.P.85

AIDS PATIENTS WITH NO IDENTIFIED RISK--LACK OF EVIDENCE FOR NEW MODES OF TRANSMISSION

Conley, Lois*; Bush, T.* and Chamberland, M.*
*Centers for Disease Control, Atlanta, GA, USA

Objective. To identify new or unrecognized modes of HIV transmission.

Methods. AIDS patients with no identified risk (NIR) for HIV exposure are investigated by health departments using a standard protocol.

Results. As of January 1, 1989, investigations have been completed for 1,971 adults initially reported with NIR. Risk factors were identified for 1,632 (83%) persons. Of the 2,662 adults who remain with NIR (3% of all adult cases), 1,854 (70%) are still under investigation; 469 (18%) died, refused interview, or were lost to follow up; and 339 (13%) had no risk identified after investigation. Like heterosexual contact patients and IV-drug users (IVDUs) with AIDS, most (65%) of the 339 investigated adults with NIR were black and Hispanic; the sex distribution was similar to that of IVDUs with AIDS (22% women, 78% men). Interview data were available for 228 (67%) of the 339 investigated adults. Blood exposure via needlesticks was reported by 16 (36%) of 45 health care workers. Other possible parenteral exposures to blood were reported by 9% of the interviewed adults (12 had tatoos and 3 had acupuncture). Illicit non-IV drug use, excluding marijuana, was reported by 22%. One third reported a history of a sexually transmitted disease, and 46 (32%) of 142 men reported sexual contact with a prostitute.

Conclusion. NIR patients have demographic characteristics similar to those of other heterosexual AIDS patients; follow-up of these patients suggests possible sexual or blood exposure to HIV.

T.A.P.86

THE RELATIONSHIP BETWEEN MALE CIRCUMCISION AND HIV INFECTION IN AFRICAN POPULATIONS

Bongaarts, J.*; Reining, Priscilla**; Way, P.***; Conant, F.P.****
*The Population Council, N.Y., **American Association for the Advancement of Science, Washington,D.C., ***The US Bureau of the Census, Suitland, MD, ****Hunter College, N.Y.U.S.A.

Objective. To examine the relationship between HIV seroprevalence and the proportion of uncircumcised males in African countries to determine whether circumcision practices play a role in explaining the large existing variation in the sizes of African HIV epidemics.

Methods. A review of the anthropological literature yielded estimates on circumcision practices for 409 African ethnic groups from which corresponding national estimates were derived HIV seroprevalence rates in the capital cities were used as indications of the relative level of HIV infection in 37 countries.

Results. The correlation between these two variables in the 37 African countries was high ($R=0.9$; $P<0.001$). This finding is consistent with existing clinic based studies that indicate a lower risk of HIV infection among circumcised males.

T.A.P.87

HIV-1 INFECTION IN SEXUALLY EXPOSED WOMEN: RISK FACTORS FOR PREVALENT AND INCIDENT INFECTIONS

FRANCIS A. PLUMMER*, PEPIN J.***, MAITHA G.* MOSS G.****, NDINYA-ACHOLA J.*, D'COSTA L.***.
University of Nairobi*, Nairobi City Commission **, Nairobi; University of Manitoba***, Winnipeg; University of Washington****, Seattle ,WA, U.S.A.

OBJECTIVE: To determine risk factors for HIV-1 infection in women and the incidence of male-female transmission of HIV-1.

METHODS: 238 randomly selected women presenting to a sexually transmitted diseases (STD) clinic were interviewed about sexual behaviour, past STD, contraceptive use, parenteral exposures and examined for STD and HIV infection. HIV seronegative women (HIV-) with genital ulcers (GU) were followed for 6 months.

RESULTS: 30 (12.6%) of women were HIV seropositive (HIV+). HIV+ women were more often single (19/30 vs 55/208, OR=4.8, p<.01), recently prostitutes (6/30 vs 4/208, OR=12.8, $p<10^{-6}$), had a greater mean number of sexual partners in the past 3 months (SP3M) (HIV+ 4±6 vs HIV- 1±3, p<.001), had more past GU (7/30 vs 16/208, OR=3.6, p<.01), past STD (7/30 vs 9/208, OR=2.7, p<.05). Among women with >2 SP3M 6/12 HIV+ vs 7/33 HIV- (p=0.7) reported recent oral contraceptive VS 2 of 33 HIV- women with GU seroconverted.

CONCLUSION: HIV+ is associated with degree of sexual activity, past GU and STD. In Nairobi, 25% of men with GU are HIV+: a crude male-female transmission rate after one sexual exposure of 25%.

T.A.P.88

HIV TRANSMISSION IN STABLE SEXUAL PARTNERSHIPS IN KENYA

Moss Gregory B.*,***, D'Costa LJ.**, Plummer FA.*,**** Cameron DW.****, Ndinya-Achola JO.*, Kreiss JK.***.
*Univ. Nairobi, Kenya; **Nairobi City Commission, Kenya; ***Univ. Washington, Seattle, USA; **** Univ. Manitoba, Winnipeg, Canada.

OBJECTIVE: To identify the frequency of and risk factors for heterosexual transmission of HIV within couples.

METHODS: HIV+ individuals attending a Nairobi STD clinic were enrolled in a prospective study along with their spouse.

RESULTS: Of 75 couples, 35(47%) were concordant (CON) for HIV infection. Of 40 disordant (DIS) couples, in 24 the index case was male and in 16 the index case was female. HIV- women more frequently lived in a city different from their spouse than HIV+ women (9/24 vs 7/61 p=.01). HIV seropositivity was not significally associated with past genital ulcers, injections, blood tranfusions, scarification, circumcision, oral contraceptive use, or number of sex partners. CON and DIS couples were similar with respect to presenting diagnosis, frequency of sex, sex during menses, sex with prostitutes, and CDC stage of HIV disease. Compared to CON women, DIS/HIV+ women were more often single (7/16 vs 2/35 p=.004), more often had a history of STD (11/16 vs 7/35 p=.002), and reported a shorter duration of stable partnership (2.8 vs 7.8yrs p<.001) and a greater number of sex partners since 1980 (4.7 vs 2.5 p<.05). In follow up of 25 couples for a mean of 3.8 months (range 1-18), 3 seroconversions occurred.

CONCLUSION: A high proportion of couples were concordant for HIV. The incidence of new infections is higher than that observed in North American studies.

T.A.P.89

HIV INFECTION AND CIRCUMCISION STATUS

Surick, Ilona; McLaughlin, M; Chiasson, M; et al., New York City Department of Health, NY,NY U.S.A.

Objective. To examine the relationship between HIV infection and circumcision.

Methods. An analysis of two studies done in New York City's Sexually Transmitted Disease(STD) Clinics. Study #1 is a case-control study of 352 men attending 2 STD clinics from 8/87-3/88. Study #2 is a cross-sectional study of 1374 men attending 2 STD clinics from 12/86 to 12/88. All study participants were interviewed. Circumcision status was determined by self-report(both studies) and by physical exam in Study #1.

Results. The prevalence of circumcision by physical exam in Study #1 was 39.1%. In Study #2 the prevalence of circumcision by self-report was 52.0%. The differences in circumcision rates can be explained both by the racial compositions of the two studies and by misclassification in the self report group. Men in Study #1 who were uncircumcised were twice as likely to misclassify themselves as those who were circumcised(17.7% vs 8.4%). The prevalence of HIV infection in Study #1 was 18.2%, and in Study #2 was 13.2%. Logistic regression analysis adjusted for age, race, homosexuality, number of sexual partners, drug use, diagnosis and circumcision status(physical exam and self-report) was done for both study populations. There was no association between circumcision status and HIV infection.

Conclusions. In two studies in NYC STD clinics, with a total of 1726 men, no independent relationship was found between circumcision status and HIV infection.

T.A.P.90 HIV RISK FACTORS IN STEADY MALE SEX PARTNERS OF KINSHASA PROSTITUTES

Nzila, Nzilambi*; Laga, M.***, Kivuvu, M.*; Manoka, AT.*; Mwungura, G.*; Ryder, R.*/**; *Projet SIDA, Kinshasa, Zaire; **CDC, Atlanta, GA, USA; *** Institute of Tropical Medicine, Antwerp, Belgium.

Objectives. To determine HIV infection rate and associated risk factors among steady male sex partners of prostitutes.
Methods. As of January 1989, 77 steady male sex partners of female prostitutes (who participated in a study of STD and HIV) were interviewed, examined and tested for HIV and syphilis.
Results. 8 out of 29(27.6%) male partners of HIV(+) women were HIV(+) vs. 4 out of 48(8%) male partners of HIV(-) women (p(.001) 3(3.9%) of the men had active syphilis and 6(8%) had a history of syphilis. HIV(+) and HIV(-) men did not differ regarding age (31 yrs vs 33 yrs), transfusions (0 vs 3%) or contacts with other prostitutes (16% vs 29%). Characteristics of couples of HIV(+) prostitutes and their steady male partners (HIV(+) or HIV(-)) were compared:

	F(+) M(+)	F(+) M(-)	P value
Male characteristics:			
Always condom use	8%	6%	NS
Circumcision	100%	97%	NS
Syphilis (TPHA+)	25%	0	0.02
Female characteristics:			
History of ulcer (last 5 years)	87%	33%	0.01
Cervical erosion	37.5%	19%	NS

(F=female, M=male, (+)=HIV(+), (-)=HIV(-))

These characteristics were similar for duration of relationship (26 mos. vs 22 mos.) and mean number of sex contacts per week (1.6 vs. 2.7).
Conclusion. A high HIV infection rate is found among steady partners of female prostitutes who have high prevalence of HIV and other sexually transmited disease. Genital ulcer disease in the woman and history of syphilis in the men were risk factors for HIV infection.

T.A.P.91 SEROLOGIC CONCORDANCE AND INCIDENCE OF HIV IN REGULAR SEXUAL PARTNERS IN NAIROBI, KENYA

D. William Cameron*, M. L. Kosseim**, D. Oduor**, L. J. D'Costa**, G. M. Maitha**, G. M. Irungu**, M. Braddick***, A. R. Ronald***, F. A. Plummer***; *Ottawa General Hospital, Ottawa, ON, Canada; **University of Nairobi, Nairobi City Commission, Nairobi, Kenya; ***University of Manitoba, Winnipeg, MA, Canada.

Objective. To identify serologic concordance and correlates of acute HIV infection among regular sexual partners.
Method. Persons referred to a dermatovenerology clinic were screened for HIV antibody in studies, on request or as indicated with consent. Sexual contacts of HIV positive persons had clinical, microbiological and serologic evaluation initially and in monthly follow-up. Marital couples were informed and counselled about HIV and sexual transmission, and provided condoms.
Results. During a one year period, 82 couples were observed. 42 (51%) were initially serologically concordant for HIV antibody. Concordance was not statistically significantly associated with HIV related disease. Duration of sexual relationship was associated with concordance (p<0.05). 40 (49%) partners were initially seronegative. Without subsequent unprotected intercourse, seroconversion occurred in 7/35 (20%), in association with clinical and/or microbiologic evidence of other sexually transmitted diseases (p<0.05).
Conclusion. Classic sexually transmitted diseases may facilitate heterosexual HIV transmission between regular sexual partners.

T.A.P.92 POTENTIAL ROLE OF SPERMATOZOA IN THE TRANSMISSION OF HIV

Elisabeth Dussaix*, D. Guetard**, A Ellrodt***, M. De Almeida****, M. Hadchouel***, A. Auroux****
* Laboratoire de Virologie - C.H.U. de Bicêtre - 94275 FRANCE
** Laboratoire d'Oncologie Virale - Institut Pasteur - Paris - FRANCE
*** INSERM - Unité 56 - C.H.U. de Bicêtre - FRANCE
**** Laboratoire de Biologie de la Reproduction - C.H.U. de Bicêtre - FRANCE

Objective : To further elucidate the mechanism of the sexual transmission of HIV, we investigated whether spermatozoa from healthy men could be infected in vitro by HIV.
Methods : Fresh motile spermatozoa separated from mononuclear cells and seminal plasma, were obtained by swim-up from 12 HIV antibody negative men. In 14 experiments, they were incubated at 37°C for one hour with HIV and then, washed trice in RPMI 1640 containing 10 fetal bovine serum. They were cocultured with normal activated peripheral blood mononuclear cells. In 3 experiments they were preincubated with and without anti DC4 antibodies. Presence of HIV was assayed by detection of reverse transcriptare activity (R.T.A.) in supernatants.
Results : R.T.A. was detected in all cultures by day 9 to 11. Similar results were obtained after preincubation of spermatozoa with CD4 antibodies.
Conclusion : These results indicate that HIV can at least bind to human spermatozoa by non specific membrane absorption. These in vitro results also suggest that artificial insemination of non infected women with isolated spermatozoa from their HIV infected husband may prove dangerous.

T.A.P.93 ETHNIC DIFFERENCES IN THE HETEROSEXUAL TRANSMISSION OF HIV IN CALIFORNIA.

Padian, Nancy*, Moreno, A.*, Glass, S.*, Shiboski, S.*, Maisonet, G.**. *University of California, San Francisco, **California AIDS Leadership Committee, California, USA.

Objective: To examine disproportionate rates of heterosexual transmission of HIV in nonwhite women.
Methods: We examined heterosexual transmission of HIV in the female sexual partners of men infected with HIV or diagnosed with AIDS or ARC, and compared transmission rates and associated risk factors in three ethnic groups: black, latino, and white. Both partners in couples examined were of the same ethnic group. 165 couples were studied.
Results: Black women had slightly higher rates of infection than whites (27% compared to 21%, not significant), whereas latina women had significantly higher rates than whites (46%, p=.04). Both black and latina women were more likely to have intravenous drug users as their index case than white women (p=.0007 and .04, respectively), and latina women practiced anal intercourse with their partners more frequently than either white or black women (p=.004 for each comparison). Increased risk of transmission for latina women disappeared in a logistic regression that controlled for the practice of anal intercourse.
Conclusion: It has commonly been observed that intravenous drug users have higher rates of heterosexual transmission of HIV than infected men from other risk groups. Although nonwhite women in our sample were more likely to have intravenous drug using partners; higher rates of infection among these women can be attributed primarily to higher infection rates among latina women and the more prevalent practice of anal intercourse in this group. These findings remain to be verified in larger more representative samples.

T.A.P.94 HETEROSEXUAL TRANSMISSION OF HIV FROM INTRAVENOUS DRUG USERS TO THEIR SEXUAL PARTNERS.

Padian, Nancy*, Petersen, H.*, Meakin, R.*, Brodie, B.*, Wofsy, C.*, Moss, A*.
*University of California, San Francisco, California, USA.

Objective: To examine the potential for heterosexual transmission from intravenous drug users to their sexual partners.
Methods: Intravenous drug users (IVDUs) who were screened for HIV seropositivity over the last six months in 5 drug treatment centers in San Francisco, were interviewed about sexual partners. If the IVDU was HIV-positive and had heterosexual partners, we recruited their partner for screening.
Results: 330 female and 248 male IVDUs were screened. Approximately 70% returned for their test results. These included 22 seropositive women with male sex partners, and 26 seropositive men with female partners. 20 of the 48 (42%) infected IVDUs could not reach their partners to inform them of their risk. The remaining 28 individuals reported a total of 33 sexual partners. We were able to enroll 10 of these sexual partners, including 5 women and 5 men; 7 (70%) reported IV drug use and all reported having sexual contact with their seropositive partner within the last year. Two of the 10 partners (20%) were HIV positive both of whom were IVDUs.
Conclusion: Many sexual partners of IVDUs experience the double risk of HIV exposure through both drug use and sexual contact with infected persons. A sizable proportion of IV drug users do not return for test results, and of those who do, many are unable to contact their sexual partners. Nevertheless, partner referral at the time of test result notification remains an effective method of reaching individuals who might otherwise be unaware of their risk.

T.A.P.95 STATISTICAL ANALYSIS OF INFECTIVITY BASED ON PARTNER STUDIES

Shiboski, Stephen ; Jewell, N. University of California at Berkeley, Berkeley, California, United States.

Objective. To develop parametric and nonparametric statistical methods for analysis of data on HIV transmission in partners of infected individuals.
Methods. For data on infection status of partners of infected index cases in which number of sexual contacts following infection of the index case is known, a nonparametric estimate of the hazard of transmission is developed viewing number of contacts as a natural time scale and applying discrete survival analysis techniques. In addition, a generalized linear model (GLM) of transmission probability incorporating covariates is developed. The GLM is based on a simple model for transmission which assumes a constant per contact infectivity. Diagnostic procedures are proposed to test validity of the simple model, examine evidence for heterogeneity in infectivity across partnerships and to assess the effect of measurement error in the number of contacts on the GLM estimates.
Results. The methods were applied to data from the California Partner's Study (Padian, et al 1987). The nonparametric hazard estimate indicated that infectivity is not constant for this data, and evidence of heterogeneity was provided by lack of fit of the simple model. In addition, independent contributions to the GLM were observed for condom use (p=.01), bleeding during sex (p=.02), mode of sexual practice (p=.07) and the log number of concacts (p=.001). Similar results were reported by Padian (1989) with another model.
Conclusion. The nonparametric and parametric statistical methods developed provide an effective means of analysis of data on HIV transmission from partner studies and are easily implemented with available software.

T.A.P.96 COMPARISON OF RISK FOR HIV INFECTION AMONG SELF-REFERRED AND PROVIDER-REFERRED HETEROSEXUALS IN A STUDY OF HIV TRANSMISSION

Laufer, D.; Feingold, L.; Zierler, S.; Mayer, Kenneth.
New England Behavioral Health Study, Pawtucket, RI. U.S.A.

Objective. To assess risk for a self-referred population-based cohort compared to a provider-referred group in a prospective HIV transmission study, and to assess efficiency of outreach recruitment in reaching at-risk groups.
Methods. Risk assessment interviews and serologies from the first 215 participants in a prospective study of the heterosexual spread of HIV. Outreach includes TV and radio announcements, newspaper ads, brochures bookmarks, matchbooks, talks on college campuses and informing providers serving populations at risk.
Results. Of the first 215 enrollees, 91 were provider-referred and 124 were self-referred. 41% of the provider-referred participants are HIV+, compared with 7% of self-referreds. Self-referred participants were more likely to be female (52% vs 48%), young (71% in the 18-24 age group vs 55% in the older age groups), and white (61% vs 45% for all other ethnic categories). Self-referreds were almost twice as likely to have had 2 or more partners in the last year, but less likely to know their partners' risk (62% vs 38% of provider-referred did not know their partner(s)' risk). Self-referreds were also more likely to have had 10 or more lifetime partners (56% vs 44%). Self-referred participants were less likely to use condoms (59% reported "rarely" or "never" vs 41% of provider-referred), and were twice as likely to consider themselves at no or slight risk for HIV infection (67% vs 33%).
Conclusion. Self-referred enrollees are less likely to perceive themselves at risk but may be, due to having multiple partners of unknown risk status, and not practicing safer sex.

T.A.P.97 HETEROSEXUAL BEHAVIOR AND HIV STATUS IN A COHORT OF PERSONS AT INCREASED RISK FOR HIV INFECTION

Mayer, Kenneth; Zierler, S.; Feingold, L.; and Laufer, D.
New England Behavioral Health Study (NEBHS), Brown University, Providence and Memorial Hospital, Pawtucket, RI, USA.

Objective: To correlate heterosexual activity and hiv status in a cohort from a region where almost ½ of the new PWA's are heterosexuals.
Methods: Cross-sectional analyses of interviews and serologies from the first 215 enrollees of a community-based prospective study of the heterosexual spread of HIV in S.E. New England.
Results: 22/109 (20%) of the women and 24/106 (23%) of the men were HIV+. 40/46 (87%) of the HIV+ subjects and 39% of the whole cohort are or were IVDU 81% of the cohort is White. Other results included:

Behavioral Parameters	HIV+ Men N=22	HIV+ Women N=24	HIV- Men N=87	HIV- Women N=82
Same sex contact in the past year	8%	5%	5%	1%
> 10 partners in the past year	13%	10%	10%	2%
≥ 50 lifetime partners	32%	54%	14%	32%
History of STD (ever)	63%	50%	28%	30%
Sex with known high risk partners	67%	50%	40%	44%
No condom use in the past	20%	37%	50%	49%

Conclusion: Although 77% of the HIV- subjects perceived themselves to be at increased risk to develop AIDS, > ½ had unprotected sex with known high risk partners in the past year, usually steady, non-paying partners. Most of the HIV+ subjects in this cohort are IVDU, but many who are HIV- knowingly engage in unsafe sex. Risk reduction programs may have to target couples and do more than identify risky behaviors.

T.A.P.98 HETEROSEXUAL TRANSMISSION OF HIV: A EUROPEAN STUDY.
I: MALE-TO-FEMALE TRANSMISSION.

De Vincenzi Isabelle*; Ancelle-Park R.* for the European Community Study Group. * WHO Collaborating Centre on AIDS, Paris, France

OBJECTIVE: To determine risk factors of male-to-female HIV transmission.
METHODS: Between March 87 and October 88, 201 couples were recruited from 6 European countries. Data for HIV(+) males (Index Case=IC) and their heterosexual partners (HP) are collected every 6 months. HP presenting risks for HIV infection other than sexual contacts with the IC were excluded. The cross-sectional analysis of data from the first interview is presented.
RESULTS: Of 201 female HP, 49 were HIV(+). Male IC were mostly IVDU (64%) or bisexual (19%). The following 3 risk factors were identified: practice of anal sex (Odds Ratio=4.2 [1.9-9.6]); male index with full-blown AIDS (O.R.=4.1 [1.3-13.3]); history of sexually transmitted diseases (STD) in the past 5 years for the IC and/or the HP (O.R.=3.0 [1.3-6.8]). Lymphocyte counts were available for 133 male IC. HIV male transmitters (IC+,HP+) had lower %T4 (p=0.02) than non-transmitters (IC+,HP-). Total lymphocyte counts tended to be lower in transmitters but the difference was not significant. P24 antigen test was performed for 102 male IC. The risk linked to a positive test was 1.8 [0.9-6.8]. Duration of relationship (median 3 years), frequency of sexual contacts, sexual practices other than anal sex, and contraceptive behaviour were not found to be associated with partner infection.
CONCLUSION: The great influence of the 3 identified risk factors on male-to-female transmission is shown by differences in HIV prevalence in partners:

	No.couples	%(+,+)		No.couples	%(+,+)
None of the 3 risks	68	5.8%	2 or 3 of these risks	42	50.0%
History of STD for IC and/or HP	54	24.1%	Unknown	5	
Anal-genital sex	24	29.2%			
Male IC: AIDS	8	37.5%	TOTAL	201	24.4%

T.A.P.99

Alberto Saracco, and the Italian Multicenter Study Group on HIV Heterosexual Transmission, Infectious Diseases Clinic, University of Milan, Milan, Italy.

Female steady partners of HIV-infected subjects, without other risk factors for infection, have been enrolled since January 1987 in a study of the role played by behavioral and biological variables in heterosexual transmission of HIV infection. Every HIV positive subjects observed at partecipating centers was considered an index case (IC) and asked about this heterosexual partners. Every partner not already known as HIV infected was invited for screening test and interview. The interview concerned sexual behaviour and contraception in the contacts with IC. previous sexually transmitted diseases (STD) and HBV hepatitis were investigated as well. HIV infection was checked by two immunoenzymatic assays and confirmed by western blot. Data about the IC were collected through medical records. Preliminary analysis on 235 females has confirmed previously reported risk factors such as: history of STD and genital infections and anal sex. Other more controversial possible risk factors such as length of relationship and frequency of sex have been investigated and found, with some limitations, to be associated with HIV transmission. Condon use has been thoroughly investigated and found to be protective. Data on recruited population by May 89 will be presented and discussed, with particular reference to controversial matter.

T.A.P.100 BEHAVIOR MODIFICATION IN COUPLES ENROLLED IN A STUDY OF HETEROSEXUAL TRANSMISSION

Petersen, Heidi*, Padian, N.*, Glass, S.*, Moreno, A.*, Ajanku, I*, Wofsy, C.*

*University of California, San Francisco, California, USA

Objective: To evaluate behavior change in couples who participated in a prospective study of heterosexual transmission.

Methods: We provided education and counseling about safe sex practices as a component of our heterosexual partner study. Participants were evaluated every six months following entry into the study. Behavior at enrollment and last follow-up is compared.

Results: 54 couples were interviewed of which 43 were discordant (index HIV+, the partner HIV-). Amount of sexual intercourse among the discordant couples at last follow-up is as follows: no intercourse = 3/43; less intercourse = 30/43; same amount of intercourse = 3/43; more intercourse = 7/43. Condoms were used by 24/30 of the discordant couples having less intercourse, by 3/3 of those having the same amount of intercourse, and by 5/7 of those engaging in more frequent intercourse. Anal intercourse was practiced by 8 of the discordant couples at intake, only 4 of whom used condoms. Only 2 of these couples continued this sexual practice by the time of last follow-up, both of whom used condoms.

Conclusion: Partner referral and provision of education and counseling in a heterosexual partner study continues to remain an effective vehicle for behavior modification. Failure to practice safer sex resulted primarily from unwillingness, on the part of the partner, to adopt such measures of risk reduction.

T.A.P.101 CHANGES IN SEXUAL AND REPRODUCTIVE BEHAVIOR IN HETEROSEXUAL COUPLES AFTER HIV TESTING

Vogler, Mary; Dugan,T. and Seidlin, M.
New York University School of Medicine, New York, NY, U.S.A.

Objective. To determine the impact of HIV testing on sexual behavior in heterosexual couples, using data from a prospective study of heterosexual transmission.
Methods. Partners (Ps) of infected individuals (Is) were enrolled if Ps had never used IV drugs, had ≥ 10 episodes of vaginal intercourse (VI) with Is, were not separated from and were capable of additional intercourse with Is.
Results: 31 couples were evaluable with a mean duration of follow-up of 12.4 months. Is's were intravenous drug users (23), bisexuals (3), and prior partners of infected heterosexuals (5). 17 Ps were HIV- at entry; none seroconverted during the period of observation. 54% of HIV+ and 25% of HIV- Ps had used non-IV drugs in the year prior to entry. There were no significant differences in marital status, length of relationship, education, or family income between HIV+ and HIV- Ps. All couples were primarily monogamous. All but two reported a change in sexual practices after testing. 4 HIV- and 3 HIV+ Ps became abstinent. The others instituted condom use for VI, but 66% of HIV+ and 40% of HIV- Ps reported inconsistent use. Half of the couples reported anal intercourse (AI) prior to testing; only one couple continued to have AI after testing. Seven Ps were pregnant at the time of their first test, 4 of whom were HIV+. One HIV+ and 3 HIV-s completed the pregnancies. Two pregnancies occurred after HIV testing, both in HIV+s who claimed to be using safe sex practices.
Conclusions: HIV testing of Ps resulted in safer sexual practices, however Ps using condoms for VI did so inconsistently. Because such lapses were especially frequent among HIV+ Ps vertical transmission of HIV remains a persisting risk.

T.A.P.102

HIGH PREVALENCE OF HIV-1 ANTIBODIES IN STD PATIENTS WITH GENITAL ULCERS

Debrework Zewdie.*; Abdurahman, M.**; Ayhunie, S.*; Adal, G.*; Tadesse, M.*; Yemane Berhan, T.***, et al.
* National Research Institute of Health, Addis Ababa, Ethiopia.
** Arada Clinic, Addis Ababa, Ethiopia.
*** ALERT, Addis Ababa, Ethiopia.

Objective. To determine the prevalence of HIV-1 infection in STD patients with genital ulcers.
Methods. Patients attending an STD clinic were randomly selected. Blood specimens were obtained from patients with a past and present history of genital ulcer disease screening for HIV-1 antibody was tested using ELISA (Wellcozyme) and confirmed by Western Blot (BLORAD).
Results. Of the 226 (75 females and 151 males) tested, 63 (27%) were seropositive for HIV-1. The seroprevalence rate in those with past history of genital ulcer disease was 34.7% and 28.6% in patients with gonorhoea.
Conclusion. The high seroprevalence rate is indicative of the role other STDs play in the transmission of HIV infections in hyperendemic STD areas. The prevention of other sexually transmitted diseases and the behavioral change along with this may be one way of curbing the AIDS epedemic in these areas.

Transmission hétérosexuelle (partie 2)
Heterosexual Transmission (Part 2)

T.A.P.103

HIV-1 TRANSMISSION IN HETEROSEXUAL COUPLES

C.Papetti, A.M. Pesce, I.Mezzaroma, E.Pinter, G.D'Offizi, G.Luzi and F.Aiuti

Dept. of Allergy and Clinical Immunology, University of Rome "La Sapienza", Rome, Italy

Objective - To study immunological features and transmission risk in heterosexual couples with one seropositive partner.
Methods - 43 heterosexual couples were evaluated; one partner was seropositive at the first medical check who previously belonged to a high risk behaviour category. The study included 34 seropositive at risk males and 9 females. Number of sexual intercourses, condom use, sexual behaviour, immunological features were evaluated for each couple.
Results - At the first control 17 couples were found to have both positive partners, whereas 26 had seronegative partner not belonging to a risk category. After one year follow up 2 out of 26 seronegatives were infected (77%).
Conclusions - Among the evaluated parameters condom use was found to be important to prevent HIV transmission: 95% of couples with both infected partners did not use condoms, whereas in 62% of couples with one seronegative partner the condom was not commonly applied. Among the immunological parameters CD4+ T lymphocytes and skin tests were found to be relevant biological conditions favouring HIV-1 transmission from a seropositive subject to a seronegative one.

T.A.P.104

PRELIMINARY ANALYSIS OF FACTORS ASSOCIATED WITH SEROCONVERSION IN A STUDY OF HETEROSEXUAL SEXUAL TRANSMISSION OF HIV IN MONOGAMOUS COUPLES

Nichols, Margaret, Paroski P., Sampson G., Leibel J., Kennedy M.J. - Woodhull Medical and Mental Health Center, Brooklyn, NY, USA

Objective. To present a preliminary analysis of factors associated with seroconversion in a study of heterosexual sexual transmission of HIV in a cohort of monogamous couples.
Methods. The Northern Brooklyn Partner Study, begun in September 1988 with funding from the CDC, is a three year longitudinal study of monogamous heterosexual couples in which one partner has as his/her only risk factor sexual contact with the other partner. The sample is drawn from a community based primary health care facility which services a population that is 93% black or Hispanic and 86% IVDU's and their sexual partners. Data gathered are retrospective as well as prospective, and include sexual and drug use behaviors, psychological measures, and medical parameters (stage of disease of index partner, p-24 antigen, HIV cultures, concurrent VD, etc). All subjects are reinterviewed and examined at 3 month intervals.
Results & Conclusions. Preliminary data presented here will be a comparison between couples where sexual transmission has already occurred (concordant couples), and couples where the exposed partner is seronegative at the time of entry into the study (discordant couples). Data will be presented on at least 10 discordant couples, with at least 10 concordant couples used as a comparison.

T.A.P.105

THE RISKS FOR HETEROSEXUAL HIV TRANSMISSION FROM INFECTED BLOOD TRANSFUSION RECEIPIENTS

Ward, John*; Perkins,H**; Donegan, E***; Ou,C-Y*; Laussecq,S+; Gaynor,S++; et.al
*CDC, Atlanta, GA; **Irwin Blood Bank & ***Univ CA. Med. Ctr., San Francisco, CA; +Health Dept. & ++Blood Center, New York, N.Y., USA.

Objective. To identify risk factors for heterosexual HIV transmission.
Methods. HIV-infected transfusion recipients and their partners were asked about sexual practices, medical history, and examined and tested for signs of infection; polymerase chain reaction (PCR) with SK 38-39 primer pairs was used to identify HIV genetic material in peripheral mononuclear cells.
Results. Through 1988, 74 HIV-seropositive recipients were identified and 39 had partners; 5 (19%) of 30 female partners and none of 9 male partners were HIV-seropositive. When tested by PCR, specimens from 26 seronegative partners were PCR-negative; 20 of 24 specimens from seropositive recipients and 3 of 3 from seropositive partners were PCR positive. The 39 recipients with partners had been infected for a median of 60 months (range 11-108 mos.); 14 (36%) had AIDS. Partners of recipients with AIDS were not more likely to be infected compared to other partners (2/14 vs. 2/25). Although compared to uninfected female partners, infected wives tended to be older (58 yrs. vs 50 yrs.), to have fewer sexual contacts (median 84 vs. 186, p=.17), and to more likely bleed after intercourse (1/4 vs. 3/25, p=.46), these differences were not statistically significant.
Conclusion. HIV-seronegative partners had no evidence of occult infection. A recipient having AIDS was not associated with HIV heterosexual transmission. Older age and bleeding after intercourse suggest that age-associated changes in the vaginal mucosa may facilitate HIV transmission.

T.A.P.106

RISK OF HETEROSEXUAL TRANSMISSION OF HIV-1 FROM RECIPIENTS OF BLOOD AND BLOOD PRODUCTS

Transfusion Safety Study Group* represented by Donegan, Elizabeth**.
*Participating institutions, New York City, Miami, Detroit, Seattle, San Francisco, Los Angeles, USA, **University of California, San Francisco, California, USA.

Objective. To assess the potential for transmission of HIV-1 by persons infected by contaminated blood, to heterosexual contacts before and after learning about their status.
Methods. The Transfusion Safety Study is a longitudinal study of recipients of blood and blood products. Information concerning sexual behavior prior to and at 6-month intervals after enrollment was obtained by interview and evaluated for anti-HIV-1 (+) subjects.
Results. 522 anti-HIV-1 (+) subjects probably infected through blood reported one or more heterosexual contacts between 1979 and enrollment. This potential sexual exposure of others included prostitutes (20 subjects). After informed of positivity, 387 of 469 with follow-up continued to have sexual contacts. Of these, 80 (21%) reported that they were sexually active with multiple partners. Two (10%) of 21 anti-HIV-1 (+) primary sexual partners also continued having sex with additional partners.
Conclusion. Transfusion-transmitted HIV-1 infections, although responsible for a small percentage of all infections, increase the reservoir in the community and the potential for further transmission through heterosexual contact. (Sponsored by Contract No. N01-HB-7003 of the National Heart, Lung, and Blood Institute.)

T.A.P.107

NO MORE SEROCONVERSIONS AMONG SPOUSES OF PATIENTS OF THE BONN HEMOPHILIAC COHORT STUDY.

Kamps, Bernd.S.*; Niese,D*; Brackmann,H.H.**; Euler,P.**; van Loo,B.**, Kamradt,T.***
*Universitätsklinik Bonn, FRG, **Institut für experimentelle Hämatologie, Bonn, FRG, ***Massachusetts Institutes of Technology, Cambridge, MA, U.S.A.

Objective. To evaluate the risk of heterosexual HIV-transmission.
Methods. In 1986, 150 HIV-negative female partners of HIV-positive hemophiliacs were informed about possible transmission risks and enrolled in a prospective study. Both Elisa and Western Blot were performed at intervalls of 6 to 12 months.
Results. 7 couples stopped having sexual contact. Regular condom use was reported by all but 6 of the remaining couples. On one occasion, one woman had a borderline Western Blot result which was not reproducible. All other women always tested negative.
Conclusion. Barrier contraceptives used in monogamous relationships seem to be efficient in preventing heterosexual HIV-transmission.

T.A.P.108 REAL VALUE OF SERONEGATIVITY IN LONG-TERM-EXPOSED SEXUAL PARTNERS OF HIV-INFECTED HEMOPHILIACS

Picchio,G;Bouzas,María Belén;Mathov,I;Muchinik,G;Pérez Bianco, R;Anselmo,A.
IIHEMA,Academia Nacional de Medicina,Buenos Aires,Argentina.

Objective. To investigate,using a sensitive virus culture method,whether seronegativity in females(spouses of HIV Ab pos.hemophiliacs)(hem) was due to undetectable Ab levels or was really reflecting absence of infection.
Methods. Virus culture was performed on PBMCs from:Group(G)A:2 hem with AIDS; GB:5(2 hem, 2 female-sexual partners and 1 newborn)asymptomatic HIV-pos individuals; GC:2 hem with PGL. Four sexual partners were defined as asymptomatic HIV Ab-neg individuals who had maintained a monogamous sexual relationship with an HIV Ab-pos hem for a minimum of 2 years without the use of barrier contraceptives. Virus culture was also performed on 2 low-risk HIV Ab-neg individuals. HIV Antigen (Ag) (Abbott) presence was tested in all samples.
Results. From GA, both individuals resulted culture-pos (100%), only 1 Ag pos. From GB, 4 out of 5 resulted culture-pos (80%). From GC, both individuals resulted culture-pos (100%), only 1 being Ag pos. The 4 sexual partners as well as the 2 neg controls resulted both culture- and Ag neg.
Conclusion. Absence of infection (Ab neg) can be confirmed in the 4 sexual partners which resulted virus culture-neg, Ag neg. The Ag capture assay proved to be less sensitive than virus culture (2 out of 8 pos cultures) (25%).

T.A.P.109 RESULTS OF HIV ANTIBODY TESTING IN SEXUAL PARTNERS OF SEROPOSITIVE HEMOPHILIACS OVER A 5 YEAR PERIOD

Forsberg, A.D.*, Sullivan, J.L.**, Willitts, D.L.**, Kraus, E.* and Brettler, D.B.*
*New England Hemophilia Center, Worcester Memorial Hospital and **University of Massachsuetts Medical Center, Worcester, Massachusetts, U.S.A.

Objective: To determine the rate of serconversion among sexual partners of hemophiliacs tested between September, 1984 and January, 1989.
Method: 75 sexual partners of 73 HIV antibody positive hemophiliacs were identified over a five yr. period. 69 of the hemophiliacs were requested to inform their partners about confidential HIV antibody testing done at the New England Hemophilia Center (NEHC). 7 refused to inform their partners (9 partners), 5 partners refused testing, 5 partners were lost due to death of the hemophiliac or divorce, 43 agreed to be tested at NEHC and 9 revealed their test results performed at an alternate test site. Of the 52 tested, 31 were tested at least twice (range 1 to 8 tests) and 30 had their initial or most recent test done since July, 1987. Medical Records were examined to determine clinical status, presence of antigenemia and CD4 cell level of the hemophilic partner.
Results: 51 out of the 52 tested (98%) were HIV seronegative. This group includes the sexual partners of 9 hemophiliacs with AIDS, 4 with p24 antigen positivity and 8 with CD4 cell levels ≤ 200 cells/ul. One spouse was seropositive at time of first testing in 1985. At the time of her positive test, her hemophiliac husband had no clinical illness or antigenemia and a CD4 cell level of 996 cells/ul.
Conclusion: In this group of sexual partners it appears the rate of transmission is low and the rate as not apeared to increase as hemophiliacs deteriorate clincally and immunologically. This rate may be lower than in other clinics in the U.S. The reasons for this are not clear. Extensive counselling regarding safer sex practices begun in 1985 may be a factor in this lack of serconversion among sexual partners.

T.A.P.110 HETEROSEXUAL TRANSMISSION OF HIV-INFECTION FROM HEMOPHILIACS TO THEIR SPOUSES

Detlef Niese*, T.G.A.Kamradt*,B.S.Kampe*, K.E.Schneweis**,P.Euler***, H.H.Brackmann***
* Department of Internal Medicine ** Institute for Clinical Microbiology *** Institute for Experimental Hematology, Hemophilia Center ,University of Bonn ,Bonn, Federal Republic of Germany

Objective: To determine rate and cofactors for heterosexual transmission of HIV-Infection in hemophiliacs.
Methods: 176 female and one male partner of HIV-seropositive hemophiliacs were examined serologically. 13 infected as well as 39 uninfected partners have been examined clinically and immunologically. Regarding the index cases, 12 transmitters and 119 non-transmitters have been examined.
Results: 18 female and one male partner (12%) were anti-HIV-positive in ELISA and Western blot analysis until september 1st 1988. 86 have been retested in until january 1st 1989, no additional seroconversions have been observed.All infected partners have stage CDC II-III disease. In 17/39 seronegative partners CD8+ counts were >700/µl.Regarding the index cases, CD4+ counts are significant lower in transmitters than nontransmitters. Virus isolation was successfull in 6/11 transmitters and 11/60 non-transmitters. In 308 hemophiliacs, who have been examined at least twice, the CD4+ count is declining by 110±19/µl/year.
Conclusions: Low CD4+ counts, successfull virus isolation,and p24 antigenemia are important risk factors for heterosexual transmission of HIV in hemophiliacs. Additional factors will be discussed.

T.A.P.111 TRANSMISSION HETEROSEXUELLE DE L'INFECTION VIH CHEZ LES PARTENAIRES DE TOXICOMANES VIH-SEROPOSITIFS (VIH+).

Errante, Isabella; Orso M.*; Meini M.*; Caggese L.; Ferrazzi D.; Schlacht I.
Hôpital Niguarda Ca' Granda-Milan. * Bureau d'Hygiène de la ville de Milan, Italie.

Objectif. Evaluer le risque de transmission hétérosexuelle de l'infection VIH et l'efficacité des mesures de prévention chez les partenaires habituels de toxicomanes VIH+.
Méthodes. Entre décembre 1985 et décembre 1988 on a déterminé la sérologie VIH chez les partenaires hétérosexuels habituels (relation de couple supérieure à 6 mois), sans facteurs de risque connus sauf la contamination sésuelle de 103 toxicomanes VIH+. Le test a été effectué par méthode ELISA et par Western Blot. Ensuite on a contrôlé 34 partenaires VIH - tous les 6 mois, pendant une période d'un minimum de 12 à 30 mois. A tous les couples on a conseillé l'usage du préservatif.
Résultats. Dans 91 cas le partenaire toxicomane VIH+ était un homme (85 asymptomatiques, 4 LAS, 2 ARC), dans 12 cas une femme (11 asymptomatiques, 1 ARC). Au premier test aucun partenaire masculin n'était infecté, tandis que 10 femmes, partenaires de toxicomanes VIH+ asymptomatiques, résultaient séropositives. Seulement 34 partenaires VIH- se sont soumis à la surveillance sistématique de la sérologie VIH. Vingt-huit couples ont utilisé régulièrement le préservatif, 6 couples, au contraire, non. Dans ce dernier groupe on a observé 2 séroconversions (33.3%) au cours de 12 mois.
Conclusions. Les toxicomanes VIH+ peuvent représenter une source importante de contamination par voie hétérosexuelle, indépendamment du stade clinique de l'infection VIH, surtout à cause des résistances à l'utilisation du préservatif.

T.A.P.112 RISK FACTORS FOR HIV-1 INFECTION IN STD CLINIC PATIENTS: EVIDENCE FOR CRACK-RELATED HETEROSEXUAL TRANSMISSION

Chiasson, Mary Ann*; Stoneburner RL*; Telzak E* **; Hildebrandt D*; Schultz S*; Jaffe H***. *New York City Dept. of Health, NY, NY., **Memorial Sloan-Kettering Cancer Center, NY, NY, *** CDC, Atlanta, GA. U.S.A.

Objective. To evaluate heterosexual transmission of HIV-1 in STD cilinic patients in an area of New York City where the cumulative incidence of adult AIDS is 44.5/10,000 and drug use including crack (cocaine) is common.
Methods. Volunteers enrolled in an ongoing study beginning 1/88. HIV-1 antibody was measured and data on demographics and sexual and drug use behavior were collected by an interviewer using a structured questionnaire.
Results. HIV-1 INFECTION BY RISK AND GENDER (N=1041)

RISK	MEN HIV+	(%)	N	WOMEN HIV+	(%)	N
Gay/Bisexual	37	(37)	99	-	-	-
IV Drug User (IVDU)	36	(44)	82	17	(55)	31
Sex Partner Person at Risk (SP)	17	(14)	122	13	(11)	115
No Identified Risk (NIR)	12	(3)	440	6	(4)	152
TOTAL	102	(14)	743	36	(12)	298

NIR HIV+ men were more likely (8/12) to report prostitute contact than HIV- men (174/428), O.R.=2.2, p=.07; 1/12 was a crack user and 3/12 had sexual contact with known crack users. NIR HIV+ women were more likely to be crack using prostitutes (4/6) than were HIV- women (3/146), O.R=95, p<.001.
Conclusions. Although most HIV-1 infection in this population occurred in gay/bisexual men, IVDU, or their heterosexual partners, sexual behavior associated with crack use may be related to transmission among persons who deny other AIDS risk factors (NIRs).

T.A.P.113 TRANSMISSION OF HIV INFECTION IN HETEROSEXUAL PARTNERS OF HIV+ DRUG ADDICTS.

Perroni Luigi,Le Foche L.,De Stefano G.,
De Longis P.,Albertoni F.and Soscia F.
Dept.of Infectious Diseases, Latina General Hospital, Latina,Italy

Objective. To evaluate the prevalence and incidence of HIV infection in heterosexual partners of HIV+ i.v. drug addicts (d.a.) with no other known risk factor.
Methods .The sexual partner of each HIV+ d.a. attending our out patient clinic was tested every six months by commercial ELISA kits (Abbot) ;positive results were confirmed by Western Blot (W.B.).Advice on effective means of prevention of sexual transmission of HIV was given to each couple.
Results.Thirteen of 60 monogamous partners ,52 F and 8 M, of an equal number of HIV+ d.a. (3/5 partners of Aids cases,8/40 of LAS/ARC and 2/15 of asymptomatic subjects were found positive when first tested .The seronegative partners were followed for a median of 12 months but none seroconverted .Of the 47 couples with a negative member,35 couples used condoms while 12 used no preventive measure during the follow up period as evidenced by 5 pregnancies.
Conclusions .Our data confirm the importance of heterosexual transmission of HIV infection; the absence of seroconversion observed can be explained by the short period of follow up .Moreover the tests used are not able to evidence the early stages of infection .

T.A.P.114 INCREASING IMPORTANCE OF HETEROSEXUAL TRANSMISSION OF HIV DUE TO IVDU IN CATALONIA

Casabona,Jordi(*),Salinas R(**),Tor J(***) ,Garcia T (*) and Campillo N (*).
(*) Epidemiology Section. AIDS Program. Generalitat de Catalunya. Barcelona.
(**) H.Creu Roja, Barcelona.(***) H.Germans Trias, Badalona,(Spain)

Objectives: 1.- To describe the evolution of heterosexually acquired AIDS cases in Catalonia. 2.- To describe the characteristics of index cases of patients infected through heterosexual contact.
Methods: Data from the population-based registry of Catalonia were used to identify all AIDS cases with heterosexual contact as the reported route of infection. After validation of this information the characteristics of their possible index cases were recorded, when possible. Data from an on-going study on risk factors for heterosexual HIV transmission were also used for this purpose.
Results: In contrast with data from Spain as a whole, until 1986 the majority of AIDS cases in Catalonia were found among homosexual men, but afterwards IVDU became the first group. In 1986 heterosexually acquired AIDS cases accounted for 1.9% of all cases diagnosed during that year, in 1987 5.5% and in 1988 3.5% (but probably underestimated because of the delay in the reporting). Nine of 12 cases were confirmed as heterosexually transmited AIDS cases, 4 men and 5 women. Two men have had sexual contacts with IVDU women, and 2 women had a IVDU heterosexual partner. We studied 104 stable heterosexual partners of HIV infected patients, with no other known risk factors. Seventeen (16.4%) of them were also HIV infected. All index cases (12 men and 5 women) were IVDU.
Conclusions: After the introduction of HIV infection among IVDU of our community, an increase of heterosexual and vertical transmitted AIDS cases has been observed. In all of the selected HIV positive couples, the index case has been an IVDU patient. Preventing the spread of HIV among young IVDU seems to be the best way of decreasing heterosexual and vertical transmission of HIV in our population.

T.A.P.115 TRANSMISSION OF HIV INFECTION IN HETEROSEXUAL PARTNERS OF HIV INFECTED DRUG ABUSERS.

A.Chirianni, M.D'Abbraccio. P.Tullio Cataldo, S.Noce, L.Picciotto, M.Piazza.
Clinic of Infectious Diseases University Naples-Italy.

Objective. To determine rates and risk factors of heterosexual transmission of HIV.
Methods. From January 1985 to December 1988, 83 drug abusers who were anti-HIV positive (index case =IC) and their respective heterosexual partners (HP) were studied. Only couples who reported a stable sexual relationship for at least 12 months and in which the HP did not present other past or present risk factors were included in the study.
Results. In the 83 couples studied 74 of the HP were women between the ages of 17 and 32 and 9 were men between the ages of 21 and 33. 15/74 women (20.2%) and 1/9 (11.1%) for a total of 16/83 (19.3%) were found to be seropositive, 14 at the first control. 28 of the HP who were negative at the first control were followed for 6-48 months (mean 14.4 months). Seroconversion occurred in 2 cases (6 per 100 subjects/year). No case of seroconversion were observed in 10 HP followed for 67 months (mean 7 months) whose IC partner was being treated with Zidovudine. 2/20 (10.0%) HP of asymptomatic IC, 7/45 (15.5%) HP of IC with PGL, 1/7 (14.2%) HP of IC with ARC (CDC group IV A) and 6/11 (54.4%) HP of IC with AIDS were positive. Heterosexual transmission was associated with very low (<100) T4 cell counts (P<.001) and with positivity for HIV-Ag in the IC (P<.001). Length of relationship, frequency of sexual contacts, anal intercourse, oral sex and genital diseases were not significantly associated with HIV infection.
Conclusions. Clinical stage of the IC, low T4 cell counts and HIV-Ag positivity are factors which significantly influence heterosexual transmission of HIV. Treatment of IC with Zidovudine considerably reduces the probability of HIV infection in the respective HP.

T.A.P.116 ABSENCE OF HIV TRANSMISSION THROUGH CASUAL CONTACTS IN FORMER DRUG USERS

Alessandro Zanetti, A.Gringeri, G. Zehender, F.Tradati, A.Boschini and M. Colombo, Institutes of Internal Medicine and Virology, University of Milan ,Milan, Italy

Objective: to study whether HIV can be transmitted through casual contacts. Methods: between 1985 and 1988, anti-HIV was measured by ELISA at six month intervals in 686 residents in the S.Patrignano Community (Rimini). During residence (median 25 months), former drug users were forced to be off drugs and, except for 25 married couples, had no sexual contacts,either. 307 seronegative drug users and 37 staff members were not exposed sexually to the 293 seropositive residents (72% stage II, 17% stage III and 11% stage IV, CDC) for a median of 19 months (6-44). All residents were using and cleaning the same facilities, such as toilets, restaurant, medical and dental clinics and kindergarten. Results: there were no cases of HIV seroconversion during follow-up. Conclusions: HIV was not spread through casual contacts in this Community for drug users. Therefore, seronegative drug users were safely enrolled with seropositive individuals in our rehabilitation programs based on Community residence.

T.A.P.117 ANAL INTERCOURSE: A RISK FACTOR FOR HIV INFECTION IN FEMALE PARTNERS OF BISEXUAL MEN, RIO DE JANEIRO, BRAZIL.

Sion, Fernando Samuel*; Morais de Sá, C.A.*; Rachid de Lacerda, M.C.*; Rubini, N.P.M.*; Quintães, E.P.*; Castilho, E.A.**
* Gaffrée & Guinle University Hospital - University of Rio de Janeiro (UNI-RIO) - Brazil
** FIOCRUZ

Objective: To evaluate the association between anal intercourse and male-to-female HIV transmission.
Methods: Among 176 women at risk for HIV infection, 131 (74,4%) were female partners of bisexual men infected by HIV. We analized their sexual life, social and demographic characteristics. We excluded women who had any history of intravenous drug abuse or blood transfusion. The association between modes of intercourse was assessed statistically by Chi-Square test and the 95% confidence limits of the odds ratio were stimated by Cornfield's Method.
Results: Data are presented in the following table:

MODE OF INTERCOURSE	ANTI-HIV ANTIBODIES REACTIVE n (%)	ANTI-HIV ANTIBODIES NON REACTIVE n (%)	TOTAL
VAGINAL / ANAL	36 (62 %)	22 (38 %)	58
VAGINAL ONLY	18 (24,7 %)	55 (75,3 %)	73

χ^2 = 17,158 P < 0.0001 OR = 5,00 [2,22 - 11,44]

Conclusion: Anal intercourse represents a risk factor 5 times greater then vaginal intercourse in female partners of bisexual men.

T.A.P.118 HIV-1 IN PATIENTS WITH GENITAL LESIONS ATTENDING A NORTH AMERICAN STD CLINIC: ASSESSMENT OF RISK FACTORS.

Whittington, W.L.*; Jacobs, B.*; Lewis, J.*; Lee, F.**; Edwards, T.**; Nahmias A.**. *Centers for Disease Control and **Emory University School of Medicine, Atlanta, GA, USA.

Objective. To assess risk factors associated with HIV-1 infection.
Methods. Patients (n=177) with genital lesions were tested for antibodies (Ab) to HIV-1, HSV type 2, and T. pallidum (RPR confirmed by FTA-ABS). Lesion specimens were examined by darkfield microscopy and cultured for herpes simplex viruses (HSV).
Results. Lesions were due to HSV (54%), syphilis (7%), non-venereal dermatoses (8%), and other/unknown (31%). Antibodies to HIV-1, HSV type 2, and T. pallidum were detected in 13 (7%), 106 (60%), and 24 (14%) individuals, respectively. Infection with HIV-1 was associated with a reactive RPR (RR 7.4 [3.5-18.2, 95% CI]), but not with current syphilis. Among all men, Ab to HIV-1 was associated with homosexual/bisexual preference and lack of circumcision (3.5 [1.2-10.6]). HIV-1 infection was not associated with initial HSV genital lesions; high prevalence of Ab to HSV type 2 in this cohort limited analysis. In heterosexuals, Ab to HIV-1 (7 [4%] of 167 patients) was associated with reactive RPR (5.8 [1.6-21.3]) and in men, lack of circumcision (8.4 [1.4-50.1]). In heterosexual men, lack of circumcision was associated also with Ab to HSV type 2 (1.4 [1.0-2.0]) and reactive RPR (2.8 [1.1-7.2]).
Conclusion. Associations were found between Ab to HIV-1 and syphilis Ab and lack of circumcision. The later may indirectly increase risk for HIV-1 acquisition by increasing the likelihood of acquiring ulcerative genital lesion diseases such as herpes and syphilis.

T.A.P.119 GENITAL HERPES AS A POSSIBLE RISK FACTOR FOR HIV TRANSMISSION

Nahmias,André*; Corey,L.***; Lee,F.*; Clumeck,N.****; Cannon, R.**; Holmberg, S**; et al. *Emory University and **Centers for Disease Control, Atlanta, GA, USA; ***University of Washington, Seattle, WA, USA and ****St. Pierre University Hospital, Brussels, Belgium

Objective: To review the evidence for a role of genital herpes and herpes simplex virus type 2 (HSV-2) infection as a risk factor for HIV transmission.
Methods: Detailed review of relevant studies in 2 homosexual populations in the U.S. and 3 heterosexual populations in Africa, Haiti and the U.S.
Results and Conclusion: Such studies require HSV-2 antibody testing, since most genital herpes cases are asymptomatic. However, the prevalence of HSV-2 antibodies is so high in sexually active populations throughout the world (4 to 10X greater than for syphilis antibodies), that large study numbers are required. This high prevalence of HSV-2 infection suggests that, if HSV-2 does increase HIV acquisition, the population attributable risk would be expected to be great, particularly in Western countries where other causes of genital ulcers are much less frequent. The correlation between prevalence of HSV-2 antibodies and sexual behavior patterns makes a biological role for HSV-2 difficult to prove. Nevertheless, both prospective and case-control studies, which accounted for other measures of sexual activity, still demonstrated a higher prevalence and, in one study, incidence of HSV-2 in HIV+ individuals. So far, current studies suggest that HSV-2 may increase the risk of susceptible individuals to acquisition of HIV. Although the reverse is also likely, studies,such as those in couples, are needed to test this hypothesis. Recently initiated intervention studies for HSV-2, as well as further prospective, case-control, biological and immunological investigations are needed to define more fully the nature and extent of the HSV-2/HIV associations.

T.A.P.120 EPIDEMIOLOGY OF HIV INFECTION IN HONG KONG

E.K. Yeoh, P.C.K. Li, W.L. Lim, Y.Y. Chan, S.H. Lee.
Medical and Health Department, Hong Kong.

Materials and Methods: Between April 1985 to December 1988, a seroepidemiological study was performed to assess the prevalence of HIV infection in Hong Kong. Blood specimen were first screened with a commercially available ELISA test and repeatedly positive results were confirmed by immunofluorescence and Western Blot methods.
Results: 134 of 114,624(0.117%) specimens were positive by all three techniques. 130 samples were from males and 4 were from females.

Results of HIV
Serological Screening

Source of Referral	No.Tested	No.(%)+ve
STD Clinics		
Male patients	76522	12(0.016%)
Female patients	18251	0(0 %)
Female prostitutes	6909	0(0 %)
IV Drug Abusers	3139	0(%)
Haemophiliacs	163	53(32.5 %)
Health Care Personnel	540	0(0 %)
Semen Donors	152	0(0 %)
Government Clinics	7219	38(0.53 %)
Private Clinics	1721	3(1.8 %)
Total	114624	134(0.117%)

Risk Factors in HIV
Seropositive Individuals

	AIDS	No.AIDS	Total
Homo/Bisexual	10	42	52
Heterosexual	2	10	12
Transfusion	0	3	3
Haemophiliac	1	52	53
IV Drug Abusers	0	2*	2
Unknown	3	9	12
Total	16	118	134

*IV drug abuse outside Hong Kong.

Conclusion: Haemophiliacs, homosexuals and bisexuals, and heterosexuals with sexual contact with prostitutes constitute high risk groups for HIV infection in Hong Kong. Since August 1985, a donor screening programme had been started in the transfusion service in Hong Kong and only donor-screened heat-treated clotting factor concentrates were used for the treatment of haemophiliacs. Although HIV infection had not yet been detected among the local IV drug abusers, they remain potentially at risk. Intensive health education campaign has been in progress to inform the public of the role of sexual exposure and IV drug abuse in the transmission of HIV

Prévalence du VIH chez les femmes et les enfants
HIV Prevalence in Women and Children

W.A.P.1

SEROPREVALENCE OF HIV ANTIBODIES IN NEONATES AND CHILDREN

Bigler, W.*; Wilder, M.*; Manoff, S.**; Patti, J.*; Fenn, Shannon*; Witte, J.*; et al.
*Department of Health and Rehabilitative Services, Tallahassee and Miami, Florida, USA, **CDC, Atlanta, Georgia, USA.

Objective: To assess the magnitude and scope of HIV Infection in neonates and young children from low socio-economic populations in Miami, Florida.
Methods: Between 5/20/88 and 1/11/89, 2941 children in two age groups (0-6 Weeks and 15-24 Months) attending Public Health well-baby clinics for routine examination, were also blindly screened for HIV antibodies by EIA and confirmed by Western Blot.
Results: Demographic characteristics of the mothers and HIV test results of their neonates/children are as follows:

Variable	Neonates (0-6 weeks)	Children (15-24 months)
Mothers age	13-49 yrs (median 28)	17-50 yrs (median 30)
Mothers race	Hispanic 47%,blk/Hai 42%	Hispanic 44%, blk/Hai 45%
All HIV +	12/1672 (0.7%)	4/1269 (0.3%)
90% CI	(0.4%-1.2%)	
blk/Hai HIV +	12/735 (1.6%)	3/605 (0.5%)
90% CI	(1.0%-2.7%)	

Conclusion: These results suggest that between 100 and 270 of the approximately 10,000 black and Haitian neonates born in Miami during 1989 will be exposed to HIV. The rate for 15-24 month old black and Haitian children (0.5%/1.6%) is similar to other studies that suggest approximately 30% of those children born to HIV seropositive mothers will be infected.

W.A.P.2

ROUTINE HIV ANTIBODY SCREENING IN LOS ANGELES COUNTY PRENATAL CLINICS: A DEMONSTRATION PROJECT

COHEN, WENDY*; Mascola, L.*; Giles, M.*; Bauch, S.*; Finn, M.*; [illegible], C.*
*Los Angeles County Department of Health Services; Los Angeles, California, USA.

Objectives. 1. To offer HIV antibody (AB) screening to all pregnant women as a means of primary prevention and/or early detection of pediatric AIDS. 2. To evaluate a model program of HIV testing for pregnant women using universal screening and culturally sensitive education materials.
Methods. Five Los Angeles County (LAC) Health Centers are participating in a pilot project to offer optional HIV antibody testing as part of routine prenatal care, starting in January 1989. A bilingual (English/Spanish), multi-item consent form was developed, incorporating 7 routine prenatal laboratory tests along with HIV. Patients received pre-test counseling and informed consent for HIV testing in the form of an 8-minute bilingual video tape shown in group education sessions during their first prenatal visit. HIV AB testing is done at LAC public health laboratory using ELISA, with immunoflourescent antibody and western blot as confirmation of repeat ELISA positives. HIV AB positive pregnant women are counseled individually and then interviewed to assess previous high risk behavior. Positive women are referred to a tertiary center for continued prenatal care.
Results. 1. Preliminary results show that 285 pregnant women, (n=355), consented to HIV testing, giving an acceptance rate of 85%. 2. Of 170 HIV antibody tests performed to date, one woman is positive. The patient is 18 years old, single, black, 31 weeks pregnant and denies all high risk behavior for both herself and her partner.
Conclusion. 1. The acceptance rate for HIV AB testing in LAC prenatal clinics is high, reflecting general acceptability of the format of presentation of the HIV test. 2. We recommend universal prenatal screening for HIV AB, as HIV positive women frequently do not acknowledge high risk behavior, and may not be detected in programs targeting only high risk individuals.

W.A.P.3

EPIDEMIOLOGY OF HIV INFECTION IN WOMEN FROM FRANKFURT AREA

Staszewski S., Schieck E., Rehmet S., Odewald J., Müller R., Helm E.B., Stille, W.
Universitätsklinik Frankfurt, Zentrum der Inneren Medizin, Infektiologie, Th.-Stern-Kai 7, 6000 Frankfurt/M, Federal Republic of Germany

Objective: To investigate the spread of AIDS in women from Frankfurt area.
Methods: Epidemiological and clinical examination of 317 HIV-positive women of HIV outpatient clinic Frankfurt.
Results: The no. of HIV-infected women increased from 2 (1984) to 21 (1985), 102 (1986), 103 (1987) to 91 (1988). In the years mentioned, the female proportion of all HIV-infected patients was 4%, 13%, 26%, 27%, and 25%. 74% were drug addicts, 22% got infected through heterosexual contacts, 2% through blood or coagulation factors, resp., 2% had no known risk. The proportion of heterosexually infected patients increased from 14% in 1985 to 29% in 1988. At the same, time, proportion of drug addicts decreased from 100% to 69%. 38% of drug addicts and 9% of heterosexually infected women were prostitutes. 10 of 63 heterosexually infected women are Africans; in 23% male index persons were drug addicts, in 16%, bisexuals, in 10%, hemophiliacs, and in 8%, Africans. For the rest, risk of male index partners was not known. 77% women were asymptomatic, 6% had AIDS. Most common opportunistic infection was PCP (65%). Remarkable was the occurrence of Kaposi's sarcoma in 2 cases.
Conclusion: The no. of HIV-positive women in the Frankfurt area has increased significantly since 1985. The increase in heterosexually infected women is most remarkable.

W.A.P.4

EPIDEMIOLOGY AND OUTCOME OF HIV SEROPOSITIVE CHILDREN IN MADRID COMMUNITY.

* M.D. Gurbindo Gutierrez; ** R. Bueno; *** J. Herrera; **** M. Moro; ***** F. Omeñaca; ****** J. Ruiz et al.
* H. G. Gregorio Marañón; ** Regional Health Service; *** H. Cruz Roja; **** H. Clinico S. Carlos; ***** H."La Paz"; ****** H. 12 de Octubre. MADRID SPAIN.

Since 1988 the Madrid Regional Health Service has required, every six months, a report of all cases of HIV seropositive (HIV+) children of Madrid Hospitals. Up to the present date the reports at Feb. 1988 and at Jun 1988. have been studied.

In Feb. 1988, 205 HIV seropositive children were reported (ELISA and Western Blot), aged between 0 and 16 years, the 60% were males. Risk factors for HIV transmission were: 80% HIV+ parents; 13% hemophiliacs; 1.5% blood transfusion. Children were clinically classified (CDC 1987) into: P-0 143; P-1 32 and P-2 30.

In Jun. 1988, 202 children were reported, classified into P-0 125; P-1 30 and P-2 47. In that period (Feb-Jun.) 69 new HIV seropositive children were found. Fifty there children became seronegative, 43 before 15 months old and the remaining after this age. Fourteen were lost during the follow up. There were 5 deaths, 3 out 5 without direct relation to AIDS. All children with hemophilia were included into P-2 status. Twenty one out for 202 children lived in public institutions. The last reports (Dic. 88) are presently analysed.

W.A.P.5

NEWBORN SCREENING FOR HIV ANTIBODY SEROPOSITIVITY IN THE SOUTH BRONX.

Bland, I.L., Checola, R.T., Wiznia, Andrew, Kim, M.H., Noble, L.M., Yoon, J.J.. Albert Einstein College of Medicine, Bronx, New York, USA.

Objective. HIV antibody seropositivity (HIV +) was studied anonymously in a group of healthy (n=84) and critically ill newborns (n=96) in the South Bronx, N.Y. a socioeconomically disadvantaged area, to obtain incidence data and identify risk factors in this high risk population.
Methods. Histories and physical exams were performed on all newborns, matched with cord blood samples, and anonymously coded before screening for HIV antibody using an ELISA with Western blot confirmation.
Results. The incidence of HIV+ in healthy newborns without a history of maternal drug abuse was 6.0%. The incidence of HIV+ in newborns admitted to the neonatal intensive care unit (NICU) was 12.5%. There were significant differences between the HIV+ and HIV- NICU groups for incidence of smallness for gestational age (33% vs 2.4%, $p<.001$) and microcephaly (25% vs 1.2%, $p<.005$). Maternal drug abuse as defined by a positive history and/or urine toxicology was found in 66% of HIV+ and 27% of HIV- infants, <p.02.
Conclusion. There is an alarmingly high incidence of HIV+ in our screened population. Growth failure and microcephaly appear to be related to HIV+ either through effects of the virus on the fetus or associated factors such as maternal drug abuse. The fact that 34% of our HIV+ NICU population and none of our well baby population had a maternal drug history implies an increasing percentage of perinatal AIDS may be transmitted by heterosexual contact rather than by maternal drug usage. This study highlights the need for universal HIV screening in high risk areas to ensure the best health care for these infants.

W.A.P.6

HIV Risk Factor Prevalence Among Young Women of Child-Bearing Age Attending Women's Primary Care Clinics

Harris, N.V.*; Wood, Robert W.*; et al.
*Epidemiology Unit, Seattle-King County Dept. of Public Health, Seattle, WA U.S.A.

Objective: To estimate the HIV risk factor prevalence among women of childbearing age.
Methods: In December 1988, we asked clients of 3 Seattle-area women's clinics to complete anonymous questionnaires regarding their age, race, sexual activity, condom use, IV drug and needle use and transfusion history.
Results: The first 384 participants were young (age≥14,median=22) mostly white(85.7%), unmarried(76.0%), and of low family income (range=$0-$59,000, median=$12,500). Reasons for the clinic visit included "Birth control"(68.8%), "Pregnancy test"(17.2%), "Sexually transmitted disease (STD) check"(9.4%), "Prenatal care"(6.3%), "AIDS test"(2.9%) and "Other"(20.8%). Of these 384 women, 145(37.8%) reported sex with multiple partners (number of partners, range=2-10, median=3), and 172(44.8%) with casual partners in the past year. Among those reporting sex with casual partners, 131(76.2%) either "seldom" or "never" used condoms. Also, since 1978, 186(48.4%) had at least one STD, 40(10.4%) had an intravenous drug using (IVDU) or bisexual male sex partner, 20(5.2%) disclosed IV drug use, 17(4.4%) shared needles, and 23(6.0%) had sex for drugs or money. By contrast, for the past 12 months, merely 8(2.1%) disclosed IV drug use and 11(2.9%) shared needles. Only one woman indicated that her partner was HIV positive. We will present these and early 1989 data to profile women who are practicing behaviors which place them at risk for HIV infection.
Conclusions: Clients of Seattle women's clinics have taken significant risks with regard to HIV acquisition: unprotected sex with multiple/casual partners.

W.A.P.7 HERPES SIMPLEX, SYPHILIS, AND HEP B: ASSOCIATION WITH HIV-1 AND HTLV-I IN PREGNANT HAITIAN WOMEN

Boulos, Reginald*; Halsey, N**; Ruff, A**; Adrien, M*; Quinn, TC**; Nahmias, A***; et al****.
*Centers for Health and Development, Port-au-Prince, Haiti, **Johns Hopkins University, Baltimore, MD, USA, ***Emory University, Atlanta GA, USA, ****Centers for Disease Control, Atlanta, GA and National Cancer Institute, Bethesda, MD, USA

Objective. To determine associations of HIV-1 and HTLV-I infections with herpes simplex types 1 and 2, syphilis, and hepatitis B in pregnant women residing in a periurban slum.
Methods. Pregnant women were screened for HIV-1 and HTLV-I and a weighted sample was selected for further antibody testing.
Results. Percent Positive:

	HIV-1 pos.(n=95)	HTLV-I pos.(n=44)	Neg.(n=89)
Syphilis	21.5%+	14.3%	8.0%
HSV-1	95.8%	97.7%	97.7%
HSV-2	88.4%++	81.8%++	53.4%

+p=0.02, ++p = 0.0001, vs. seronegative women
Based upon the 9.2% seroprevalence rate for HIV-1, approximately 56.6% of pregnant women in this population were HSV-2 seropouitive, similar to inner city populations in other countries.
Conclusion. Both HTLV-I and HIV-1 infections were associated with HSV-2 seropositivity suggesting sexual transmission of these viruses in this population.

W.A.P.8 HIV INFECTION IN PREGNANT WOMEN AT A PUBLIC HOSPITAL IN NEW ORLEANS, LOUISIANA

McFarland, Louise; Dean, H.; Trahan, B.; Muirhead,L.
Louisiana Department of Health and Hospitals, New Orleans, LA, USA.

Objective. To determine the rate of HIV infection among prenatal clients in a public hospital in New Orleans from May 1988 to December 1988.
Methods. Routine HIV counseling was given to all prenatal clients. Clients consenting for testing (CFT) were administered a risk assessessment questionnaire and were categorized as low risk (LR) or high risk (HR) for acquiring the HIV infection. Basic demographic data was collected from each CFT. HIV antibody tests were performed using ELISA and Western blot methods.
Results. A total of 3,908 were counseled. 3,846 (98.4%) clients agreed to be tested, 62 (1.6 %) declined testing. Of clients tested, 2,981 (78%) were black females, 606 (16%) whites and 111 (3%) hispanics. Five hundred twenty-four clients (13.6%) were categorized as high risk and 3322 (86.4%) as low risk. Prevalence of HIV infection in prenatal clients was found to be 20/3846 (0.5%). Of the twenty positive, 16 (80%) were black females and 4 (20%) were whites. Among the high risk clients, 7 (1.3%) were seropositive for HIV. There were thirteen (0.4%) low risk clients testing HIV positive.
Conclusion. These data show that high risk prenatal clients appear to be at a greater risk for testing HIV positive. This study also shows a lower HIV seropositivity rate compared with similar studies in inner-city hospitals. Although the risk assessment questionnaire was used as a method for identifying high and low risk clients, it should not replace the availability of HIV counseling and testing for all pregnant women. Routine HIV counseling and testing should be an important component of total obstetrical screening during pregnancy.

W.A.P.9 THE SEROPREVALENCE OF HIV INFECTION IN NEW YORK CITY CHILDREN.

Weisfuse, Isaac B.*; Thomas, P.*; Oxtoby, M.**; Back, S.*; Stevens, R.***; Berns, D.***; et al.
New York City Department of Health, New York, NY; **Centers for Disease Control, Atlanta, GA; ***New York State Department of Health, New York, NY, U.S.A.

OBJECTIVE. To determine the seroprevalence of HIV infection in selected NYC pediatric populations.
METHODS. Two populations of children were surveyed: children aged 1 to 10 screened in their households by neighborhood teams testing for lead poisoning and 1 to 3 year old children attending pediatric clinics run by the New York City Department of Health. All specimens were collected on filter paper and tested for HIV by ELISA and Western Blot. Both surveys were blinded.
RESULTS. To date, 990 specimens from the lead screening survey have been collected. Results are available on 920. Of these, two children were positive by ELISA and Western Blot (0.2%, 95% C.I. 0.05% - 0.35%) and 2 others ELISA positive and Western Blot inconclusive. In the pediatric clinic survey, 20 of the 55 clinics are being surveyed and approximately 2,000 children tested.
CONCLUSIONS. Based on newborn screening surveys in New York City showing an infection rate among pregnant women of about 1.5%, a seroprevalence of HIV in these children of less than 1% is expected. Furthermore, these surveys demonstrate further uses of the filter paper technology for HIV testing.

W.A.P.10 HIV INFECTION IN LESBIANS.

Ribble, Denise;:Marte, C.; Kelly, J.; Keyes, C.; Rodgers, P.; Wolbert, J.; Bellevue Hospital/Community Health Project, NY, NY, USA.

HIV infection and AIDS is a leading cause of morbidity and death in women aged 25-34 years in New York City. To date, studies have considered only heterosexual and pregnant women in transmission and seroprevalence data.

Lesbian women have not been studied for transmission risk and seroprevalence despite national U.S. AIDS surveillance data indicating 101 cases of AIDS in lesbians.

At a community-based, primary care AIDS assessment clinic and in a support group for women with HIV infection, ARC and AIDS, there are 31 cases of HIVAb seropositivity in lesbians. Their self-reported risk factors for HIV infection are as follows: IVDU-16; prior sexual contact with infected men (by consent, by force or by sperm donation)-7; prostitutes-5; female to female transmission-2 and contaminated transfusion recipient-1.

It is clear that there are lesbians with HIV infection and AIDS, and, it is important to include them in transmission studies and seroprevalence statistics. The false notion that women who define themselves as lesbians are not at risk for HIV infection can lead to tragic misdiagnosis by providers and lack of risk awareness by the women themselves.

W.A.P.11 NO CHANGE IN HIV-1 SEROPREVALENCE AMONG PARTURIENTS AND WOMEN HAVING INDUCED ABORTIONS IN NEW YORK CITY, 1987-1988

Araneta, Maria Rosario G; Thomas, PA; Ramirez, LL; Weisfuse, I; Schultz S; New York City Department of Health, New York, New York, United States

OBJECTIVE To determine the change in HIV-1 seroprevalence in a population based sample of women giving birth and having induced abortions in New York City in 1987 and 1988.
METHODS A repeat serosurvey of a representative sample of 3,556 women giving birth or having induced abortions in 20 obstetric and 15 abortion facilities in NYC from July to December 1987 and July to December 1988 was conducted. Currently, 1988 data are available for 2357 women from 23 facilities and are compared to 1987 data from the same facilities.
RESULTS HIV-1 antibody seroprevalence did not change significantly [1.41% (95% CI: 1.07%-2.03%) vs. 1.53% (95% CI: 1.09%-2.13%), p=0.90] between 1987 and 1988, nor by pregnancy outcome, racial, age, nor payment status categories. Similar to 1987, multiple logistic regression identified receiving Medicaid and being between 25-29 years of age as significantly associated with HIV-1 seropositivity.

	1988 HIV+/Total (%)	1987 HIV+/Total (%)	p-value
Total	36/2357 (1.53%)	34/2357 (1.41%)	0.90
Births	21/1257 (1.67%)	19/1257 (1.51%)	0.87
Abortions	15/1100 (1.36%)	15/1100 (1.36%)	0.85
Medicaid Recipients	12/ 519 (2.31%)	26/ 774 (3.36%)	0.36
25-29 years	11/ 506 (2.17%)	12/ 640 (1.89%)	0.88

CONCLUSIONS HIV-1 seroprevalence among pregnant women remained stable during a one year period in the city with the highest reported incidence of adult female and pediatric AIDS.

Incidence du SIDA
AIDS Incidence

W.A.P.12 THE EVOLVING EPIDEMIOLOGY OF AIDS IN NEW YORK CITY: TRENDS IN AIDS CASE SURVEILLANCE DATA.

Greenberg Alan E.*/**, Thomas PA*, Hindin RH*, Greene AW*, Rautenberg EL*, Schultz SJ*. *NYC Dept of Health AIDS Surveillance Unit, **AIDS Program/CDC, USA.

Objective. To monitor trends in the epidemiology of AIDS in New York City.
Methods. In NYC, AIDS cases are counted through active surveillance conducted by the Dept of Health in collaboration with 77 hospitals. A transmission category is assigned for each case and trends are monitored.
Results. As of 12/88, NYC had reported a total of 18,022 AIDS cases, or 22% of the USA total. Trends in specific categories were assessed.

Transmission	Mean Number of AIDS Cases Diagnosed Monthly in NYC							
Category	1981	1982	1983	1984	1985	1986	1987	1988*
Total	9	43	87	151	224	317	362	394
MWHSWM(1)	6	25	50	88	125	170	170	161
IVDUs(2)	2	10	22	41	68	101	129	165
MWHSWM/IVDUs	1	4	6	7	12	12	14	10
Heterosexuals(3)	0	1	1	3	5	9	12	15
Children <13	0	1	3	4	4	7	8	6

* Through 8/88 (1) Men who have sex with men (2) Intravenous drug users (3) 99% of heterosexual cases represent male to female transmission
Conclusion. NYC continues to serve as an epicenter of the AIDS epidemic in the USA; as of 12/88, the number of cases reported to CDC from NYC (18,022) exceeded the combined total from San Francisco (6,602), Los Angeles (6,010), Houston (2,578), and Newark (2,460). The number of cases diagnosed monthly among total cases, IVDUs, and heterosexuals has increased, whereas the number of cases among MWHSWM appears to have stabilized.

W.A.P.13 THE EPIDEMIOLOGY OF AIDS IN SAN FRANCISCO'S ELDERLY POPULATION

Payne, Susan F.; Wilson, C.; Rutherford, GW. San Francisco Department of Public Health, San Francisco, CA, U.S.A.

Objective. To describe the epidemiology of AIDS among San Francisco (SF) residents aged 60 and older.
Methods. We analyzed the demographics and transmission categories of 5,834 AIDS patients reported to the SF Department of Public Health between July 1981 and December 31, 1988.
Results. 125 (2.1%) of patients were $\geq$ 60 years, corresponding to an incidence of 90/100,000. Of these 125 patients, 107(85%) were 60-69 years, 16(13%) were 70-79 years, and 2(2%) were $\geq$ 80 years. Among patients 60-69 years, 76% were homosexual/bisexual males, 17% were transfusion recipients, and 7% were in other risk groups. Among patients $\geq$ 70 years, 31% were homosexual/bisexual males and 69% were transfusion recipients (p<.001). AIDS patients $\geq$ 60 years were more likely than younger patients to be female (7% vs 1%, p<.001); transfusion recipients (24% vs <1%, p<.001); to have a primary diagnosis other than KS (82% vs 67%, p<.001); and to live outside SF (18% vs 10%, p<.01). Older AIDS patients did not differ from younger patients by race/ethnic group. Among homosexual/bisexual patients, patients $\geq$ 60 years were less likely to be intravenous drug users than younger patients (5% vs 12%, p<.05).
Conclusion. SF AIDS patients $\geq$ 60 years were more likely to be female, transfusion recipients and have a primary diagnosis other than KS. AIDS patients 60-69 years were primarily homosexual/bisexual males, while patients $\geq$ 70 years were primarily transfusion recipients.

W.A.P.14 THE EPIDEMIOLOGY OF AIDS-RELATED NON-HODGKIN'S LYMPHOMA IN SAN FRANCISCO

Lemp, George F.; Payne, S.F.; Neal D.P.; Rutherford, G.W. San Francisco Department of Public Health, San Francisco, California, U.S.A.

Objective. To describe the epidemiology of non-Hodgkin's lymphoma (NHL) in AIDS patients diagnosed in San Francisco (SF).
Methods. We evaluated 5834 AIDS cases reported in SF from 1981 through 1988 with respect to an initial or subsequent diagnosis of NHL. All patients with NHL met the CDC definition of AIDS-indicative NHL. Median survival was calculated using the Kaplan-Meier product-limit method.
Results. 179 (3.1%) AIDS patients were initially diagnosed with NHL. NHL as an initial diagnosis rose significantly (p<0.01) from 1.0% of total cases in 1983 to a peak of 4.3% of cases in 1987, then declined slightly to 3.3% of cases in 1988. These trends do not appear to be a reporting artifact since a significant (p<.05) rise in NHL was also found for patients diagnosed at three active surveillance hospitals where prospective laboratory and medical record review has been conducted since 1983. 238 (4.1%) AIDS patients had NHL at some point during their illness. AIDS patients with NHL did not differ significantly from those without NHL with respect to age, gender, race/ethnicity, risk group, or residence in 19 contiguous census tracts with the highest incidence of AIDS in SF. Median survival for AIDS patients presenting with NHL (6.6 months) was significantly shorter than that for patients without (12.6 months) (p<.001).
Conclusion. NHL has risen significantly as an AIDS-related manifestation. Demographics of AIDS patients with NHL are similar to patients without. Survival is shorter for AIDS patients with NHL.

W.A.P.15 THE AIDS EPIDEMIC IN EUROPE

Ancelle-Park, Rosemary*; Couturier, E.*; Lavoie, G*. and Brunet, J.B.*
* WHO Collaborating Centre on AIDS, Paris, France

Objective. To determine the trends of the AIDS epidemic in Europe.
Methods. Cumulative quarterly surveillance data are collected from 31 European countries. Variations in trends between December 1984 and 1988 are analysed and presented for Europe as a whole and by country.
Results. By December 1988 over 18,000 cases had been reported to the Centre. There has been a yearly 2-fold increase in reported cases between Dec. 1984 and Dec. 1987 and a 1.5-fold increase between Dec. 1987 and Dec. 1988. The rates per million population are highest in Switzerland (106.4), France (101.7) and Denmark (70.2), and lowest in eastern European countries. The overall doubling time of the number of cases reported in Europe is 12.7 months (June 1988). Doubling times have lengthened since the start of the epidemic in all countries except Greece. Distribution of cases by country shows a predominance of the IVDU transmission group reported in the southern European countries and the homosexual group in the northern countries. A continuous increase in the percentage of cases reported in Europe among IVDU is noted: Dec. 84: 1%; Dec. 85: 7%; Dec. 86: 14%; Dec.87: 20%; Dec. 88: 25%. In the global data, variations over time in the distributions of disease categories, age, sex, transmission groups of children's mothers are directly related to this increase.
Conclusion. Doubling times of the number of cases have lengthened since the start of the epidemic. Geographic variations persist, with a majority of IVDU in southern countries. Variations noted in global European surveillance data are directly related to the steady increase in the percentage of IVDU.

W.A.P.16 FOUR-FOLD INCREASE IN TUBERCULOSIS/AIDS PATIENTS IN NEW YORK CITY, 1985-1988

Laroche, Eddy; Araneta, MRG; Stoneburner, RL; Adler JJ
New York City Department of Health, New York, New York, United States

OBJECTIVE To evaluate the prevalence of Tuberculosis/AIDS and to assess its contribution to TB morbidity in New York City (NYC).
METHODS A computer match was performed using culture diagnosed adult cases (age >15) reported to the NYC TB Registry from 1979 through 1988 and CDC defined adult AIDS surveillance cases from 1981 through 1988.
RESULTS A total of 1116 patients with TB/AIDS were identified. TB/AIDS cases increased 4-fold since a similar study was conducted in 1985 wherein 261 patients were identified. The proportion of TB/AIDS as a percentage of AIDS cases between 1985 and 1988 remained fairly stable, from 5.2% to 6.3%, whereas the proportion of TB/AIDS among TB cases increased significantly from 2.2% to 8.1%. The proportion of TB/AIDS cases with IVDU histories or with extrapulmonary TB alone remained stable between 1985 and 1988.

	1979-1988	1979-1985	p-value	O.R.
TB/AIDS/AIDS	1116/17,749 (6.3%)	261/ 4980 (5.2%)	.007	1.21
TB/AIDS/TB	1116/13,820 (8.1%)	261/11,640 (2.2%)	$<10^{-6}$	3.83
% of TB/AIDS				
w/extrapulmonary TB	203/1116 (18%)	58/261 (22%)	.016	0.78
IVDU only	581/1116 (52%)	127/261 (49%)	.357	1.15

CONCLUSION AIDS remains a significant risk factor for clinical manifestation of Tuberculosis in New York City. The proportion of TB/AIDS cases with extrapulmonary TB was less than expected. The increase in TB/AIDS patients is most likely due to the increase in the number of IVDU.

W.A.P.17 EPIDEMIOLOGY OF AIDS-ASSOCIATED LYMPHOMAS: UNITED STATES

Beral, V; Peterman, Thomas A; Berkelman, RL. Centers for Disease Control, Atlanta, GA, USA.

Objective: To characterise patients with AIDS-associated lymphomas and evaluate whether these lymphomas might be due to an infectious agent.
Methods: We reviewed cases of AIDS reported to CDC by 3 December 1988.
Results: A lymphoma considered indicative of AIDS was reported for 2185 (2.7%) patients with AIDS, including: immunoblastic, 1,248 (1.6%); Burkitt's, 474 (0.6%); and primary lymphoma of the brain (PLB), 463 (0.6%). The three types differed in age distribution: No cases of Burkitt's and only one case of immunoblastic were reported in children < 2 years of age but 6 cases of PLB were reported in this age group; all types peaked at ages 5 to 19; after age 25 immunoblastic rose again while PLB and Burkitt's remained constant. In other respects, the distributions of the types of lymphomas were similar. After stratifying by age, heterosexual drug users or cases attributed to heterosexual transmission had rates half that of homosexual men, while men with hemophilia had rates twice that of homosexual men. Lymphomas were twice as common in white as black patients with AIDS in the same age and risk group.
Conclusion: The age differences in AIDS-associated lymphomas are the most striking epidemiologic finding. The other differences could be attributable to differential medical care. If these lymphomas are due to an infectious agent, it does not appear to be sexually transmitted.

W.A.P.18 CHANGING PATTERNS OF HETEROSEXUALLY ACQUIRED AIDS IN FLORIDA

Holtzman, Deborah*; Brandenburg, N.A.**; Sims, J.*; Witte, J.J.*.
*Department of Health and Rehabilitative Services, Tallahassee, Florida, USA;
**University of South Florida, College of Public Health, Tampa, Florida, USA.

Objective. To describe secular trends in heterosexually acquired AIDS in Florida by demographic and risk group characteristics.
Methods. Based on the CDC surveillance definition for heterosexual transmission (HT), secular trends among HT cases in Florida were analyzed over the interval 1980-88.
Results. As of January 12, 1989, Florida reported 567 (9% of total) non-US born HT AIDS cases and 304 (5%) US-born HT AIDS cases. Among men, the proportion of non-US-born HT cases (N=415) decreased from 33 to 5% from 1980-88 (p < 0.001). Among women, the non-US-born HTs declined from 67 to 13% over the same interval (p < 0.001). In contrast, the proportion of US-born HT men (N=141) increased from .6 to 3.5% from 1980-88 (p < 0.001), with a comparable increase among women from 9 to 23% (p = 0.01). The majority (61%) of US-born HT women reported intravenous drug use (IVDU) among their partners. Further, the proportion of female cases attributable to sexual contact with an IVDU increased from 6 to 18% over the interval (p = 0.002). Most (69%) of these women were black; this percentage did not vary significantly over time. Among US-born HT women, no secular trends in age at diagnosis were observed, nor were age differences apparent by race.
Conclusion. The proportion of cases among non-US-born HTs is declining in Florida, while coincident increases are occurring among the US-born HTs. The trends in the US-born HTs do not seem to be influenced by demographic factors at this time. Continued surveillance may help to explain these trends.

W.A.P.19 THE RELATIVE RISK OF AIDS FOR THE BLACK AND HISPANIC COMMUNITIES IN NEW JERSEY

Williams, N.; Cove, Molly; Ryan, J.
New Jersey State Department of Health, Trenton, New Jersey, USA.

Objective. We sought to determine the relative risk of AIDS in New Jersey's population by age, gender, and racial/ethnic group and risk behaviors compared to the U.S. population.
Methods. To measure the relative risk of AIDS in a given age, gender, or racial/ethnic group, we used the cumulative incidence of AIDS for that age, race and gender group, reported to the Centers for Disease Control for a national comparison to the AIDS cases gathered by the New Jersey Department of Health's AIDS Registry. For our analyses the reference group was non-Hispanic U.S. Whites. Case reports from 1981 to November 30, 1988 were included in the analysis. The population of each racial/ethnic group was that reported by the Bureau of the Census of 1980.
Results. Overall, the relative risk of AIDS in NJ for Blacks and Hispanics was 12.4 and 5.8 times as great, respectively, as that in U.S. Whites. The cumulative incidence rates of AIDS for Black and Hispanic men (6960,3577) women (2187,605) and children (402,249) in New Jersey are unmatched by any other populations yet studied in the United States. The greatest risks for AIDS were associated with IV drug abuse.

RELATIVE RISK (Cumulative Incidence)

	IVDA, Men	IVDA, Women	Male IVDA Sex. Part.	IVDA, Mother
U.S. WHITE	1 (33)	1 (10)	1 (3)	1 (1.7)
NJ BLACK	140 (4616)	152 (1520)	148 (444)	162 (276)
NJ HISPANIC	59 (1966)	28 (276)	80 (240)	89 (151)

Conclusion. The differences in the risk for AIDS for various racial/ethnic groups were greatest for heterosexual Blacks and Hispanics in association with IV drug abuse.

W.A.P.21 HETEROSEXUALLY TRANSMITTED AIDS IN NEW YORK STATE

Lehman, Stan*; Smith, P*; Mikl, J.*; Morse D.*
*New York State Department of Health, Albany,New York, USA.

Objective. To describe the demographic characteristics and trends of AIDS cases having heterosexual transmission as their risk factor in NYS.
Methods. We analyzed all AIDS cases attributed to heterosexual transmission in NYS. Cases were defined as heterosexually transmitted if they had no other risk and were born either in the U.S. (US), or in a foreign country (FC) where heterosexual transmission is thought to occur commonly.
Results. As of 12/31/88, 1003 (4.9%) of 20,476 NYS AIDS cases met the definition for heterosexual transmission (623 Heterosexual US and 380 heterosexual FC).The characteristics of these two groups have differed widely. Of the 380 heterosexual FC cases, 76.1% were males and 99.7% were Black. Among heterosexual US cases, 95.6% were females, 40.1% Black, 40.8% Hispanic and 18.3% White. The most common risk factors for the heterosexual US cases were sexual partner of Intravenous Drug Users(IVDU)-83.6%, and sexual partner of bisexual males-8.9%. Since 1981, the proportion of cases that have been heterosexually transmitted has remained steady at about 5%. However, the proportion of total cases attributed to heterosexual US has increased from 1.5% in 1981-83, to 2.6% in 1984-86, to 3.8% in 1987-88.
Conclusion. Though the proportion of heterosexual AIDS has remained constant, the proportion of heterosexual US cases has grown steadily. This has occurred primarily among persons who are sexual partners of IVDU's and parallels the rapidly growing numbers of AIDS cases diagnosed among IVDU's.

W.A.P.23 RISK OF AIDS AND HIV INFECTION IN AMERICAN INDIANS AND ALASKA NATIVES

Conway, George A.*, Hooper EY**, St. Louis ME*. AIDS Program, CDC, Atlanta, Georgia, **Indian Health Service, Phoenix, Arizona, USA.

Objective: To assess available information on the risk of AIDS and HIV infection for American Indians (AI) and Alaska Natives (AN).
Methods: Cumulative race-specific U.S. AIDS case incidence rates were compared with race-specific HIV seroprevalence rates from 1) U.S. military recruit applicants and 2) patients (excluding those with AIDS-, STD- or drug-related conditions) in the CDC Sentinel Hospital HIV Surveillance System.
Results: AIDS Case Cumulative Incidence Through January 9, 1989

Race	Total Cases	Population	Cases/100,000	Relative Risk
AI/AN	89	1,700,000	5.24	0.15
All other	83,142	243,600,000	34.13	1.00

HIV Seroepidemiology Data

Setting	Race	#Positive	#Tested	Seroprev.1,000	Relative Risk
Military	AI/AN	12	9,888	1.2	0.9
Recruits	All other	2,139	1,516,005	1.4	1.0
Sentinel	AI/AN	3	374	8.0	2.9
Hospitals	All other	9	3,226	2.8	1.0

Conclusion: HIV seroprevalence is disproportionately higher for Native Americans compared with other groups than is the cumulative incidence of AIDS in Native Americans. Preliminary data indicate this to be true in men and women. This raises at least two possibilities: 1) widespread racial misclassification in AIDS cases among American Indians and Alaska Natives, and/or 2) more recent entrance of HIV into this population.

W.A.P.20 CHANGES IN MODE OF TRANSMISSION AMONG AIDS CASES IN HOUSTON, TEXAS, USA

Phelps, A.F. and Falletti, Robert L.
Bureau of Epidemiology, Houston Dept. of Health & Human Services, Houston, Texas U.S.A.

Objective: To describe AIDS transmission over time in a high incidence area.
Methods: The Houston area is comprised of six counties with a population of 2.9 million. Passive surveillance reports are received daily from hospitals, physicians and state surveillance programs. Active surveillance reports are obtained by telephoning hospitals, hospital-based surveillance in two hospitals, death certificate review and tuberculosis linelist review. Validation studies are ongoing.
Results: From 1981 to 1988, 2,684 AIDS cases were reported. A dramatic change in percent is seen from diagnosis years 1986-1988 among males whose mode of transmission is IV drug use. Among females, the two modes of transmission showing changes in percent are IV drug use and heterosexual contact.

(Note: 0% = less than 1%)

	YEAR OF DIAGNOSIS								
Transmission	1981	1982	1983	1984	1985	1986	1987	1988	CUM
male - male	88%	89%	71%	87%	85%	81%	81%	76%	81%
IV drug user	-	-	5%	1%	1%	2%	4%	8%	4%
male-male & IV drug user	12%	11%	21%	8%	10%	10%	7%	5%	8%
treat. of hemophilia	-	-	-	-	-	0%	0%	-	0%
male-female/female-male	-	-	1%	1%	0%	1%	1%	3%	1%
transfusion	-	-	1%	1%	1%	3%	3%	2%	2%

Conclusion: While the modes of transmission demonstrate that male-male sexual contact predominates in the Houston area, increases among the IV user group as well as the heterosexual contact group indicates transmission modes in Houston are changing. Examination of modes of transmission over time is important to help target intervention programs.

W.A.P.22 HEPATITIS DELTA(HDV)AND AIDS IN RISK COMMUNITIES IN ARGENTINA

Fay,Oscar* **;Muchinik,G***;Biglione,J**;Bouzas,MB***; Fernández,E* ;Galíndez,J**,et al.
*Centro de Tecnología en Salud Pública,UNR,**Comité Prevención SIDA,Rosario, Santa Fe,***IIHEMA,Academia Nacional de Medicina,Buenos Aires,Argentina.

Objective. To study the evolution of HDV epidemiological penetrance together with HIV's in risk communities, as compared with previously recorded epidemiological data as per population.
Methods.HIV(ELISA),(WB)and HDV(ELISA)serological markers in drug addicts (IVDA),homosexuals(HS) and hemophiliacs(HF) were recorded as at September 30,1988.

Community	HBsAg(+) HIV	NR	Anti-HDV(+) NR	%	TOTAL
IVDA	(+)	34	3	8.8	11(8)
	(-)	136	9	6.7	
HS	(+)	9	2	22	9(19)
	(-)	43	7	17	
HF	(+)	28	4	14	8(12)
	(-)	40	4	10	

Out of 1,168 voluntary HBsAg(+) blood donors,18(1.37%)were anti-HDV-positive until 1984,and out of 345 HBsAg(+) hepatic pathology-patients,7(2%)were anti-HDV-positive.

Conclusion. HDV penetrance in the above risk communities is significantly higher than among healthy and/or HBV-hit carriers. These communities represent an HDV reservoir liable to strike at any time, thus increasing the attack rate on the exposed population. HBsAg control is a way of detecting the risk of catching HDV which should be widely promoted. HBV prevention measures,specially vaccines, must be intensified in the case of health workers into contact with these HIV-risk communities. Detection of HBV-carriers among risk communities will reduce the possibility of catching HDV and, consequently, its propagation.

W.A.P.24 DECLINE IN RATE OF NEW AIDS CASES AMONG HOMOSEXUAL AND BISEXUAL MEN IN SAN FRANCISCO

Lindan, Christina*;Rutherford,G.W.**;Payne,S.**;Hearst,N.*;Lemp,G.**
*Center for AIDS Prevention Studies, University of California, San Francisco, USA;
**San Francisco Department of Public Health, San Francisco, CA, U.S.A.

Objective. To analyze changes in the incidence of reported AIDS cases in homosexual and bisexual men (HBM) in San Francisco (SF).
Methods. We reviewed AIDS cases reported by December 31, 1988 in HBM (including IV drug users) in SF by half-year of diagnosis from 1985 through June 1988, and examined 3 possible causes for a decline in the rate of new cases: late reporting, under-reporting, and a decrease in the proportion of non-SF residents diagnosed in SF. We defined cases found through death certificate searches, validation studies, and retrospective reviews as "unreported cases" and considered them to be markers of under-reporting.
Results. The incidence of AIDS in HBM appears to level in 1987 and early 1988. We could find no indication that this was due to reporting delays, under-reporting, or a change in the proportion of cases in non-SF residents.

	1985(1)	(2)	1986(1)	(2)	1987(1)	(2)	1988(1)
Total AIDS cases, HBM	410	433	556	667	693	699	671
% Change, from previous 6 mos.	+18	+6	+28	+22	+2	+1	-4
%Reported > 2 mos. after diagnosis	22.2	30.0	26.4	24.2	24.1	25.5	17.4
Unreported cases (%)	12.8	9.0	14.0	10.6	10.9	8.0	6.6
Cases in non-SF residents (%)	7.6	9.9	12.8	9.7	9.8	8.7	9.2

Results were similar when analyzed by date of report.
Conclusion. We observed an apparent decline in the rate of new AIDS cases in HBM in SF. This could not be explained by late reporting, under-reporting, or a decline in non-SF residents coming to SF for diagnosis.

W.A.P.25

ANALYSE DES TENDANCES DES CARACTERISTIQUES SOCIO-DEMOGRAPHIQUES DES CAS DE SIDA RAPPORTES EN FRANCE

Laporte A.; Hubert B.; Marciniak A.; Cluzan S.; Brunet JB.
Direction Générale de la Santé, Paris, France.

Objectif: A partir des caractéristiques socio-démographiques des cas de SIDA, étude de la dynamique de développement de l'épidémie en France.

Méthodes: Analyse des 5527 cas de SIDA diagnostiqués de Janvier 1984 à Décembre 1988, présence des différents groupes de transmission, en fonction du temps et des variables socio-démographiques.

Résultats: Les tendances globales sont: un viellissement de la population des cas de SIDA (diminution de la classe 30-49 ans,augmentation de la classe des plus de 50 ans); une persistance de la diffusion géographique en 3 zones (région parisienne, sud de la France, région Antilles-Guyane); un glissement des catégories professionnelles intellectuelles et commerciales vers les catégories des ouvriers et des sans profession. Les modifications de la part relative des différents groupes de transmission (baisse de celle des homosexuels et augmentation de celle des toxicomanes) par année de diagnostic ainsi que la modification des caractéristiques de ces groupes au cours du temps expliquent les tendances globales.

Conclusion: L'épidémie de SIDA en France est la somme de plusieurs épidémies indépendantes et décalées dans le temps. Certaines modifications des variables démographiques traduisent une augmentation de la proportion des cas à incubation longue.

W.A.P.26

AIDS IN THE DEPARTMENT OF VETERANS AFFAIRS: DEMOGRAPHICS AND EPIDEMIOLOGY

Allen, Robert E.; Mather, S.H.; Peterson, M.R.
AIDS Program Office, Department of Veterans Affairs, Washington, D.C., USA.

Objective. To describe the characteristics of the individual AIDS patients cared for in one of the largest national health care systems in the world, the Department of Veterans Affairs (DVA) of the United States.
Methods. The DVA has collected data on AIDS patients since 1979. The reporting form is identical to those used by the Centers for Disease Control (CDC). From these forms computerized data has been collected to describe the age, sex, ethnic and risk groups for these patients. The results of these analyses will be reported.
Results. At the end of 1988 the DVA had cared for 3,634 AIDS patients in 141 VA medical centers across the USA. This represents approximately 6% of all of the AIDS patients reported in the USA. VA patients are different in risk behavior for the disease in the following way: Intravenous (IV) drug users account for 27% of all of the DVA cases, 7% are both IV drug abusers and homosexual. In other characteristics they are very similar, e.g. 48% are white, 97% are male and they are on the average 41 years of age. In addition, the AIDS epidemic has also been concentrated in epicenters, i.e. 52% of the patients have been cared for in 11 of the VA medical centers. The details of these findings will be further explained at the meeting.
Conclusion. The AIDS epidemic continues to involve an ever increasing number of patients in the USA. The DVA cares for 6% of these cases. These patients differ from the USA reported AIDS patients in risk group percentage. The IV drug users account for 27% of all of the patients cared for since 1979. These data will be presented and discussion encouraged.

Mortalité liée au SIDA
AIDS/HIV Related Mortality

W.A.P.27

IMPACT OF AIDS ON MORTALITY IN SAN FRANCISCO: 1979-1986.

Saunders, LD; Rutherford, George; Lemp, GF; Barnhart, L.
Department of Public Health, San Francisco, California U.S.A.

Objective: To describe the increase in AIDS-related deaths and years of potential life lost before 65 years (YPLL-before age 65) for San Francisco residents between 1979 and 1986.
Methods: Death certificate data for San Francisco residents for 1979-1986 were used to calculate the number of deaths and YPLL-before age 65 for the following six AIDS-related diseases: cytomegalovirus infection (ICD-9 078.5); cryptococcal infection (ICD-9 117.5); *Pneumocystis carinii* pneumonia (ICD-9 136.9); other malignant neoplasms of the skin, site unspecified (ICD-9 173.9); immunodeficiency with predominant T-cell defect (ICD-9 279.1); and immunodeficiency unspecified (ICD-9 279.3).
Results: The number of AIDS-related deaths (both sexes, all ages) increased from 5 (0.1% of all deaths) in 1979 to 534 (6.6%) in 1986. YPLL-before age 65 increased from 123 years in 1979 to 13,276 years in 1986. AIDS-related deaths increased between 1979 and 1986 from 0 to 44 (24.7% of all deaths); 0 to 257 (43.6% of all deaths); 0 to 150 (35.2% of all deaths) in males aged 20-29 years; 30-39 years; and 40-49 years respectively. In 1986 AIDS-related diseases were the third leading cause of deaths and the leading cause of YPLL-before age 65 among San Francisco male residents.
Conclusions: There was a dramatic increase in AIDS-related deaths in San Francisco residents between 1979 and 1986 especially in males aged 20-49 years.

W.A.P.28

HIV-ASSOCIATED MORTALITY IN ENGLAND AND WALES IS GREATER THAN THAT IDENTIFIED BY AIDS SURVEILLANCE

McCormick, Anna.
Office of Population Censuses and Surveys, London WC2B 6JP and PHLS Communicable Disease Surveillance Centre, London, United Kingdom

Objective. To estimate the total number of deaths resulting from HIV infection.
Methods. Ninety-five causes of death were identified as possibly HIV-related. Trends in death rates due to these causes by age, sex, marital status and geographical distribution were identified for 1984-87. Reports to CDSC of HIV infected people who have died but who were not included in the AIDS surveillance programme because they did not meet the WHO definition were analysed. The AIDS surveillance programme was extended in February 1989 to include deaths among HIV-positive people who did not meet the WHO AIDS definition.
Results. Standardised mortality ratios due to HIV-related causes increased for single men aged 15-54 years from 100 in 1984 to 118 in 1987, but there was no similar increase for men of other marital states or for single women. This increase was only partially accounted for by deaths for which AIDS was stated as the cause. Geographical distribution was similar to that of reported AIDS cases. Preliminary results from the extended surveillance programme will be presented.
Conclusion. People in England and Wales are dying as a result of HIV infection without developing AIDS as defined by the WHO. There is a need for surveillance programmes to be extended to include HIV infection severe enough to cause death but not meeting the WHO definition if the true size of the epidemic is to be identified.

W.A.P.29

ESTIMATE OF HIV-RELATED DEATHS IN YOUNG ADULT MEN, UNITED STATES, 1986

Buehler, James; Berkelman R.; Devine O.
Centers for Disease Control, Atlanta, Georgia, USA.

Objective: To estimate the number of HIV-related deaths in 1986 in the U.S. among young adult men.
Methods: Using multiple cause of death records for men 25-44 years of age for the years 1980-1986, we calculated excess deaths in 1986, based on mortality rates in the year with the lowest rates, for selected causes.
Results: In 1980, there were 68 deaths (0.21 deaths/100,000) with any mention of cell-mediated immune deficiency, Kaposi's sarcoma, or *Pneumocystis carinii* pneumonia, and 7,737 such deaths (20.3 deaths/100,000) in 1986 (excess = 7,655). In the absence of these diagnoses, excess deaths occurred in 1986 (following a nadir in rates in 1980-1983) for other conditions in the AIDS definition: infections, 132; non-Hodgkins lymphoma, 158; encephalopathy, 15; and for other conditions that are increasing in association with the HIV epidemic: pneumonia and influenza, 193; pulmonary tuberculosis, 32; septicemia, 136; other infections, 110; other immune deficiency, 135; blood disorders, 57; and non-specific causes, 369. Thus, 7,655 to 9,192 excess deaths may be HIV-related, compared to 7,023 deaths in men 25-44 reported through AIDS surveillance for 1986. Estimated HIV-related deaths may be high if excess deaths are not all due to HIV and low if baseline rates are declining, rather than stable, or if increases in other conditions (e.g., respiratory, drug abuse) are HIV-related.
Conclusion: National surveillance of AIDS cases detected roughly 75-90% of HIV-related deaths in 1986 among men 25-44 years of age.

W.A.P.30

CAUSES OF DEATH IN A LARGE COHORT OF I.V. DRUG USERS (IVDUs) IN MILAN: AN UPDATE

Galli, Massimo; Codini, G.*; Carito, M.*; Cruccu, V.*; Zampini, L.* Ciacci, D.* et al.
Infectious Diseases Clinic and *Drug Abuse services, Milan, Italy.

Objective. To evaluate the variations of causes of death during the last two years in a large cohort of IVDUs recruited in Milan between Nov.80 and Dec.87.
Methods. All the IVDUs attending 4 Hospital Centres were included; 101 subjects deceased before '87; 3604 IVDUs have been followed-up with repeated investigations at registry offices.

Results. (%)	Overdose	AIDS	Liver cirrhosis	Violent death	Other*	Total
1980-1986**	39(39)	11(11)	5 (5)	20 (20)	25(25)	101
1987	18(32)	19(34)	1 (2)	8 (14)	10(18)	57
1988***	20(38)	22(43)	3 (6)	5 (10)	2(2)	52
TOTAL	77(37)	52(25)	9 (4)	33 (16)	37(18)	208

* Only two cases of so-called HIV-related deaths (bacterial pneumonitis) were recorded; **retrospective data; ***Up to Dec.1988 informations were available in 2033. HIV serology was available in 42 AIDS unrelated deaths (88.1% were HIV pos.).

Conclusions. Despite the increasing number of overdose related deaths in Italy during the last two years, in this cohort AIDS is now the first cause of death, so reflecting the large spread of HIV infection among IVDUs in Milan.

W.A.P.31 MORTALITY AMONG 1862 HIV-INFECTED PERSONS IN A GEOGRAPHICALLY DISPERSED U.S. POPULATION: PRELIMINARY RESULTS

Dannenberg,Andrew*; McNeil,J.**; and Brundage J.**.
* National Heart, Lung, and Blood Institute, Bethesda, Maryland, USA,
**Walter Reed Army Institute of Research, Washington, D.C., USA.

Objective:A case-control study is ongoing to assess cause-specific mortality among civilian applicants excluded from military service due to the presence of HIV antibody (cases) or other unrelated medical conditions (controls).
Methods: The 1985-87 files of the National Death Index (NDI) were searched for 1862 cases and 5583 controls (matched 3:1 with cases on age, race, sex, and date and location of screening) identified by US Department of Defense (DOD)screening between 10/85 and 12/87. The cases were 93.6% male, 42.0% white, and 51.3% black. The age range was 17-55 years (median 23.5). Identifiers and HIV status of living applicants were known only by DOD.
Results: Based on a mean follow-up time of 13.5 months (range 0-27), the NDI identified death records for 24 of 1862 cases (12.9/1000) and for 10 of 5583 controls(1.8/1000)($p<.0001$). The death rate for cases (but not controls) was higher ($p<.0001$) than the expected all-cause death rate of 2.6/1000 based on age-,race- and sex-specific 1986 US death rates. Based on death certificates obtained as of 1/30/89 from state vital statistics offices, cases died from AIDS (n=14), pneumonia (2), suicide (2), homicide (1) and drug abuse (2), while controls died from unintentional trauma (4), suicide (1), homicide (1) and drug abuse (1). Annual mortality follow-up of this cohort is planned.
Conclusion: While these preliminary data are insufficient to calculate death rates for non-AIDS causes such as suicide, they suggest an increased all-cause short term risk of death in HIV-infected persons, primarily from AIDS.

W.A.P.33 THE IMPACT OF NON-OPPORTUNISTIC INFECTIONS ON MORTALITY IN A NATIONAL SAMPLE OF AIDS HOSPITALIZATIONS

Barbara J. Turner, M.D.* and Judy K. Ball, Ph.D.**
* Thomas Jefferson Medical College, Philadelphia, PA, USA;
** National Center for Health Services Research, USDHHS, Rockville, MD, USA.

Objective. To determine the importance of non-opportunistic infections (NOI) as a predictor of mortality in hospitalized AIDS patients.
Methods. Discharges with an AIDS or PCP diagnosis were selected from the 1986 Hospital Cost and Utilization Project's (HCUP) national sample of U.S. hospitals. Additional ICD-9-CM diagnosis codes identified pathophysiologic processes and organ system involvement. Logistic regression was used to estimate the relative effects of NOI and opportunistic infections (OI) on in-patient mortality, controlling for the presence of other conditions (wasting syndrome, secondary cancers, hematologic disease, dementia, organ failure), patient demographic characteristics, and region of the U.S.
Results. In 1986, AIDS discharges appeared in 196 of the 400 HCUP hospitals. Of 3230 hospitalizations, 40% had one or more NOI, 39% had PCP, 27% had one or more other OI, and 14% had KS. Overall, in-patient mortality was 18%. OI involving the lung (mostly PCP) or the CNS increased the risk of dying by 106% and 104%, respectively. NOI involving the lung or brain or disseminated NOI increased the risk of dying by 36%, 103%, and 152%. The likelihood of dying in the hospital was generally greater outside of California. Whether the effects of OI and NOI on mortality vary across regions will be examined.
Conclusion. NOI, which are less understood as complications of AIDS, are common and significantly increase in-patient mortality.

W.A.P.35 COMPARISON OF U.S. HIV MORTALITY TRENDS FROM VITAL STATISTICS AND AIDS SURVEILLANCE

Chevarley, Frances*; Kochanek, K.* and Buehler, J.**
*NCHS, CDC, Hyattsville, Maryland, **CID, CDC, Atlanta, Georgia; U.S.A.

Objective. To compare trends in U.S. HIV/AIDS mortality from vital statistics and AIDS surveillance.
Methods. Death certificate information is collected by the States and reported through vital statistics (VS) to the National Center for Health Statistics (NCHS) of the Centers for Disease Control (CDC). The States also report AIDS cases and deaths through AIDS surveillance (AS) to the Center for Infectious Diseases (CID). We compared U.S. HIV mortality from 1983-87 from the VS (multiple cause-of-death data coded to ICD-9 No. 279.1, Deficiency of cell-mediated immunity, for 1983-86; underlying cause-of-death data coded to new U.S. codes *042-*044, implemented in 1987 for HIV infection) to deaths occurring in 1983-87 and reported to date through the AS.
Results. The numbers of deaths reported through VS and AS were 1,141 and 1,405, respectively, in 1983; 10,900 (the most recent final data from VS) and 10,383, in 1986; and 13,130 (provisional, 10% sample of mortality data) and 13,431, in 1987. The ratios of AS to VS deaths decreased from 1.23 in 1983 to 0.95 in 1986 and then increased to 1.02 in 1987. In 1987, the sex distribution (90% male) was the same in both.
Conclusions. The number of HIV/AIDS deaths reported to VS and AS are comparable despite differences in the two systems. VS data depend on the reporting and coding of diagnoses on death certificates; AS depends on reporting for persons who meet the AIDS surveillance definition.

W.A.P.32 AIDS MORTALITY AMONG PUERTO RICAN-BORN RESIDENTS OF NEW YORK CITY: 1981-1987.

Menendez-Bergad, Barbara[1,2]; Drucker,E.[2]; Blum,S.[3]; Perez-Agosto,R.[4]; Parga,J.[4]; Vermund,S.[5]
[1]Lehman College/CUNY; [2]Montefiore Medical Center/Albert Einstein College of Medicine; [3]New York City Department of Health; [4]Centro Latinoamericano de Enfermedades de Transmición Sexual, Puerto Rico; [5]NIAID, Rockville,MD, USA.

Objective. To compare AIDS mortality patterns and rates among Puerto Rican-(PR) born residents of New York City (NYC) to those of Blacks (Blk), whites (Wht), and other Hispanics (Hsp).
Methods. Death certificates for NYC residents with AIDS (n=8187) are analysed by age, sex, race/ethnicity, and place of national origin for the period 1981-1987. This permits differentiation of individuals born in PR from Blk, Wht, and other Hsp. 1980 U.S. Census provides the denominator for cumulative age-adjusted and age-specific AIDS mortality rates. Secular trends for 1981-1987 were examined for AIDS proportional mortality.
Results. Cumulative age-adjusted AIDS mortality rates (per 100,000 pop.) are highest among PR-born males*(362) compared to Blk (267), Wht (182), and Hsp (217). For PR-born females, the age-adjusted rate (59) is highest compared to Blk (56), Wht (14)* and Hsp (25)*. Age-specific rates are highest for PR-born males in all age groups, and in females for ages 35-44.* Secular trends indicate that AIDS proportional mortality from 1983 to 1987 (among minorities) increased most dramatically for PR-born (846%) compared to Blk (656%) and Hsp (682%).*[p<.05]
Conclusion. The disproportionate impact of AIDS on the mortality experience of PR-born New Yorkers suggests high rates of HIV infection in this group and continued risk for the Puerto Rican community in NYC and PR.

W.A.P.34 STABILIZATION OF AIDS MORTALITY IN NON-DRUG USING MEN IN NEW YORK CITY (NYC)

Stoneburner Rand, Stevens C*, Chiasson M, Morrison J*, Ewing E, Singh T, et al. The New York City Department of Health and The New York Blood Center*, New York, New York,U.S.A.

Objective: To assess the course of the AIDS epidemic in New York City homosexual men by analyzing mortality trends from 1980-88.
Methods: Mortality from AIDS and all other causes in men 20-54 not known to be IV drug users (IVDU) was analyzed using the NYC Vital Records. Mortality was also determined in a cohort of 8,331 homosexual males enrolled in a NYC hepatitis B serosurvey in 1978-79.
Results: From 1980-88, 9.3% (6,294/67,535) of deaths in non-IVDU white and non-white (black and hispanic) men were attributed to AIDS. From 6/83 to 12/85, the average AIDS mortality per half-year for whites increased 43%, while from 12/85 to 12/88, the increase was only 5.6%. During the same two time periods AIDS deaths in non-whites increased 44% and 14%. No similar trends were noted in IVDU or women. In the homosexual male cohort, 69% (436/620) of deaths from 1980-88 were attributed to AIDS. The average annual increase in total deaths was 47% for 1983-86, and 1% for 1986-88. The proportion of AIDS deaths increased from 32% (6/15) in 1982 to 78% (65/83) in 1985 where it remained essentially unchanged through 1988.
Conclusion: Stabilization of AIDS mortality in non-IVDU males 20-54, and in the homosexual male cohort suggests a plateau in the epidemic of AIDS in NYC homosexual men. The contribution of outmigration to this stabilization will be examined in the cohort. Behavioral change may be one explanation for the occurrence of this phenomenon before the widespread use of AZT.

Transmission homosexuelle
Homosexual Transmission

W.A.P.36 RISKFACTORS FOR TRANSMISSION AND IMPACT OF KNOWLEDGE OF HIV-AB SEROCONVERSION ON SEXUAL BEHAVIOR AMONG HOMOSEXUAL MEN

Van Griensven, Godfried JP*; Kuiken, C*; De Vroome, EMM**; Coutinho, RA*.
*Municipal Health Service Amsterdam,**State University Utrecht,The Netherlands

Objective. Study of riskfactors for transmission and impact of knowledge of HIVab seroconversion on subsequent sexual behavior among homosexual men.
Methods. Between Oct. 1984 and May 1985 512 HIVab- homosexual men were entered in a cohort study in Amsterdam. Subjects are seen every 3 mo. for medical history, physical examination and the collection of bloodsamples and psychosocial and behavioral data. During follow-up until Jan. 1989 59 men seroconverted for HIVab, 34 in 1985, 16 in 1986, 3 in 1987 and 6 in 1988. For each HIVab seroconversion 2 HIVab- controls were selected at random and matched in time, taking the seroconversion date as reference.
Results. Compared to controls seroconversions show a peak in anogenital receptive activity during 12-6 mo. prior seroconversion. Seroconversions increase from a mean of 1 to 6 partners while controls remain stable around 1. Changes in sexual behavior during 6-36 mo. after knowledge of seroconversion appear to be relative because sexual activity returns to the initial level before the peak-period. Anogenital insertive intercourse is the only activity which goes below the initial level. In multivariate analysis anogenital receptive intercourse was the only significant riskfactor for seroconversion. No evidence was found that orogenital contact or a history of (ulcerating) STD's were riskfactors.
Conclusion. Data suggest peak-periods in sexual behavior 12-6 mo. prior seroconversion. Sexual behavior after seroconversion should therefore be studied by comparing it with the initial level of sexual activity before the peak-period. Anogenital receptive intercourse remains the primary riskfactor.

W.A.P.37

RETROSPECTIVE STUDY OF FACTORS RESPONSIBLE FOR HIV TRANSMISSION IN MALE HOMOSEXUALS

Anastasia,Roumeliotou;Kallinikos,G.;Kotsianopoulou,M.;Nestoridou,A.;Trichopoulou,E. and Papaevangelou,G.
National Center for AIDS,Athens School of Hygiene,Athens,Greece.

Objective.To study factors affecting the prevalence of HIV infection in male homosexuals.
Methods.Male homosexuals self-selected for counselling and HIV screening at the National Center for AIDS were asked to complete a detailed questionnaire. The sample included 90 anti-HIV positive and 100 anti-HIV negative male homosexuals.All of them were also screened for serological evidence of HBV infection,syphilis and history of past gonnorhea.
Results.Table 1 showes epidemiological characteristics and the prevalence of STD in the examined anti-HIV positive and negative male homosexuals.

Characteristics/Disease	Anti-HIV(+)n:90	Anti-HIV(-)n:100
Median age(years)	28	28
Number of sexual contacts / month	5	5
Use of condom (%) last year	28.9	76.0
I.V. drug use (%)	6.7	2.0
Active and passive sexual behaviour (%)	73.3	56.0
Hepatitis B	73.3	58.0
Syphilis	33.3	15.0
Gonnorhea	55.0	40.0

Conclusions.There is a close correlation between HIV infection and other sexually transmitted diseasesUnprotected sex and both passive and active sexual behaviour are mainly responsible for HIV infection in male homosexuals.

W.A.P.38

RISK FACTORS FOR HIV INFECTION AMONG MALE PROSTITUTES IN ATLANTA

Kirk Elifson, J. Boles, M. Sweat, Georgia State University, Atlanta
W. Darrow, Centers For Disease Control, Atlanta, GA, U.S.A.

Objectives To assess HIV seroprevalence among male prostitutes and to identify risk factors for HIV infection.
Method Between July 1988 and January 1989, 147 active male street prostitutes were recruited in two locations in Atlanta. Standardized interviews were conducted and blood samples collected in the respondents' natural setting. Interviews focused on sexual history, drug-use history, social networks, and health issues. Blood specimens were tested for HIV antibodies by EIA and Western Blot, and for syphilis by RPR, MHA-Tp, and FTA-Abs. Risk factors associated with HIV antibody seropositivity were identified using step-wise logistic regression analysis.
Results Of the 147 hustlers 28% were seropositive for HIV. Residing in a predominantly black area, rather than race, was the most significant predictor of HIV infection. Intermittent condom use (use between 33% and 66% of time), was significantly associated with HIV infection while infrequent and frequent condom use were not significant. In our most parsimonious model predictors for HIV infection were:

Risk Factor	% of Sample	% HIV Pos.	Odds	95% C.I.
Black Area of Residence	11.6	61.8	2.31	1.51-3.11
Receptive Anal Sex	24.5	47.2	2.25	1.66-2.84
Syphilis Seromarker	22.4	55.3	2.03	1.51-2.54
Intermittent Condom Use	38.8	38.7	2.01	1.46-2.55
Hustling >= 10 years	27.9	46.1	1.98	1.33-2.63
Acquaintance W/ P.W.A.	52.4	35.8	1.76	1.24-2.28

Age (median 23 years), race (48% black), IV-drug use (46.3%), and self-reported sexual orientation (31% homosexual, 40% heterosexual, and 27% bisexual), were not significant.
Conclusions: Preliminary results indicate that male prostitutes represent a possible conduit of HIV infection to both the heterosexual and homosexual populations. Additionally, residence in a predominantly black area and receptive anal intercourse are better predictors of HIV infection than race and sexual orientation.

W.A.P.39

RELATIONSHIP OF STD HISTORY TO HIV SEROPOSITIVITY IN A COHORT OF HOMOSEXUAL MEN IN DALLAS, TEXAS.

Haley, Charles E.; Anderson P, Freeman A, Petty A.
Dallas County Health Department, Dallas, Texas, USA.

Objective: To determine the relationship between STD history and anti-HIV.
Methods: Between 6/87 and 12/88, 644 homosexual or bisexual men volunteered to return every six months for HIV testing. All answered questions about previous episodes of syphilis, gonorrhea, genital warts, and hepatitis.
Methods: 320 (50%) of the men had a history of either syphilis, gonorrhea or warts; 153 (19%) had a history of hepatitis.

History of a Sexually Transmitted Disease:

	Syphilis	Gonorrhea	Warts	any 3	Hep B	Non A hep
N	104	238	131	320	65	110
HIV+	49(47%)	95(40%)	51(39%)	120(38%)	30(46%)	46(42%)
RR	1.9	1.9	1.5	2.0	1.8	1.6
95% CL	1.5-2.5	1.5-2.4	1.2-2.0	1.5-2.6	1.3-2.4	1.3-2.2

When stratified by the number of partners in the year before learning of AIDS, the RR for HIV infection in those with a history of syphilis, gc, or warts was 1.8 (95% CL: 1.4-2.4) and for those with a history of non A hepatitis was 1.4 (95% CL:1.1-1.8). HIV infections were related to the number of episodes of gonorrhea (x^2trend=32; p<.001) and to the number of partners (x^2trend=8; p<.01).
Conclusions: HIV infections may be related to history of STD due to the facilitation of HIV transmission, but the similar relationship with non-A hepatitis suggests that HIV infections and STDs may be independant events associated with a common mode of transmission.

W.A.P.40

HIV-1 DISCORDANT COUPLES IN THE BALTIMORE MACS STUDY

Palenicek John G, Fox R, Odaka N, Armenian H, Harris J, Hardy W, Taylor E, et al. The Johns Hopkins School of Hygiene and Public Health, Baltimore, MD, USA.

Objective To determine infection status, sexual practices and coinfections of HIV-1 serologically discordant couples in the Baltimore MACS.
Methods Thirty-four self-identified serologically HIV-1 discordant, 5 HIV-1 seropositive and 17 seronegative concordant couples had detailed sexual histories taken and blood drawn for laboratory tests.

Results	Concordant Seropositive	Discordant Sero+	Discordant Sero-	Concordant Seronegative
Number of persons	10	34	34	34
X CD4	607	585	1183	1180
X CD4/CD8 ratio	0.6	0.6	1.9	2.1
HIV-1 culture positive	6/10	28/33	2/33	1/34
HIV-1 DNA detected (PCR)	1/1	7/7	0/7	1/4
Anal insertive sex:				
- with primary partner	8/10	27/34	29/34	30/34
- never using condom	2/8	13/27	9/29	20/30
Anal receptive sex:				
- with primary partner	10/10	29/34	28/34	30/34
- never using condom	3/10	11/29	12/28	17/30

Conclusion Sexually active HIV-1 discordant couples exist without evidence of viral transmission. The presence of 3 virus positive seronegative persons in this high risk population requires further investigation.

W.A.P.41

FAILURE TO CONFIRM HERPES SIMPLEX VIRUS TYPE 2 (HSV-2) INFECTION AS A RISK FACTOR FOR HIV-1 SEROCONVERSION AMONG HOMOSEXUAL MEN.

Kingsley, Lawrence; Armstrong, J.; Rahman, A.; Ho, M. and Rinaldo, C.
University of Pittsburgh, Graduate School of Public Health, Pittsburgh, Pennsylvania, USA.

Objective. To determine if prior infection with HSV-2 is associated with HIV-1 seroconversion in homosexual men.
Methods. Western blot confirmed HIV-1 seroconverters (n=49) were matched with non-HIV-1 seroconverters (n=49) for the number of partners with whom anal receptive intercourse was performed and the visit of HIV-1 seroconversion. HSV-2 Ab testing was performed on blind-coded sera utilizing immunoaffinity-purified gG-2 in an immunoblot assay.
Results. At the visit of HIV-1 seroconversion, the same prevalence of HSV-2 infection was observed for both HIV-1 seroconverters and non-seroconverters (23/49, 47%). Matched pairs analysis failed to detect any association between HSV-2 infection and HIV-1 seroconversion (odds ratio = 1.0). Self-reported rates of genital and ano-rectal sores were very low (≤4%), as well as physical exam findings suggestive of HSV infection (≤2%).
Conclusion. No evidence was found in this study to support the hypothesis that prior/current infection with HSV-2 is a risk factor for HIV-1 seroconversion among homosexual men. A suggested explanation is that anal intercourse is the major risk factor for both HIV-1 and HSV-2 ano-genital infection, HSV-2 infection among homosexual men may be only a marker of, not a risk factor for, acquisition of HIV-1 infection. Due to both cultural and biologic differences in heterosexual transmission of HIV-1, these findings should not be generalized to other risk groups.

W.A.P.42

SEROEPIDEMIOLOGIC STUDY OF HIV INFECTION AMONG HOMOSEXUAL MEN ATTENDING A MEDICAL PRACTICE IN MONTREAL

Remis, Robert*; Najjar, M.*; Pass, C.*; and Paradis G.*.
*Bureau régional des maladies infectieuses, Montreal,Quebec,Canada.

Objective. To determine the prevalence of HIV infection and characterize sexual behaviour, socio-demographic factors and knowledge about AIDS among homosexual men.

Methods. A cross-sectional study of HIV infection, comprising anti-HIV testing and a self-administered questionnaire including information on lifetime sexual history, current sexual behaviour, knowledge about AIDS and lifetime history of STD's.

Results. Over a 2-month period, 84 men entered the study. The study cohort included subjects 18 to 60 years of age who were mostly French-speaking (69%) and Montreal island residents (96%). The median number of lifetime sexual male partners was: 110 (total) and 7 (with whom they had receptive anal intercourse). Subjects aged 30 to 39 years had the most number of partners per year of sexual activity. Anti-HIV was found in 21 (25%) of subjects. There was no significant difference in HIV status or any other characteristic between men who visited the clinic for HIV-related reasons and those who consulted for non-HIV-related reasons. Anal receptive intercourse, younger age at first homosexual experience, use of sex toys, poppers and drugs, history of STD's including hepatitis B were strongly correlated with a seropositive result. During the one month period prior to the study, unprotected anal insertive intercourse was reported by 3 (14.3%) of 21 seropositive men; unprotected anal receptive intercourse was reported by 12 (19.1%) of 63 seronegative men. Seventy-two percent of subjects who had prior knowledge of a positive HIV status scored above the overall median score on questions relating to knowledge about AIDS, compared to 47% of subjects who knew they were negative and none of those who had no previous knowledge of their HIV status (p<0.002).

Conclusion. This study provides evidence that an important proportion of homosexual men in Montreal have still not adopted safe sex techniques and lack adequate knowledge about AIDS. Use of drugs might be an important factor in HIV transmission.

W.A.P.43 RISK FACTORS IN HOMOSEXUAL TRANSMISSION OF HIV

Ennio Ricchi*, P.Costigliola*, M.Borderi*, M.Bentale *, M.C.Re**, F.Chiodo*
*Istituto Malattie Infettive - **Istituto di Microbiologia; Universita' di Bologna, Bologna, ITALY.

Objective. To evaluate the risk factors linked to HIV infection in a cohort of Italian homo-bisexual men enrolled in 1985-1988, and to look for their modifications during that period.
Methods. We have studied 856 homo-bisexual men (i.v. drug addicts excluded) from Northern Italy that refer of one's own free will to HIV screening program. All answered an epidemiological interview about sexual habits (# partners/year, "safe-sex", sexual intercourse behavior) and underwent HIV test (performed by ELISA, WB confirmed). A cohort of 375 subjects which were HIV AB -ve at first examination have periodically repeated the interview and HIV test every six months for a follow up period of 12-36 months.
Results. HIV Ab prevalence during Jan 1985-Dec 1987 is reported in TABLE I.

TABLE I	#	HIV Ab +ve	%
1985	256	33	12.9
1986	129	17	13.1
1987	211	10	4.7
1988	268	9	3.4

Seventeen from the follow-up group (375 subjects) seroconverted during 1985-1988, with annual rate of 2.3%. During 1987-1988 the interviewed homo-bisexuals have reported a more drastic reduction of promiscuity rather than t he observance of "safe sex".
Conclusion. The major behavior change seen in Italian homo-bisexual community is mainly the reduction of promiscuity, which can explain the slow diffusion of HIV in this group.

W.A.P.44 EPIDEMIOLOGICAL, IMMUNOLOGICAL AND BEHAVIOURAL PARAMETERS IN A COHORT OF HOMOSEXUAL MEN; SEQUENTIAL CHANGES OVER SIX YEARS.

Mulhall, Brian P.*,Carter,L. *, Frazer,I.H.**
*AIDS Service, Royal Melbourne Hospital, Melbourne, Australia; ** Princess Alexandra Hospital, Brisbane, Australia.

Objective: To determine rates of seroconversion and predictors of immune deficiency and their relation to sexual life-style.
Methods: In 1983 a cohort of 100 asymptomatic homosexual men was recruited for a prospective study at a major teaching hospital. HIV seroconversion and immune function assessments were performed at six monthly intervals. In addition, all members were counselled and information on sexual life-style was elicited by questionnaire.
Results: The prevalence of antibody to HIV rose from 22% in 1983 to 31% in 1985. There have been no further seroconversions. Five patients have developed group IVc disease, and five AIDS.
Modelling analysis demonstrates the predictive value of repeated measurements in the seropositive group, for CD4 T cells (t=2.3, p=0.02) and immunoglobulin concentrations (t=3.36, p=0.002). There has been a highly significant decrease in the number of sexual partners and the number of reported STD's (p<0.01). There has also been a significant fall in the frequency of unsafe sex, though not to zero, and an increase in the use of condoms. This applies to receptive and active anal intercourse, but not to oral intercourse.
Conclusions: 1. The spread of HIV into and within this group has been halted.
2. Although there are clear group trends; for a single individual, serial and not point-measurements are required to predict immunodeficiency.
3. The combination of motivation and counselling has resulted in a reduction of practices perceived to be unsafe.

W.A.P.45 THE DEVELOPMENT OF ACQUIRED IMMUNODEFICIENCY SYNDROME (AIDS) AMONG TWO COHORTS OF SEXUALLY TRANSMITTED (STD) PATIENTS WITH DIFFERENT VENEREAL DISEASE HISTORIES.

Wayne X. Shandera
Dallas County Health Department. Current affiliation: Dept. of Medicine, Ben Taub Hospital, Baylor College of Medicine, Houston, TX, USA.

OBJECTIVE: To assess the risk of acquiring HIV infection among 2 cohorts of homosexual men treated for syphilis and other venereal infections in Dallas County, Texas.

METHODS: Two groups of homosexual male patients with venereal exposures were analyzed by a retrospective chart review. The first included 302 individuals with a history of early (primary or secondary) syphilis during 1986; the second, 114 controls (matched by first initial of last name) with a history of culture-proven gonococcal urethritis but without any history of syphilis. The rate of AIDS in the 2 groups was assessed by reviewing a registry of local AIDS cases that had been diagnosed by mid-1988.

RESULTS: The number of AIDS cases among the two groups was similar: 14 (4.6%) among the patients with a history of early syphilis during 1986 and 6 (5.3%) among the matched control patients with a history of gonorrhea during 1986 (χ^2 = 0.252, p>0.25).

CONCLUSION: Among American homosexual men, a relationship between a history of early syphilis and an increased rate of AIDS cannot be conclusively established 2 years after the episode of early syphilis and suggests that a history of syphilis does not serve as conclusively as a risk factor for HIV infection and AIDS among American homosexual men as it does among AIDS patients belonging to other at-risk populations such as those treated and reported from central Africa.

W.A.P.46 RECENT HIV SEROCONVERTERS (SC) IN A SAN FRANCISCO COHORT OF HOMOSEXUAL/BISEXUAL MEN: RISK FACTORS FOR NEW INFECTION.

Lifson, Alan R.*; O'Malley,PM.*; Hessol,NA.*; Doll LS.**; Cannon,L.*; Rutherford,GW.*. *Department of Public Health, San Francisco, CA; **Centers for Disease Control, Atlanta, GA, USA.

Objectives: To describe homosexual/bisexual men (HBM) who recently seroconverted to HIV antibody (Ab) and behavioral risk factors for these SC.
Methods: Since 1983, follow-up studies have been conducted on a cohort of HBM recruited from 1978-1980 for hepatitis B studies. Eleven HBM whose estimated year of seroconversion was during 1986 (6) or 1987 (5) were compared to 288 persons who remained seronegative (SN).
Results: During an interview period of 12-33 months (median=19) preceding the estimated date of seroconversion, SC reported a median of 20 sexual partners (range=1-425); 3 SC reported only 1-2 partners. 8/11 SC reported engaging in receptive anal intercourse without a condom, 2/11 SC reported only insertive anal intercourse without a condom, and 1 SC denied anal intercourse and reported only receptive and insertive oral-genital contact with multiple partners. Prior to the date of seroconversion, 7 SC had been told that they were HIV-Ab negative based on a previous sample. Compared to SN, SC had a greater number of both steady and nonsteady sexual partners; SC were also more likely to have engaged in both receptive and insertive anal intercourse without a condom. SC and SN did not differ with respect to age, race, education, sexual contact with a female, or use of IV drugs.
Conclusion: A small number of HBM continue to seroconvert to HIV, primarily in association with unprotected receptive or insertive anal intercourse. Although multiple partners are also associated with an increased risk of seroconversion, some SC reported only 1 or 2 partners.

Transmission verticale
Vertical Transmission

W.A.P.47 MATERNAL FACTORS AND NEONATAL CHARACTERISTICS ASSOCIATED WITH HIV INFECTION IN INFANTS OF SEROPOSITIVE WOMEN.

Nair, Prasanna; Johnson, J.; Hines, S.; Alger, L and Seiden, S.
Department of Pediatrics, University of Maryland School of Medicine, Baltimore, Maryland, U.S.A.

Objective. To correlate maternal and neonatal characteristics with perinatal tranmission of HIV.
Methods. In a prospective study of perinatal transmission infants born to seropositive women were assayed for anti-HIV IgG, IgM, and HIV antigen at 2, 4, 6, 9 and 12 months of age. Data on 35 infants born to HIV positive women, 15 of whom show evidence of being infected, are presented.
Results. All mothers of infected infants and 90% of mothers of non-infected infants had history of I\V drug use. There was no significant difference in age, education, type of family, marital status, parity or age at first pregnancy. The incidence of STD infections during pregnancy was higher in mothers of infected babies (40% vs 25%) and their participation in methadone treatment programs was significantly lower (37% vs 55%). Birth weights, gestational ages and perinatal problems were similar in both groups except for neonatal abstinence syndrome due mostly to methadone withdrawal which was higher in the non-infected group (55% vs 27%).
Conclusion. In this group of infants transmission of HIV appears to be associated with maternal lifestyle characteristics.

W.A.P.48 RISK FACTOR(RF) IN SYMPTOMATIC HIV SEROPOSITIVE (SP) CHILDREN IN THE SAN JUAN CITY HOSPITAL (SJCH), PUERTO RICO

Eleanor Jimenez, M.T. Carrer, L. Lopez, I. Perez, C. Reyes.
Department of Pediatrics, Pediatric Hematology Section, San Juan City Hospital Medical Center, San Juan, Puerto Rico.

The SJCH is the only public hosp. which serves the medically indigents (aprox. 225,000 pts./yr.) residents of the SJ metro. area (total pop. 425,749, 1985) many of them with a serious public health probelm of IVDU.
Objective: To determine the RF and mode of transmission of HIV infection in symptomatic children from 0-13 years of age at SJCH.
Method: Data from the medical records of the Ped. HIV Clinic was analysed, SP pts. were identified form 1985 to 1988 (ELISA, WB.).
Results: 95 SP pts. were identified. P-0=39 (41%), P-1=4 (4%), P-2=52 (55%). Of the 52 symptomatic pts., 48 (92.3%) were perinatally infected (PI) and 4 (7.7%) blood acquired. The RF of parents in the PI children were:

IVDU....................45 (93.5%)—
19 (42%) father
19 (42%) mother
4 (9%) both parents
3 (7%) previous husband
Several Sex Partners...2 (4.2%)
Unknown................1 (2.0%)

Heterosexual infection in mothers was 50% (n=24) and ↑ in the last 3 yrs (44% 82-84 vs 58% 85-88), 92% of them (n=22) was related to IVDU in sex partners.
Conclusion: Perinatal infection was found to be the predominant mode of transmission (92.3%) in the symptomatic pts. at SJCH. IVDU was the most important RF in parents and directly related to this mode of transmission. The mayority of the SP mothers were infected by a IVDU sexual partner. Both perinatal infection and IVDU are higher in SJ metro. area than in the rest of P.R.

W.A.P.49

PROSPECTIVE STUDY OF THE VERTICAL TRANSMISSION OF HIV.

Jack Levy, S.Sprecher, J.Duchateau, N. Clumeck, J.Hinane, C. Zissis et al. Collaborative Group for the Study of Pediatrics AIDS, Belgium.

Objective : To evaluate prospectively the vertical transmission of HIV.
Methods : Infants born to HIV infected mothers are followed up clinically since birth and tested at 3 months intervals for HIV antibodies (Ab) by a quantitative anti P24 assay as well as for the presence of virus in cultures of lymphocytes and proviral DNA by PCR.
Results : Since 1985, 32 children have been included.Twenty two were born from parents originating from Central Africa. Mean follow up is 12.5 months (range 1-36). To date 1 child has AIDS, 4 have mildly enlarged lymph nodes and the rest of the cohort is asymptomatic. Fifteen children have become seronegative at ages ranging from 4 to 18 months. Half-life of anti P24 Ab in these children was comparable (30 days) and the age at which they became seronegative was dependent on the amount of anti P24 Ab present at birth. Two children, (1 with AIDS and 1 asymptomatic) have significant immunologic impairment and anti P24 Ab that do not decrease over time, suggesting active production. Seventy eight HIV cultures have been performed in 22 children : 3 were positive (2/4 in the child with AIDS and 1/6 in an asymptomatic child). Detection of proviral DNA by PCR using primers in the GAG and LTR genes has been attempted in 15 infants. Two different samples have been tested in 9 children (5 positive, 2 negative and 2 discordant results) and 1 sample in 6 (5 positive and 1 negative).
Conclusion : 1) quantitative follow up of anti P24 Ab correlates with clinical and immunologic outcome; 2) proviral DNA is detectable by PCR in seronegative asymptomatic children. The significance of this finding remains to be elucidated.

W.A.P.50

PERINATAL TRANSMISSION OF HIV-1 IN LUSAKA, ZAMBIA.

Hira,Subhash*;Bhat,G.*;Kamanga,J.*;Mwale,C.*;Luo,N.*;Perine, P.**; et al.
*University Teaching Hospital, Lusaka, Zambia;**Uniformed Services University of Health Sciences, Bethesda, MD, U.S.A.

Objectives.1.To determine perinatal transmission rate; 2.To determine morbidity and mortality of HIV-1 infection in children.
Methods. A prospective study was conducted on 1954 women in labour at University Teaching Hospital in Lusaka, Zambia. 227 (11.6%) of women were Western blot confirmed seropositive for HIV-1. Excluding pregnancy wastages and those lost to followup, 105 sets of seropositive mothers and their children and 40 sets of seronegative mothers and their children (control) were followed monthly for 2 years.
Results. Of 227 seropositive women, 49 (21.6%) had PGL or ARC. Low birth weight was significantly encountered among infants born to seropositive women. During followup, 22 children died under age of 8 months; 14 with clinical AIDS. Remaining 83 children were retested at 8 months of age and 23 (27.7%) were seropositive. Thereafter, fewer children became seronegative and few others became seropositive. By 18 months of age, another 4 died with AIDS, 5 were terminally ill, 22 had ARC and 2 were asymptomatic seropositive. Thus, including those 14 who had died under 8 months of age with clinical AIDS, the perinatal transmission rate was 47/105 (44.8%). The mortality rate among infected children was 18/47 (38.3%) in first 2 years of life. Significant clinical features among infected children were failure to thrive (72.4%), anemia (20.7%), hepatosplenomegaly (20.7%), adenopathy and candidiasis (6.9%).
Conclusions.1.Perinatal transmission occured in 44.8%; 93% developed illness.

W.A.P.51

PERINATALLY ACQUIRED HIV INFECTION AND THE RISK OF VERTICAL TRANSMISSION IN RIO DE JANEIRO - Brazil.

Signorini, Dario José Hart; Rubini, N.P.M.; Rocco, R.; Eyer-Silva, W.A.; Sion, F.S.; Morais de Sá, C.A.
Gaffrée & Guinle University Hospital - University of Rio de Janeiro (UNI-RIO) - Brazil.

Objective: To study the natural history of perinatally acquired HIV infection and evaluate the risk of vertical transmission.
Methods: The study comprised 10 HIV infected pregnant women (positive both at ELISA and IF) who were admitted to our Hospital from June 1986 to December 1988. Clinical classification was based on CDC criteria. Children were examined shortly after delivery and at 3-monthly intervals.
Results: Mothers were 20 to 41 years of age (28,8 ± 7,4), 6 (60%) were white and 4 (40%) non-white. Risk factors were as follows: 6 (60%) IVDU, 2 (20%) had a history of blood transfusion and 2 (20%) had bisexual partners. Eight (80%) were classified as group II, 1 (10%) as group III and 1 (10%) as group IV. One mother died during gestation and one delivered a stillborn. From the 8 children born, 5 (62,5%) were male and 3 (37,5%) were female. Mean ± SD birthweight was 2826,6 ± 725,8 g (1600 to 3580g). Mean gestation was 38,9 ± 4,4 weeks (31 to 42 weeks). Six (75%) had positive anti-HIV antibody tests and 2 (25%) were negative at birth. All children were well clinically at delivery. We observed congenital abnormalities in the fetus from the mother who died during gestation. At the end of study, 2 (25%) were still negative after 15 months, 4 (50%) were positive but had less than 15 months of follow-up, 1 (12,5%) had asymptomatic infection and 1 (12,5%) developed AIDS. The 2 non-infected children were born by vaginal delivery and were breast-fed.
Conclusions: Our data suggest that: a) Perinatal HIV transmission does not appear to affect weightbirth and gestational age. b) Mode of delivery and breastfeeding do not appear to affect the rate of vertical transmission. c) We could not yet estimate the rate of vertical transmission, since only 4(50%) children have reached 15 months of age.

W.A.P.52

HIV-ISOLATIONS IN PREGNANT WOMEN AND THEIR OFFSPRING

Agneta Ehrnst*, Lindgren S**, Bohlin A-B**, Ottenblad C**, Czajkowski J*, Sönnerborg A*, Blomberg J, Nemeth A
* The Central Microbiological Laboratory of the Stockholm County Council, and ** Huddinge Hospital, Stockholm Sweden, *** The University of Lund, Lund, Sweden.

Objective: To study the relationship between HIV-viremia in pregnant HIV-positive women and HIV-transmission to the child or foetus.
Methods: From HIV seropositive women, heparinized blood was drawn at the time of abortion for HIV-isolation from plasma and peripheral blood mononuclear cells (PBMC). The aborted foetus was subjected to HIV-isolation. In seropositive women who continued their pregnancy HIV-isolation was performed similarly at gestation weeks 12,20,36, after partus, and six months later. The children were tested by isolation during the first week of life, at 6,12,18 and 24 months of age. Whereas all children were tested around birth few have been followed the whole period of 2 years.
Results:

No of pair of		HIV-isolation in the woman from plasma	PBMC	either	or in the child/foetus any site
women and child:	7	5/7	5/7	6/7	0/7[1]
women and foetus:	7	3/6	4/7	5/7	1/7[2]
Total:	14	8/13	9/14	11/14	1/14

1) HIV was isolated at 6 months of age in plasma in 1 child. 2) HIV was isolated from brain.

Conclusion : Despite the high rate of viremia during pregnancy there was no virus recovered from the neonates and from only one foetus.

Progression de l'infection à la maladie
Progression from Infection to Disease

W.A.P.53

FOLLOW UP OF HIV-INFECTED HOMOSEXUALS WITH LYMPHADENOPATHY SYNDROME (LAS).

T HARRER+, K MESSING*, E MEYER+, U BIENZLE*, JR KALDEN+
+Medizinische Klinik III of the University Erlangen-Nuernberg, 8520 Erlangen, FRG *Landesinstitut für Tropenmedizin,D-1-Berlin, Federal Republic of Germany

OBJECTIVE: To look for the incidence of developement of AIDS in a cohort of homosexual men with LAS.
METHODS: Between 1982 and 1984 26 homosexual men were examined clinically and immunologically, inclusive a lymphnode biopsy. Epidemiological factors, clinical symptoms and immunological parameters were correlated to the clinical outcome.
RESULTS: The 26 homosexuals were prospectively observed over a period of 58 months (median, range 53-69 months). None of the patients was treated with HIV-specific therapies. 16 (61.5 % developed full blown AIDS within a median period of 41 months (23-63 months). 12 of them died 50 months (median, range 29-67 months) after the first examination. 10 patients showed no symptoms of AIDS after a median observation time of 57 months (54-63 months). A decreased proportion of CD4-cells and a lower CD4/CD8-ratio in the lymphnode suspensions at the first examination in patients with disease progression were the only parameters which correlated with the development of AIDS.
CONCLUSION: The incidence of AIDS is rising continuously with increasing observation time.

W.A.P.54

RISK OF AIDS IN PATIENTS WITH HERPES ZOSTER, PGL OR 'OTHER' FEATURES OF ARC.

Hira,Subhash*;Tembo,G.*;Wadhawan,D.*;Kamanga,J.*;Macuacua,R.*; Perine,P.** *University Teaching Hospital, Lusaka, Zambia; **Uniformed Services University of Health Sciences, Bethesda, MD, U.S.A.

Objective.To study the risk of developing AIDS in patients presenting with herpes zoster, PGL, or those with 'other' features of ARC.
Methods.Three cohorts of patients at University Teaching Hospital in Lusaka were followed for periods varying from 6 to 40 months: I. 212 with herpes zoster;II. 200 with PGL; III. 168 with 'other' features of ARC like diarrhoea, fever, weight loss, cough etc. All patients were confirmed seropositive for HIV-1 using Immunofluorescent assay. Using patient-months of observation as the denominator, rates of progression to AIDS among cohorts were extrapolated.
Results.Of 212 herpes zoster patients, 62 (29.7%) progressed to AIDS. By comparison, 19 (9.3%) of 200 PGL patients and 17 (10.1%) of 168 patients with 'other' features of ARC also progressed to AIDS. Age, sex, number of sexual partners, past STDs etc were not significantly different among the cohorts. The rate of progression to AIDS per 12 patient months were:

	Months of Observation			
	1-10	11-20	21-30	31-40
Herpes zoster	0.49	0.24	0.21	0.19
PGL	0.18	0.06	0.07	0.09
'Other' features	0.15	0.15	0.25	——

Conclusion. The fast rate of progression of patients with herpes zoster to AIDS suggests that it is an indicator of poor prognosis.

W.A.P.55 INCIDENCE OF AIDS IN SPANISH HIV INFECTED PATIENTS

José M Gatell, Podzamczer D, Clotet B, Ocaña I, Estany C, Miro JM and BARCELONA AIDS STUDY GROUP. Hospitals Clinic, Bellvitge, Terrasa, Germans Trias, and Vall d'Hebron, Barcelona, Spain.

OBJECTIVE. To describe the incidence of AIDS (CDC criteria of August 1987) among persons infected with the HIV in Barcelona (Spain) where drug addicts are the most frequent risk group and tuberculosis the most common initial manifestation of AIDS.
METHODS. A total of 2100 people who were at high risk for AIDS, had enrolled in cohort studies of homosexual men, parenteral drug users and hemophiliacs before december 1986. A total of 922 were either HIV seropositive at enrollment or seroconverted subsequently, and could be followed-up. 646 (70%) of the 922 were parenteral drug addicts.
RESULTS. The AIDS developed in 95 (10.3 %) during a median follow-up period of 30 months (range 12 to 72 months). Using actuarial survival calculations, the estimated 6-year cumulative incidence of AIDS among all HIV seropositive subjects was 23 % (range 14% to 44%; 95% confidence interval). Among the homosexuals, drug addicts and hemophiliacs cohorts the incidence at 6 years was 15%, 15% and 32% respectively (P>0.05). Comparing the survival functions the risk of developing AIDS was significantly greater among those presenting with, or developing during the follow-up period, a disease included in the CDC stages IV A and IV C-2 (P<0.0001).
Conclusion. The risk of AIDS development after 6 years of HIV infection was 23% and the progression rate among drug addicts was not significantly different than the progression rate of male homosexuals or hemophiliacs.

W.A.P.56 NATURAL HISTORY OF HIV INFECTION IN WOMEN OF CHILD BEARING AGE IN UGANDA.

Dr. E. A Mworozi, Dr. S. Kiguli - Makerere University, P.O. Box 7072, KAMPALA, Uganda.

Objective: To determine the morbidity and mortality rates associated with HIV infection among women of child bearing age.

Methodology: 87 HIV Seropositive mothers were recruited from an antenatal clinic at Nsambya Hospital in Kampala City. These were prospectively followed up at monthly intervals for 0 - 35 months.

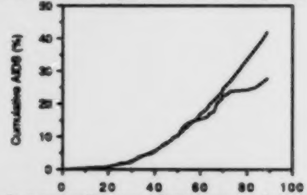
Results: During the follow-up period most of the women had delivered twice, 4 mothers had died, 3 of whom had enteropathic AIDS (SLIM), 1 had neuropsychiatric manifestations, 41 are still being followed-up out 4 of whom currently have ARC/AIDS was 5.9% per year. The rate of progression in this cohort of women who delivered children and lactated is comperable to what has been found for the general population in other studies elsewhere.

Conclusion: From this study pregnancy and lactation did not accelerate the rate of progression to ARC/AIDS.

W.A.P.57 DEFLECTION OF AN AIDS PROGRESSION CURVE IN A GAY COHORT

Schechter, Martin T*; Craib KJP*; Le TN*; Willoughby B*, Montaner JSG*.
*The Vancouver Lymphadenopathy-AIDS Study, Vancouver, BC, Canada.

To study patterns of AIDS progression, we fit a Weibull distribution to the first 60 months of AIDS progression in a cohort of 351 HIV+ men [233 seroprevalent (SP); 118 seroincident (SI)]. We first estimated 18 months of lead time for SP based on laboratory parameters and by comparing with SI. The model was then fit (lambda=0.009; β=2.75), extended to 88 months, and graphed with the actual progression as below.
The model (upper curve) gives rise to projections that agree with published studies. The actual progression (lower curve) deflected away from the model after 60 months. The observed Kaplan-Meier progression at 88 months was only 28% (whereas 42% was predicted by the model).



AIDS progression in a seropositive gay cohort appears to have deflected from a Weibull distribution. We speculate this may be an early effect of the wider use of zidovudine. Drug effects will have to be accounted for in natural history studies and in epidemiologic projections.

W.A.P.58 PROGRESSION TO AIDS IN COHORTS OF SEROPREVALENT AND SEROINCIDENT GAY MEN: RESULTS AT 6 YEARS

Craib, Kevin JP*; Schechter MT*; McLeod WA*; Weaver MS*; Willoughby B*; Douglas B*; Sestak P*; Le TN*; Maynard M*; O'Shaughnessy MV**; et al.
*The Vancouver Lymphadenopathy-AIDS Study, St. Paul's Hospital and the University of British Columbia, Vancouver, BC, Canada. ** Federal Centre for AIDS, Ottawa, Ontario, Canada

Objective. To determine the rate of progression to AIDS in a cohort of seropositive gay men stratified by those who were seropositive at entry and those who seroconverted under study.
Methods. We identified all seropositive subjects in our prospective study who completed at least 2 visits during the period 11/82 to 12/88. This group was divided into seropositives at entry (seroprevalent: SP) and those who seroconverted under observation (seroincident: SI). AIDS was diagnosed in this cohort according to CDC criteria. Methods of survival analysis were used to calculate progression rates to AIDS. Kaplan-Meier estimates of cumulative progression were calculated as were actuarial annual attacks rates, namely the conditional probability of AIDS among those AIDS-free at the beginning of the year. Cox regression was used to model predictors.
Results. A total of 351 seropositive subjects were included in the analysis (233 SP, 118 SI). The median lengths of observation while seropositive were 62.0 mos (range=1-72) for SP and 49.5 mos (range=10-69) for SI. A total of 69 cases of AIDS were observed (59 SP; 10 SI). Product limit estimates of cumulative progression were 28.7% (±3.5) for SP at 72 months and 11.1% (±3.4) for SI at 60 months. The annual AIDS attack rates for the first 6 years in SP were 2.1%, 3.9%, 7.8%, 5.3%, 9.0% and 5.2% respectively; and 0.0%, 1.0%, 3.0%, 6.0% and 2.1% for the first 5 years in SI respectively. CD4 counts, C1q binding, and IgA levels independently predicted AIDS.
Conclusion. Progression by 5 years in SI, a true inception cohort, is estimated to be about 11%. SP appears to have a mean lead time infection period of about 18 months. The drop in annual attack rate seen in the final year in both SP and SI could be due to reporting delay but we speculate it is more likely due to recent wider use of zidovudine.

W.A.P.59 PROGRESSION OF HIV DISEASE AMONG INTRAVENOUS DRUG ABUSERS (IVDA): A THREE-YEAR PROSPECTIVE STUDY.

Tirelli Umberto, Saracchini S., Diodato S., Serraino D., Martelli P., Vaccher E. AIDS and Related Syndromes Study Group. Centro di Riferimento Oncologico, Aviano, Italy.

Objective. To determine the progression rate of HIV disease among IVDA. **Methods** Between 1984 and 1987, a prospective evaluation of 319 IVDA was made. 103/319 (32%) were HIV seropositive (Elisa with Western Blot confirmation) and 68/319 (21%) were affected by PGL, 31 (10%) of whom without systemic symptoms (group III of CDC classification), 27 (8%) and 10 (3%) with systemic symptoms classified IV A and IV E respectively. Only 159/319 (50%) were followed regularly for a median duration of 14 months (range 1-38), and are the object of this evaluation. **Results.** At first clinical examination 87 were HIV negative and 72 HIV positive, and of the latter group none had full-blown AIDS, 40 were symptomatic and 32 asymptomatic. Progression of HIV disease is documented in the Table

	HIV- (N°87)	HIV+ (N°72)
Seroconversion	5/87 (6%)	-
Disease progression: asymptomatic → symptomatic	0	11/32 (34%)
symptoms worsening:	0	15/40 (38%)
AIDS	0	4/40 (10%)
O.I. (C2)	0	8/40 (20%)
symptoms	0	3/40 (8%)

Conclusion. After a median follow-up of 14 months, 5/87 (6%) of previously HIV negative IVDA seroconverted, and 4/72 (6%) of HIV-seropositive developed full-blown AIDS. In addition, despite educational efforts, a large number (60%) of HIV positive IVDA still exchange syringes and needles and only a few (17%) use condoms.

W.A.P.60 DEVENIR DE SUJETS INFECTES PAR LE V.I.H. : PREMIERS RESULTATS D'UNE SURVEILLANCE HOSPITALIERE.

Dabis, François*; Commenges, D.*; Chêne, G.**; Pellegrin, J.L.**; Schmitt, A.** et le Groupe d'Epidémiologie Clinique du Sida en Aquitaine (GECSA)**.
*Département d'Informatique Médicale, Université de Bordeaux II, France.
** Centre Hospitalier Régional Universitaire (CHRU), Bordeaux, France.

Objectif. Un système de surveillance épidémiologique a été mis en place au CHRU de Bordeaux. Il permet d'étudier l'évolution clinique des sujets infectés par le V.I.H.
Méthodes. Les services hospitaliers participants incluent les patients séropositifs depuis 1985. A chaque consultation, les données sont recueillies sur un questionnaire standardisé, puis sont rendues anonymes et informatisées. La classification utilisée est celle des Centers for Disease Control. Les probabilités cumulées d'atteindre le stade IV ou le stade SIDA sont calculées par la méthode de Kaplan-Meier.
Résultats. Au 10 octobre 1988, 648 adultes séropositifs ont été inclus. Parmi ceux-ci, 253 patients classés stade II ou III à l'inclusion ont été revus au moins une fois et leurs données sont analysées. 75% sont des hommes. Le groupe à risque élevé le plus représenté est celui des homo/bisexuels (42,5%) chez les 190 hommes et celui des toxicomanes IV (53,3%) chez les 63 femmes. La proportion de transfusés est de 17,2% dans les deux sexes (incluant 8% d'hémophiles). Les sujets de ce groupe ne diffèrent pas des autres patients inclus dans la cohorte en termes d'âge, de sexe et de groupe à risque. Leur probabilité cumulée d'atteindre le stade IV est de 11,1% après 12 mois (IC à 95% : 6,2%-16%) et de 18,7% après deux ans de suivi (IC à 95% : 10,5%-29,2%). Leur probabilité cumulée d'atteindre le stade SIDA est de 7,5% après 12 mois (IC à 95% : 2,7%-10,1%) et de 12% après deux ans de suivi (IC à 95% : 3,4%-20,6%). Les sujets ayant atteint le stade IV (n=30) sont des toxicomanes IV dans 56% des cas et des transfusés dans 24% des cas.
Conclusion. Les données actuellement recueillies sur le devenir des sujets infectés par le VIH sont comparables avec celles de la littérature. La mise en place de ce système de surveillance épidémiologique de l'infection par le V.I.H semble importante pour évaluer le temps de passage des sujets asymptomatiques vers le stade IV et le stade SIDA. De plus, ce système permet de déterminer les sujets éligibles pour définir et étudier de nouvelles stratégies thérapeutiques.

W.A.P.61 RISK ESTIMATES OF AIDS IN HEMOPHILIACS

Joyce F. Killinger*, PS Rosenberg#, JJ Goedert#, LM Aledort**, K Vaidya##, CM Kessler***, MH Gail#, et al. *RTI, Research Triangle Park NC 27709 USA; # NCI, Bethesda MD 20892; **Mt Sinai Medical Ctr, New York 10029;## Cardeza Hemophilia Ctr, Philadelphia PA 19107;*** George Washington Univ Hospital, Washington DC 20037 for the NCI Hemophilia AIDS Study Group.

Objective. To estimate the proportion of HIV-infected adult and juvenile hemophiliacs who will eventually develop AIDS and to evaluate the uncertainties in these estimates.
Methods. A mixed Weibull survival model was fit to AIDS incidence data from 328 hemophiliacs whose dates of HIV seroconversion were known, including 33 AIDS cases among 174 adults (age at seroconversion >21) and 11 AIDS cases among 154 children. No intermediate markers such as T4 counts were analyzed. The AIDS-free survival distribution was given by F(t)= p * exp(-λ*t**γ) + 1-p. The proportion p who will ever develop AIDS was estimated from its profile likelihood together with confidence intervals.
Results. For adults, the profile likelihood was very flat, and indeed one could not strongly reject the possibility that p=1. However, our best estimate of p was .34 with 95% confidence interval (.22,1.0). Results for children were similarly uncertain, with an estimate of p=.13 with 95% confidence interval (.07,1.0). For all 328 hemophiliacs combined, our best estimate of was p=.24, with a 95% confidence interval (.16,.66).
Conclusion. Our data yield very imprecise estimates of the proportions who will ever develop AIDS and certainly do not demonstrate that all HIV-infected hemophiliacs will develop clinical disease. Indeed, our estimates of p are much lower than those reported for studies of homosexual men.

W.A.P.63 FOLLOW-UP OF A COHORT OF EX IVDAs RESIDENT IN THERAPEUTICAL COMMUNITIES IN ITALY.

Marasca Giuseppe*, Fiume A.**, Marchitelli C.**, Masini V.**, Prestileo T.**, Zampieri A.* et al.
*Istituto Superiore di Sanità, Rome, Italy, **Comunità Incontro, Terni, Italy.

Objectives. To describe the natural history of HIV infection in ex IVDAs not longer exposed to intravenous drugs and to assess cofactors in the progression of the infection.

Methods. During 1988 all 2,428 residents in the 75 therapeutical communities (TC) cohordinated by Comunità Incontro were clinically evaluated and tested for HIV. Risk factors for HIV infection were assessed by face to face interviews using a structured questionnaire. For those who were HIV seropositives a prospective follow-up was initiated while clinical and serological retrospective data were actively searched.

Results. All 2428 residents were tested for HIV and 1392 (57%) were found repeatedly positives. Complete retrospective data are available for 710 (52.3) HIV +ve subjects, median follow-up 12.5 months (range 3-41 months). No AIDS cases were admitted at the TC and no AIDS cases occurred in the cohort during 1988. 508 (71.5%) subjects were asymptomatic at first visit and still such at last recall. The remaining 202 (28.5%) subjects were symptomatic either with persistent generalized lymphadenopathy or with constitutional disease or both. During the follow-up period 98 subjects (48.5% of the symptomatic) showed no signs of progression or regression, 58 subjects (28.7%) showed clear signs of improvement, while the remaining 46 subjects (22.8%) showed clinical regression. A complete analysis will be presented at the conference.

Conclusion. Former intra venous drug users infected with HIV infection, living in a semi-closed conditions do not seem to show a faster progression to AIDS than other groups. However it is still to early to say whether HIV +ve residents in TCs have a better prognosis than others.

W.A.P.65 NATURAL HISTORY OF HIV-1 INFECTION FOLLOWING PREGNANCY

Datta, Pratibha*; Embree, J.E**,+; Braddick, M***; Kreiss, J +,*; Ndinya-Achola, J*; Plummer, F.A*,**.
*University of Nairobi, Kenya,** University of Manitoba, Winnipeg, Canada, ***Middlesex Hospital, U.K, + University of Washington, Seattle, U.S.A.

Objective: To study the influence of pregnancy on HIV-1 disease progression.
Method: Women attending a maternity hospital in Nairobi, Kenya were screened for HIV-1 Ab at delivery. HIV+women were enrolled in a prospective cohort study and followed for HIV related illness.
Result: One hundred and twenty eight HIV+ women were enrolled and followed for a mean of 10(range 1-28)months. At enrollment, 115(90%) women were asymptomatic (AS)and 13(10%)had systemic disease(SD):6 chronic pruritic rash (R),1 hairy leucoplakia & R, 5 Herpes zoster(Z),1 Kaposi sarcoma(KS). Using survival analysis, the cummulative proportion(CP)of AS women developing SD or dying was 21%:3 died of HIV related illness at a mean of 4.7(range 0.5-9) months, 5 had Z at 19.6(range 12-28)months,3 developed chronic oral and/or vaginal candidiasis at 16.5(range 12-24)months, and 1 developed R at 6 months. Four initally AS mothers delivered second infants and remained asymptomatic at 25.5(range 24-27)months. Of the 13 women with SD at delivery a CP of 51% had progression of HIV disease or died:2 died of AIDS (1 KS, 1 wasting illness at 7 months each), and 2 developed additional manifestations of HIV (R with oral & vaginal candidiasis at 7 months, oral candidiasis at 1 month).
Conclusion: In this cohort of women, by survival analysis one fifth of initially asymptomatic women progressed to HIV related illness/death within 2 years after delivery, and one half of the women with systemic disease at delivery had further progression of HIV disease or died within 9 months.

W.A.P.62 Enhanced prediction of AIDS in HIV sero-positive asymptomatic men: Relative Value of 8 Cellular and Serologic Markers Singly and in Combination.

J. Fahey, JMG Taylor, R Detels, B Hofmann, R Melmed, P Nishanian, JV Giorgi
UCLA Schools of Medicine and Public Health, Los Angeles, California, U.S.A.

Objective: To evaluate 8 cellular and serologic markers singly and in combination for their ability to predict the occurrence of AIDS within 4 years.
Methods: CD4 T cell number, percent, and CD4/CD8 ratio were determined by flow cytometry. Serum neopterin, beta-2-microglobulin (B2M) soluble IL-2 receptor (sIL-2R), IgA, and p24 HIV antigen were determined by serologic tests. The relative hazard from abnormal levels of these were calculated using the proportional hazards model. A random sample of 395 individuals were chosen from 813 seropositive individuals, participating in the Los Angeles Center of the Multicenter AIDS Cohort Study and were followed for 4 years or until the diagnosis of AIDS.
Results: CD4/CD8 ratio and CD4 T cell percent were reduced and/or serum neopterin levels were elevated in more than half of the subjects (outside the normal 10th-90th percentile range). Reduced CD4 T cells (number, percent or ratio) was the best single predictor of AIDS. Neopterin and B2M are similar in their predictor ability and slightly less good than CD4. Neopterin appeared to be slightly better than B2M. IgA and sIL-2R both have predictive ability but not as strong as neopterin or B2M. Neopterin, B2M, sIL-2R, IgA, and p24 antigen all have statistical significance independent of CD4, i.e., they add to CD4 predictive ability. Neopterin appears to add the most. In a stepwise procedure the following variables were chosen in order: CD4/CD8 ratio; neopterin, IgA, sIL-2R, antigen.
Conclusion: These studies indicate that measurements of multiple parameters reflecting different facets of HIV infection add to predictive value regarding the occurrence of AIDS. The most important measurements were CD4 T cell levels (ratio, percent, or number) and serum neopterin or B2M. Soluble IL-2R, IgA and p24 antigen, can be useful but do not add appreciably if the other measurements are made.

W.A.P.64 AIDS YEARLY INCIDENCE IN 1984 HIV SEROPREVALENT COHORT: NO DEFINITE TREND 1985-1988

Visscher, Barbara R.; Jacobson, L.; Detels, R.; Dudley, J.; English, P.; Chmiel, J.; Ho, M.; and Polonicek, J.G. Multicenter AIDS Cohort Study, Los Angeles, California, U.S.A.

Objective: To observe temporal trends in the incidence of AIDS in a cohort of seropositive men.
Methods: Approximately 1870 homosexual men seropositive on 1984 enrollment in the Multicenter AIDS Cohort Study (MACS) have been followed for progression to AIDS. Excluding the first semester which was incomplete, and the last semester for which reporting is not yet finished, the semi-annual incidence rates per 100 person semesters of follow-up were calculated for each center and for the MACS as a whole.
Results: Incidence of AIDS in Seropositives by Semester:

Semester	AIDS cases	Person semesters (PS) at risk	AIDS inc. per 100 ps	AIDS Incidence by Center Balt	Chi	LA	Pitts
1/85-6/85	28	1651	1.7	0.9	1.5	2.3	1.1
7/85-12/85	60	1607	3.7	3.8	3.9	3.8	3.2
1/86-6/86	64	1500	4.3	4.3	5.1	4.3	2.3
7/86-12/86	45	1391	3.2	2.1	3.8	3.9	1.9
1/87-6/87	73	1273	5.7	4.8	7.4	5.5	5.2
7/87-12/87	37	1201	3.1	5.2	1.9	2.8	2.8

Conclusion: The AIDS incidence in seropositive men differs by center, but there is no clear increasing trend over this period of time.

W.A.P.66 THE PROGNOSIS OF ASYMPTOMATIC HIV INFECTION: THE UNITED STATES ARMY THREE YEAR EXPERIENCE.

Redfield, Robert; Brundage, J.; Oster, C.; Tramont, E.; Burke, D., and the US Army Retrovirus Research Group,
Department of Retroviral Research, Walter Reed Army Institute of Research, Rockville, MD, U.S.A.

Objective. To describe the natural history of early HIV infection and delineate prognostic parameters. Methods. Early diagnosis of HIV infection is the standard of medical practice in the US Army. All HIV seropositive individuals are clinically evaluated and staged per the Walter Reed Staging Classification. Revaluation occurs at 3-12 month intervals. Results. To date 1950 individuals have been enrolled including over 1200 with follow up visits greater than 1 year.

Initial Stage	N	FOLLOW UP STAGE WR1	WR2	WR3	WR4	WR5	WR6	DEATH
WR1	447	48%	28%	12%	5%	5%	1%	0.2%
WR2	479		66%	19%	6%	8%	1%	0.6%
WR3	186			65%	15%	16%	3%	3%
WR4	53				57%	28%	11%	4%
WR5	49					49%	29%	22%

Progression of asymptomatic HIV infection to clinical immunodeficiency correlated with CD4 count, DTH skin reactivity, and initial WR stage of infection and duration of follow up. Life table analysis for each variable independently and in combination will be presented.
Conclusion. All asymptomatic HIV seropositive adults can be clinically classified by the Walter Reed Staging Classification providing important prognostic information. Wide scale clinical application is feasible as demonstrated in the US Army Health Care System.

W.A.P.67

ESTIMATION OF MATURITY OF HIV-1 INFECTION IN SUBGROUPS OF SEROPREVALENT COHORT OF HOMOSEXUAL MEN. Muñoz, Alvaro; Carey V; Saah A; Chmiel J; Detels R; Kingsley L; Van Raden,M. for the Multicenter AIDS Cohort Study (MACS), Bethesda, MD, USA.

Objective. To compare infection times of a prevalent seropositive cohort of homosexual men according to geographic location, ethnicity and age. Methods. By matching values of hematological variables of seroprevalent individuals at entry into the MACS with those observed in follow-up of seroconverters, we estimated the length of time each seroprevalent had been infected prior to entry. Bootstrap methods incorporating uncertainty of the imputation procedure were used to compare maturities of infection in MACS subcohorts. Results. The subcohort of 1744 seroprevalent homosexual men in MACS was enrolled between 4/84 and 4/85. Hematological variables were provided by 1717 (98.5%). Percentages of the seroprevalent cohort whom we estimate seroconverted by the beginning of 1979,'80,'81,'82,'83,'84, and '85 were 0.3%, 1.1%, 4.0%, 15.6%, 40.9%, 79.3% and 99.9% respectively. The median times from seroconversion to entry for those enrolled in Pittsburgh (N=186), Baltimore (N=331), Chicago (N=443) and Los Angeles (N=757) were 14.4, 15.1, 15.4 and 15.8 months respectively. Non-hispanic black (N=77) seroprevalent participants had a median time since seroconversion of 16.4 months compared to 15.3 months for non-hispanic whites (N=1484). Mean age of the cohort was 32.9 years (SD=6.6). Older age was associated with longer infection times prior to entry. None of the comparisons was statistically significant. Conclusion. We estimate that half of the seroprevalent cohort of the MACS enrolled in mid-1984 was infected before the beginning of 1983. The data suggest that infection with HIV-1 occurred at approximately the same calendar time in demographic subgroups of this sample of seroprevalent homosexual men.

W.A.P.68

AIDS-FREE TIME AFTER HIV-1 SEROCONVERSION IN HOMOSEXUAL MEN ACCORDING TO DEMOGRAPHIC SUBGROUPS. Muñoz, Alvaro; Bass S; Saah A; Chmiel J; Taylor J; Kingsley L; for the Multicenter AIDS Cohort Study (MACS), Bethesda, MD, USA.

Objective. To compare the AIDS-free time after seroconversion in homosexual men according to geographic location, ethnicity and age. Methods. We combined statistical information provided by 1637 (330 AIDS) seroprevalent (SP) homosexual men and 267 (17 AIDS) seroconverters (SC). Unknown times since seroconversion of the SP cohort were estimated using hematological variables provided at baseline (Muñoz, et al.,IV IAC). An extension of Cox regression to incorporate truncation was used to estimate relative hazards. Precision was assessed by bootstrap methods. Results. The 1637 SP individuals were enrolled in mid-1984 and we estimated a median infection time of 15 months prior to entry. The 267 SC had a median follow-up time of 32 months. Relative hazards (RH) and 95% confidence intervals (CI) were:

	N	AIDS	RH	95% CI
Pittsburgh	232	34 (14.7%)	1.00	
Baltimore	378	72 (19.0%)	1.04	(0.69-1.59)
Chicago	489	91 (18.6%)	1.16	(0.73-1.71)
Los Angeles	805	150 (18.6%)	1.04	(0.75-1.51)
Non-hispanic black	89	12 (13.5%)	1.00	
Non-hispanic white	1651	308 (18.7%)	1.16	(0.65-2.49)

Older age was significantly ($p<0.05$) associated with shorter AIDS-free time (RH for 10 years increment=1.22,95%CI=1.02-1.42). Conclusion. In this sample of homosexual men, AIDS developed at the same time for different geographic locations and different ethnic groups. Older individuals have shorter AIDS-free time after seroconversion. Due to the small sample of blacks, ethnic differences cannot be ruled out.

W.A.P.69

STATISTICAL MODELS FOR ASSESSING FEEDBACK: AN ANALYSIS OF BEHAVIOR AND IMMUNE FUNCTION IN THE MULTICENTER AIDS COHORT STUDY.

Zeger, Scott L.; Liang KY; Park L; Fox R; Kingsley L; Taylor J; Chmiel J; Kaslow R, for the Multicenter AIDS Cohort Study (MACS), Bethesda, MD, USA.

Objective. In a feedback (FB) system, an outcome variable affects a second which subsequently affects the first. Statistical methods are developed for FB systems and for assessment of whether immune function (%CD4 deficit), and behavioral variables, in particular unprotected anal receptive intercourse (UARI), are part of such mechanisms.
Methods. Linear regression models developed for longitudinal data describe the deficit in %CD4 for HIV-1 seropositive men relative to seronegatives from the same MACS-site and time period as a function of sexual practices, and covariates such as drug use and other infections. The probability of UARI in a 6-month interval is then modelled using a logistic regression for longitudinal data as a function of %CD4 deficit at the beginning of the interval, previous sexual practices and other covariates. Constraints on the coefficients in these 2 simultaneous regression models are derived.
Results. Men who had more UARI, more sexual partners and used recreational drugs in the previous year had relatively fewer CD4 cells. The rate of UARI decreased dramatically during the follow-up. Controlling for time dependence and for other covariates, UARI during an interval was more likely among men with relatively higher CD4 cells at the beginning of the interval.
Conclusion. These data are consistent with the existence of a FB mechanism in which unprotected anal receptive intercourse during an interval is associated with an increased loss of %CD4 cells at the end of the interval which in turn is associated with a lower frequency of unprotected anal receptive intercourse in the next interval.

W.A.P.70

SURVIVAL AND TIME OF PROGRESSION TO AIDS AMONG PATIENTS AT GAFFRÉE & GUINLE UNIVERSITY HOSPITAL, RIO DE JANEIRO, BRAZIL.

Sion, Fernando Samuel*; Eyer-Silva, W.*; Rachid de Lacerda, M.C.*; Morais de Sá, C.A.*; Castilho, E.A.**; Guimarães, M.D.C.***

* Gaffrée & Guinle University Hospital, University of Rio de Janeiro (UNI-RIO) - Brazil
** CIS-FIOCRUZ - Brazil
*** UFMG and FIOCRUZ - Brazil

Objective: To estimate the time required for progression to AIDS among adult patients with Persistent Generalized Lymphadenopathy (PGL) and survival following the diagnosis of AIDS.
Methods: We evaluated 97 PGL patients seen at Gaffrée & Guinle University Hospital, Rio de Janeiro, Brazil, from Dec 1, 1983 to Dec 31, 1988 for survival following AIDS diagnosis and time of progression to AIDS following PGL. Survival parameters were estimated using product-limit function.
Results: 97 PGL patients with mean age 32,28 (± 7,99), comprising 87 (89,7%) males and 10 (10,3%) females, 80 (82,5%) whites and 17 (17,5%) blacks, 81 (83,5%) homo/bisexual men, 8 (8,2%) female partners of bisexual men and 8 (8,3%) others/undetermined. 30,0% of the patients progressed to AIDS mean time of 43.9 ± 2.02 months while the median time was 57 months. Among the 27 patients with AIDS 40,7% had died by Dec 1988 with mean survival time of 13.5 ± 1.5 months and median survival of 19 months, 40% of the patients survived for more than 35 months. In addition, 88 asymptomatic HIV infected patients, with unknown time of infection, were regularly followed and time of progression to AIDS was assessed. Nine (10,2%) patients progressed to AIDS with mean time of 22.1 ± 0.7 months, as diagnosed at the first visit.
Conclusion: Our data support the high proportion of progression to AIDS after initial symptoms and the high letality as observed in other studies.

W.A.P.71

NATURAL HISTORY OF HIV INFECTION IN A COHORT OF INTRAVENOUS DRUG USERS (IVDUs): A FIVE YEARS PROSPECTIVE STUDY.

Muga Roberto,Tor J,[illegible],Ginestà C,Rey-Joly C,Foz M
Service of Internal Medicine.Hospital de Badalona "Germans Trias i Pujol",Universitat Autònoma de Barcelona,Barcelona,Spain.

Objective: To determine seroconversion rates, clinical progression and AIDS incidence in a longitudinal study of HIV infection among intravenous drug users (IVDUs).
Methods:From June 83 to June 88, 442 non-AIDS IVDUs were enrolled in a prospective study that included: HIV antibodies (Ab) tests (EIA) and phisycal exams at baseline evaluation, and followed-up every 6 months.
Results: 133/442 (30%)of IVDUs enrolled were seronegatives (SN) and 309/442 (70%)were seropositives (SP); 178/442 (40.2%) patiens were followed for a mean of 18 months and rest were controlled just one.
Among SN, 38 out of 133 (28.5%) were followed-up ; 10 out of 38 (26.3%) had seroconverted after keeping seronegatives for a mean of 15.8 months. 28 out of 38 cases still SN after a mean of 18 months (p=NS).
Clinical status: At entry, 87/309 (28.1%) patiens were asymptomatic (Group II); 151/309 (48.8%) had PGL (Group III) and 71/309 (22.9%) had ARC (Group IV).
145 out of 309 HIV infected (non-AIDS) had been followed-up for a mean of 17 months; 37/136 (27.2%) showed clinical progression of the disease.
Conclusion: Data suggest a high prevalence of HIV infection, substantial rates of seroconversion and clinical progression. The small number of cases who developed full-blown AIDS could be due, among others, to the fact that this infection is of later appearance in our area.

W.A.P.72

PROBLEM-ORIENTED DATA COLLECTION FOR NATURAL HISTORY STUDIES OF HIV-INFECTED PATIENTS

Stitt, Frank W.*; Dickinson, G.**; Kilman, H.G.**; and LaPerriere, G.**.
*University of Miami, Miami, FL; **VA Medical Center, Miami, FL, USA.

Objective. To develop a method for data abstracting, indexing, & classification of clinical and laboratory manifestations from HIV+ patients. Methods: An integrated, dictionary-driven database has been used to register patients, record admission episodes, 'problems' (which include diagnoses), and problem management on patients referred to the Special Immunology Service, VAMC. Problems are indexed using a comprehensive preferred terminology of 5,400 problems, 7200 procedures and 2,500 symptoms and signs. The problem dictionary is cross-referenced with ICD-9-CM for statistical aggregation, and with SNOMed for indexed retrieval on lower level medical concepts. The database is being used to measure the incidence of clinical manifestations over time and to compare them among risk groups. Statistical clustering methods and graphical display methods for viewing coded data are used to analyse and review the clinical manifestations. Patients are classified and staged using algorithms written in statistical programming languages.
Results: To date, 781 patients have been registered. There have been 1,505 admissions with 3345 problem mentions entered. Tabular and graphical displays demonstrate the methods used.
Conclusion: Problem-oriented medical record databases provide a useful alternative to pre-coded form-based checklists for thorough data acquisition and study of HIV-related clinical manifestations.

W.A.P.73

PROGRESSION OF HIV1 DISEASE IN A POPULATION OF SEROPOSITIVE NAVY AND MARINE CORPS PERSONNEL.

Mayers, Douglas.*, Wilson, D.B.*, Wagner, K.F.**.
* National Naval Med. Center, Bethesda, Maryland and ** Henry M. Jackson Foundation, Rockville,MD U.S.A.

Objective. To determine the rate of HIV1 disease progression (prog) in screened seropositive active duty military personnel.
Methods. We have evaluated 517 HIV1 seropositive personnel with serial evaluations. 159 patients were evaluated at 9 to 15 months (1 year) and 67 patients were seen at 21 to 27 months (2 years). Each evaluation was point staged using the Walter Reed classification based on the clinical data for that visit alone.
Results.

	1 YEAR			2 YEARS		
Initial Stage	N	%Prog	% AIDS	N	%Prog	% AIDS
1 - 2	115	22	0	45	42	2
3 - 4	32	18	0	18	39	11
5	5	60	60	4	75	75
All Stages	159	20	2	67	43	9

Conclusions. There was 43% progression in Walter Reed stage and 9% progression to AIDS at 2 years in this population sample. There was an average T4 cell decline of 50±176 cells per year with a normal distribution about the mean. For patients with T4 cell counts between 600 and 200 cells the rate of decline was essentialy linear ranging from 60 to 82 T4 cells lost per year in each T4 interval examined.

W.A.P.74

PROSPECTIVE MULTICENTER COHORTSTUDY IN HOMOSEXUAL MEN IN FRG. A 4-YEAR FOLLOW UP: EPIDEMIOLOGICAL RESULTS.

Schwartländer, Bernhard, for the Study Group.
AIDS-Zentrum im Bundesgesundheitsamt, Berlin,
Federal Republic of Germany

Objective: To evaluate the natural course of HIV-infection.

Methods: In 1984 a prospective multicenter cohortstudy was started in FRG. A total of 771 homosexual men were recruited in 7 centers in metropolitan areas. At time of enrollment 432 (56 %) men were positive to HIV-antibodies, 25 of these had full blown AIDS. Cohortmembers are examined twice a year.

Results (Selection): 75 of the HIV-infected homosexual men developed AIDS during time of observation. The incidence of AIDS was a constant 5% per year. For only 2 cases with AIDS the time of infection is known. To gain a better figure of the course of HIV-infection and the time of latency, we calculated the probability, that CD4-cell counts fall below certain limits. On the basis of these calculations a model was developed which allows the prognosis of the development of HIV-disease in the cohort: 12 - 13 years after HIV-infection 80% of the infected individuals will have less than 300 CD4+ cells/ul.

Discussion: The beginning (time of infection) and the end (AIDS/death) of the course of HIV-infection is not known for the vast majority of HIV-infected individuals. A stochastic model on the basis of data from our cohort may help to gain a better understanding of the time course of HIV-infecton.

W.A.P.75

NATURAL HISTORY OF HIV INFECTION AMONG IV DRUG ABUSERS IN BASQUE COUNTRY

Arrizabalaga, J.; Iribarren, J.A.; Garde, C.; Cilla, G.; Etxaniz, P.; Zubizarreta, G., Hospital Nuestra Señora de Aránzazu. San Sebastian. Spain.

Objective: To describe the natural history of HIV infection among IVDAs.

Methods: Of 350 IVDAs screened in 1985 for VIH, 227 (65%) were seropositive. Of these, 100 entered a follow-up cohort. After an initial evaluation, they were screened every 8 months. We present the preliminary data obtained at 32 months follow-up.

Results: In the initial study 85% were asymptomatic, 8% only presented some analytic alteration (anemia and/or lymphopenia and/or thrombocytopenia) and 7% had lymphadenopathic syndrome (LAS). After 32 months we evaluated 76 of them: 22 (28.9%) are asymptomatic; 27 (35.5%) are in group II with some analytic alteration; 11 (14.5%) are in group III, 9 (11.8%) of them with analytic alteration; and 16 are in group IV: 10 (13.2%) of them meeting AIDS criteria (group IV-C-1), 5 (6.6%) in group IV-C-2 and 1 (1.3%) in group IV-A. In 71% of patients the disease have progressed.
Considering the group of IVDAs who initially presented clinical or analytic alterations, 50% (6/12) developed AIDS and in 91.66% (11/12) the disease progressed. Of the patients originally asymptomatic, 6.25% (4/64) have developed AIDS and in 67.2% (43/64) the disease have progressed. We discuss the behavior of the clinical and analytic findings of these patients over the course of four screens.

Conclusion: We conclude by indicating that 13.2% of the group have developed AIDS and that the course of the disease is greatly influenced by the patient's initial clinic and analytic status.

W.A.P.76

DEGREE OF HIV-RELATED CNS INVOLVEMENT AND LONG-TERM SURVIVAL: PRELIMINARY RESULTS

Kenny, F.T., MacFadden, D.K. Dept. Medicine, University of Toronto, Toronto Western Hospital, Toronto, Ontario Canada.

Twenty-three homosexual men at various stages of HIV-related illness and 6 seronegative men have been entered into a longitudinal study of HIV-induced CNS dysfunction. All subjects were given an initial (baseline) set of clinical, immunologic, CT and neuropsychological assessments and then re-assessed at 6 month intervals. Results indicate that ARC patients (IVa&b) are most cognitively impaired at the time of admission while AIDS patients (IV:C-1) show a wide diversity of impairment; however, there appears to be an inverse relationship between the extent of impairment at baseline and survival among AIDS patients (high impairment/short survival). Furthermore results indicate that CNS involvement precedes the development of AIDS (presentation with PCP) in many cases and that ARC patients have considerable CNS involvement despite the absence of opportunistic infection. In the majority of AIDS patients there is a progression of CNS involvement across assessments but 20% of patients may survive for over 2.5 years without significant CNS impairment; long-term survival may depend heavily on this relationship.

W.A.P.77

IMMUNOLOGIC AND VIROLOGIC DETERMINANTS OF SURVIVAL IN AIDS: ROLE OF CYTOMEGALOVIRUS, CD4+ AND CD8+ LYMPHOCYTES.

Fiala,Milan*, Cone,LA*, Schwartz,L*, Kermani, V**,Tourtellotte WW***. *Eisenhower Medical Center,Rancho Mirage,CA;**Immunobiogene, Los Angeles,CA;***VA Wadsworth Hospital, Los angeles, CA, USA.

Objective. To study virologic and immunologic characteristics of patients surviving over 1 year first AIDS-defining event.
Methods. Sixty patients admitted with AIDS to Eisenhower Medical Center have been followed and the survivors evaluated by serum p24 antigen,polymerase chain reaction and culture for CMV viremia, lymphocyte flow cytometry and ophthalmological examinations. Since 1987 the survivors have been treated with zidovudine and, since 1988, two also with human erythropoietin.
Results. All 24 patients with CMV retinitis have died (median survival of 166 days) and 28 of 36 patients without retinitis died (median survival of 302 days: Cox probability of survival in the 2 groups = 0.034). The survivors have been free of CMV retinitis (except for one patient with inactive retinitis), and have had undetectable HIV p24 antigenemia, median count of 60 CD4+ cells/mm^3, median count of 537 CD8+ cells/mm^3, and CD8+/HLA DR+ double-bearing cells ranging 126(13%) - 556(37.5%)/mm^3. The patients dying with disseminated CMV infection had 31-202pg/ml of HIV p24 antigen, 0-9 CD4+ cells/mm^3, and 2-174 CD8+ cells/mm^3. The survivors receiving zidovudine have been stable except for severe anemia in the two patients which was corrected by recombinant erythropoietin in one case.
Conclusions. Survival in AIDS is associated with absence of CMV dissemination and of HIV p24 antigenemia and with residual presence of CD4+ and CD8+ cells. Disseminated CMV infection is a major adverse prognostic factor in AIDS.

W.A.P.78

PREDICTORS OF SURVIVAL FOR AIDS IN BARCELONA(SPAIN)

Batalla Juan, Gatell JM*, Caylà JA, Jansà JM, Plasencia A, Parellada N.
Inst. Municipal de las Salud, Barcelona, Spain.*Hosp. Clínico,Barcelona,Spain.

Objective. To analyze the predictors of survival of 289 AIDS patients from Barcelona (Spain) where the relative percentage of drugs addicts is high and tuberculosis the most common initial manifestation of AIDS.
Methods. All adults (older than 14 years) but five with AIDS reported to the local health authorities were available for a longitudinal follow-up. Age, sex, group of risk for HIV infection, AIDS manifestation at diagnosis and the date of diagnosis were the variables included in the univariate analysis (Kaplan and Meyer survival curves) and in the multivariate analysis (Cox regression model for censored survival data).
Results. 246 (85.1 %) were males and 25 (8.6 %) were older than 45 years. 154 (53.3 %) were parenteral drug addicts, 100 (34.6 %) male homosexuals and the remaining 35 (12.1 %)were categorized as other. 16 of these 35 were hemophiliacs. 96 AIDS-cases (33.2 %)presented with a form of extrapulmonary tuberculosis, 148 (51.2 %) with another opportunistic infection, 34 (11.8 %) with a Kaposi Sarcoma and the remaining 11 cases with a lymphoma. 31 (10.7 %) were diagnosed before 1986. The survival probability dropped to 50% 385 days after diagnosis of AIDS. In the univariate analysis the survival probability was significantly greater in those presenting with a tuberculosis ($p < 0.0001$), among the drug addicts versus the remaining groups ($p = 0.0003$), in those diagnosed in 1986 or later ($p < 0.001$) and in those younger than 45 years ($p = 0.0001$). The multivariate analysis selected the year of diagnosis, group of risk, age and the initial clinical manifestation as predictors of outcome. The best prognosis was for drug addicts younger than 45 years presenting with a tuberculosis. Conversely the worse prognosis was for male homosexuals, hemophiliacs or recipients of a contaminated blood transfusion, older than 45 years and presenting with a Kaposi Sarcoma or with an opportunistic infection other than a tuberculosis.
Conclusion. The estimated survival probability of AIDS patients is not uniform from one geographical area to another and the best prognosis was for drug addicts younger than 45 years whose initial manifestation of AIDS was an extrapulmonary tuberculosis.

W.A.P.79

PREDICTING IN-HOSPITAL MORTALITY FOR AIDS PATIENTS: A VALIDATED MODEL.

Steven A Grover*, N Gilmore**, J Falutz*, C Tsoukas*, L Coupal*, R Fakhry*. *Montreal General and **Royal Victoria Hospitals, McGill University, Montreal, QC, Canada.

Estimating prognosis for a hospitalized AIDS patient is essential for optimal clinical management. We developed a prediction model for in-hospital mortality using admission data abstracted from 128 patient admissions to the Royal Victoria Hospital (RVH). This model was subsequently validated on 62 patient admissions to the Montreal General Hospital (MGH).

Using univariate analyses, stepwise logistic regression analyses, and clinical judgment, we identified independent predictors of in-hospital death including serum albumin (ALB) (β = -1.32), serum lactate dehydrogenase (LDH) (β = +0.0047), and leukocyte count (WBC) (β = +0.27) (all p's<0.05). High, medium, and low-risk groups for in-hospital mortality were defined where the probability of dying was set at 100%, <100% to >5%, and ≤5% respectively. Using the resulting RVH regression scores and 2x2 contingency table analysis, we determined the cutoff scores that corresponded to the above risk groups. The validity of the RVH model was then tested by classifying admissions at MGH. In-hospital mortality for the high, medium and low-risk groups was 100% (2/2), 42% (10/24) and 14% (5/36) respectively.

We conclude that routine admission laboratory tests associated with inanition (ALB), pneumocystis pneumonia (LDH), and other infections (WBC) help predict the outcome of hospitalizing patients with AIDS.

W.A.P.81

IMPROVED SURVIVAL OF AIDS PATIENTS IN DALLAS, TEXAS AFTER 1986.

Haley, Charles E; Reff V, Freeman A, Haslund I, Karpf K, Bierman M.
Dallas County Health Dept, Dallas, TX, USA.

Objective: To determine survival among AIDS patients in Dallas.
Methods: Diagnosed AIDS patients have been reported to the Dallas County Health Department since 1983. The registry has been maintained using standard methods; validation surveys verify the completeness of reporting. Survival analysis was performed using Kaplan-Meier product limit estimates.
Results: 1440 persons have been diagnosed with AIDS in Dallas between 1981 and 1988. Variables associated with survival include age at diagnosis, race, sex, and risk category. Among the 1044 homosexual males, aged 20-45, without a history of IV drug use, the median survivals for those diagnosed pre-1986, 1986, and 1987 are 305, 386, and 401 days, respectively; trends for 1988 indicate a longer median survival. The survival times for those diagnosed pre-86 were different from those for each of the other years (p<.01); the differences between the other years may have occurred by chance (p>.05).
Conclusions: There has been an improvement in AIDS patient survival. Potential reasons include "lead time bias" due to earlier diagnosis with the widespread use of HIV testing; antiviral therapy with AZT; or improved management of opportunistic infections. All three reasons may play a role in improved survival, but the effect for those diagnosed as early as 1986, before the widespread use of AZT, argues for lead time bias as an important factor.

W.A.P.83

SURVEILLANCE-BASED SURVIVAL ANALYSIS OF QUEBEC AIDS PATIENTS

Denis Roy*, Robert W. H. Palmer*, Robert S. Remis*
*Bureau régional des maladies infectieuses
Montréal, Québec, Canada.

Objectives: To assess survival of AIDS cases following diagnosis and to evaluate survival determinants and trends over time.

Methods: The vital status of the AIDS cases reported to January 15, 1989 was assessed through on-going follow-up of cases. Life-table analysis (product limit method) and the Cox proportional-hazards analysis were performed.

Results: Of the 743 cases diagnosed, 359 were known to have died. The median survival time following diagnosis was 9.6 months; the cumulative probability of survival at one, two and three years was 41%, 16% and 9.8%, respectively. Univariate analysis showed that survival was significantly shorter for children than for adult cases (7.0 vs. 9.8 months, p = 0.02). Among adult cases, there were no significant differences in survival by sex or age at diagnosis. Median survival time was significantly shorter for those born in a Pattern II country (8.1 vs. 10.0 months, p = 0.04). AIDS-related diseases were the strongest predictors of survival. The diagnosis of Kaposi's sarcoma (KS) was associated with longer survival (median 12.4 months, p < 0.001). By multivariate analysis, independent significant decreases in survival were found for age at diagnosis ≥ 30 years (relative risk (RR) of death at any time of 1.34) and for AIDS-related diseases when compared with the diagnosis of KS (RR = 1.52, 1.37 and 2.29 for Pneumocystis carinii pneumonia, other opportunistic infections and other AIDS-related neoplasms and syndromes, respectively). There were no significant temporal trends in survival.

Conclusion: Active surveillance of AIDS cases permitted the evaluation of survival after diagnosis. Our study did not find shorter survival among females or temporal improvements in survival but confirmed the positive association of KS and a younger age at diagnosis with improved survival.

W.A.P.80

EFFECT OF MULTIPLE DISEASE MANIFESTATIONS ON LENGTH OF SURVIVAL FOR AIDS PATIENTS IN SAN FRANCISCO

Payne, Susan F.; Lemp, GF; Rutherford, GW; Neal, DP; and Temelso,T. San Francisco Dept. of Public Health, San Francisco, CA, U.S.A.

Objective. To evaluate the effect of multiple manifestations of AIDS-indicative diseases on length of survival.
Methods. We evaluated survival following AIDS diagnosis for 4524 patients reported in San Francisco between July 1981 and Dec. 31, 1987. Cases were followed at 6-month intervals from diagnosis to death. 10% of cases were lost to follow-up. The number of AIDS-indicative disease manifestations occurring within 3 months of initial diagnosis was calculated, and median survival was calculated separately for patients with 1, 2, and 3 or more disease manifestations using the Kaplan-Meier product-limit method.
Results. The median survival for all patients was 12.5 months, with a 3-year survival rate of 8.8%. Survival decreased significantly as the number of separate manifestations of AIDS-indicative diseases increased. This trend was consistent for all patients regardless of initial diagnosis.

Median Survival by Number of Disease Manifestations

Initial Diagnosis	1 Disease N	1 Disease Survival	2 Diseases N	2 Diseases Survival	3+ Diseases N	3+ Diseases Survival	p-value
KS	1030	17.0 mos	150	9.5 mos	30	5.3 mos	<.001
PCP	2144	13.2	326	9.1	57	7.6	<.001
OOI	591	8.8	165	6.8	--	---	<.05
Total	3765	13.5	616	8.8	112	6.8	<.001

Conclusion. The occurrence of multiple disease manifestations within 3 months of initial AIDS diagnosis significantly decreases survival.

W.A.P.82

INCREASED SURVIVAL FOR PWA

Lafferty, William*; Glidden D; Hopkins S*; Harwell J*; Kenny J*; Fields B*
*Washington State Office on HIV/AIDS, Seattle; **Seattle/King County Department of Health, AIDS Epidemiology, Seattle, WA, U.S.A.

Objective: To monitor median survival time for people with AIDS (PWA) by diagnosis and diagnosis date.
Methods:: Recent death dates were searched by death certificate review of county vital records for surviving PWA. Kaplan-Meyer product limit survival analysis was applied to the statewide AIDS Surveillance database for cases diagnosed prior to 1988.
Results: Overall median survival for all 777 cases was 445 days. Median survival significantly increased for people with pcp and ks when cases diagnosed prior to 1986 were compared to those diagnosed in 1986, while no increases were seen during this time interval for people with other diagnoses. While significant increases were seen in all categories for cases diagnosed in 1987 compared to those diagnosed in 1986, the inclusion of dementia and wasting syndrome significantly prolonged survival in 1987. Cases with outpatient diagnoses survived significantly longer than other cases (1233 vs 445 days). Cases with definitive inpatient diagnosis of PCP also had increased survival over each of the time intervals (data not shown).

Dx Yr	n/# Survival	All	PCP	KS	Other Dx
≤1985	209 / 21	340	369	407	300
1986	239 / 25	407	447	717	251
1987	329 / 25	624	599	*	625/417**

Median Survival in Days

*1/2 of cohort still alive **Excludes dementia and wasting syndrome.

Conclusions: The increase in survival time of PWA is multifactorial and reflects improved medical care (i.e., AZT, PCP therapy), earlier diagnosis, and expansion of the CDC case definition. Updated information and the relative contribution of each of these factors will be estimated.

Prevention Through Partner Notification

W.A.P.84

SYPHILIS CONTACT TRACING IN A NEW YORK CITY STD CLINIC:IMPLICATIONS FOR HIV PARTNER NOTIFICATION

Lamanuca, Suzanne; Chiasson, M.A.; Ewing, W.E.; Schultz, S. and Stoneburner, R.L. New York City Dept. of Health, NY, NY, U.S.A.

Objective. To examine contact tracing among STD clinic patients with syphilis, a group at increased risk for HIV infection; and to describe implications for HIV partner notification by comparing the results of traditional contact tracing interviews (CTI) which require naming of partners with results of a confidential structured questionnaire (CSQ) where only the number of partners is requested.
Methods. Volunteers with diagnosed syphilis participated in a CTI performed by clinic personnel and also were enrolled in an HIV seroprevalence study where information on sexual behavior and risk factors for HIV infection were collected by an interviewer using a CSQ.
Results. Data from 64 participants were analyzed: 11 (17%) were prostitutes; 19 (30%) reported prostitute contact; 6 (9%) reported iv drug use and 6 (9%) were HIV antibody positive. On CTI, 22 (34%) gave no information identifying contacts. There was a significant difference (p<.001) between number of contacts given in CSQ and CTI: 41 (64%) gave a larger number, 20 (31%) gave identical results and 3 (5%) gave a smaller number. Mean number of contacts for CSQ was 3.1 compared with 1.0 for CTI. From the CSQ, mean number of contacts for 3 months, 1 year, 3 years and since 1978 were 3, 7, 21, and 55, respectively.
Conclusion. These data suggest that HIV partner notification in New York City may be seriously hampered by partner anonymity, lack of locating information, and concerns for confidentiality.

W.A.P.85 SEXUALLY TRANSMITTED DISEASE (STD) CLINIC CLIENT OPINIONS ON HIV PARTNER NOTIFICATION

Spencer, N.*; Rasevsky, C.*; Wolf F.*, Simms, C.**
*Colorado Department of Health STD/AIDS Section, Denver, Colorado, USA,** University Hospital Health Sciences Center, STD Clinic, Denver, Colorado, USA.

Objective. Determine opinions on acceptance of HIV partner notification services by STD clinic clients.
Methods. Consecutive clients attending the University of Colorado Health Sciences Center STD clinic during October and November 1988 were asked to complete an anonymous 6 question survey.
Results. 212 clients responded to the survey (male 120, 56.6%; mean age 28.6; white 128, 60.4%). Almost all (206, 97.2%) felt a need for those exposed to HIV to be informed. Consistent results were obtained when questions were personalized; important to inform respondents partners (207, 97.6%), and respondent would want a trained professional to inform them (199, 93.9%). Over half (109, 51.4%) indicated difficulty in informing partners themselves yet most (171, 80.7%) would assist a person trained to do so. Respondents selected multiple factors of concern. Of 452 selections: 86 (40.6%) feared disclosure of their positive test result, 85 (40.2%) were concerned that partner be notified privately, 61 (28.8%) feared rejection by partner, and 43 (20.3%) feared harm by an angry partner.
Conclusion: STD Clinic clients recognize the need for and will participate in HIV partner notification programs. Greater participation can be expected if confidentiality concerns are addressed with the client.

W.A.P.86 CUBA: Study of sexual contacts of the HIV seropositive persons

Authors: Galban, E; Menendez,J; Gil,R and Terry,H
Ministerio de Salud Pública,Habana, Cuba.

The Cuban Program of struggle against AIDS has as a most important goal the study of the sex contacts of each case infected by HIV detected through our screening system. Each of these contacts is subjected to a serological examination for the HIV determination and the same time they are given educational advice regarding their future sexual behavior while waiting for the result or results of the examinations. In general, all contacts are kept under surveillance for a year starting from the date of the last sex intercourse with the index case, serological examinations being done quarterly, except for the espouses who are followed-up every threee months indefinitely we have been able to control 80% of the 1317 sexual contacts of the HIV seropositive persons. Male homosexual relations were infecting is 5.1%, while heterosexual ones were so in 10.4% and 3.4% of women who had sex intercourse with bisexual males were infected.

W.A.P.87 EPIDEMIOLOGIC BENEFITS OF HEALTH DEPARTMENT NOTIFICATION OF HIV EXPOSURE.

Wykoff, Randolph F; Jones, JL; Longshore, SL; Hollis, SL; Quiller, CB; Gamble, WB. The South Carolina Department of Health and Environmental Control. Greenwood, South Carolina, USA.

Objective: To determine if Health Department notification of HIV exposure (contact tracing) not only produces beneficial behavior changes, but also adds to the understanding of the epidemiology of AIDS in a given community.
Methods: Standard STD notification procedures were used, with an emphasis on targeting preventive education to the sex and needle-sharing contacts of HIV-infected individuals.
Results: 316 unique sex and needle-sharing partners of HIV-positive persons have been named in one Health District in the past 2 years. 207 (66%) were contacted, educated and offered testing. 202 (98%) agreed to be tested and 36 (18%) were HIV-positive. Only 6 (3%) of the 202 had been previously tested. 49% of the known HIV infections in our District have been identified by Health Department notification, 33% by private physicians and 18% by other sources. Of those exposed to HIV, 35 (27%) had only heterosexual exposure and 8 were infants. The age range of contacts was 14 to 74. We have been able to reclassify 3 HIV-positive men who denied major risk factors. Two dimensional mapping has lead to a clearer understanding of the transmission of HIV in our area.
Conclusions: Health Department notification of HIV exposure significantly expands understanding of the extent of HIV infection and identifies HIV exposure among untested high-risk individuals and among people outside the risk groups and age ranges usually associated with AIDS in the USA.

Prévention de la transmission par contact sexuel et par consommation de drogue
Preventing Transmission by Sexual Contact and Drug Use

W.A.P.88 INEFFECTIVENESS OF EDUCATION IN INTRAVENOUS DRUG USERS TO PREVENT HIV SEXUAL TRANSMISSION.

Jean-François Delfraissy, A. Levy, A. Abelhauser, D. Peneo, A. Blanc, F. Boué, J. Dormont
Hôpital Antoine-Béclère, 92141 Clamart, France.

Objective : To study the change in behaviour regarding the intravenous (IV) use of drugs, and the attitudes toward sexual preventive measure, in a group of HIV+ intravenous drug addicts (IVDA) in Paris Aera.
Methods : Between January 1986 and June 1986, 264 HIV seropositive drug users were enrolled follow up in a 3 years prospective study. Patients initially agreed to attend counseling sessions twice a year. Clinical and immunological HIV status were performed, twice a year. In parallel the subject attitudes toward preventive measures concerning the IV use of drugs and sexual behaviour were recorded every six months.
Results : On 264 patients only 206 were followed regularly during the 3 years study. They were 142 male and 64 female with a mean age of 24,3 ± 2,1 years. No significant date could be obtained on the proportion of patient which increased or decreased the frequency of injections neither the use of drugs at home or alone. A the second visit (6 months), 72 % regularly used unique needle or syringue, and 69 % used condoms during sexual intercourse. At the 6th visit (2 years 1/2), 61 % persisted to use unique injection material, but only 22 % always used condoms. These attitudes toward preventive measures were equally observed in male and female sub groups.
Conclusion : in contrast with changes in sexual behaviour observed in homosexual population, there is a relative ineffectiveness of education and counseling in preventing the sexual transmission of HIV infection in IVDA on a 3 year period.

W.A.P.89 RISK BEHAVIORS OF IV COCAINE USERS: IMPLICATIONS FOR INTERVENTION

Chitwood, Dale, D.*; McCoy,C.B.*; Comerford,M.*; Trapido, E.J*. *University of Miami School of Medicine, Miami, FL. USA

Objective. Identify traits of intravenous cocaine use (IVCU) which are relevant for planning risk behavior reduction programs.
Method. Data from two tri-ethnic, male and female IVCU cohorts are presented. 1) To describe high risk traits of IVCU existing before AIDS was discovered, interview data collected in 1980-81 from 75 IVCUs are presented. 2) To describe current risk behaviors and attempted behavioral change to reduce HIV-1 exposure, data collected in 1987-88 from 255 IVCUs are presented.
Results. Prior to knowledge that AIDS existed (1980-81), IVCUs reported several high risk traits-cocaine obsession (68%), use escalation (61%), no spending limits (72%), cocaine-related money problems (82%), always craved cocaine (72%), never refused cocaine (44%), prostitution (47%) or traded sex (45%) for cocaine.
Current IVCUs were twice as likely (21%) as other IVDUs (10%) to test HIV-1 AB+. 70% reported risk reduction efforts, but a majority still injected daily, shared needles, had IV and non-IV sex partners (SPs), never used condoms. Attempts to stop sharing (20%) or share less often (22%) were reported by more IVCUs than shooting cessation (5%) or needle cleaning (13%). Reduction in number of SPs was reported more often (23%) than increased condom use (11%).
Conclusion. Many IVCUs engage in high risk behavior. Self-initiated attempts to change both needle use and sexual behavior often are unsuccessful. Implications for intervention programs are discussed.

W.A.P.90

TRENDS OF RISK REDUCTION AMONG INITIATES INTO INTRAVENOUS DRUG USE 1982-1987.

Vlahov David, Anthony, JC. Celentano, DD., Solomon, L., Choudbury, N., Mandell, W. The ALIVE Study. Johns Hopkins School of Hygiene and Public Health, Baltimore, MD, USA.

Objective. The purpose of this study is to identify and compare initial injection practices of IVDUs by year first used to determine if initiation practices have changed during the course of the epidemic.
Methods. As part of the baseline questionnaire for a natural history of HIV infection (ALIVE): active IVDUs recruited from the community were asked to report year first injected, drug first used, and the frequencies of injection, using sterile needles, sharing needles and cookers during their first three months of use. The distribution of responses were dichotomized and grouped by year first used. The chi square test for trends was performed.
Results. Of the first 1840 participants, 421 reported initiation between 1982 and 1987. Over these years, heroin as the first drug decreased ($p < .01$), while cocaine increased ($p < .05$). The proportion who never used sterile needles decreased ($p < .05$) as did the proportion who always used needles after another person ($p < .05$). The proportion who had > 1 needle sharing partner decreased ($p < .01$).
Conclusion. Although these data are from a cross-sectional report, they suggest a shift from heroin to cocaine and a shift toward lower risk practices among new IVDUs between 1982 and 1987.

W.A.P.92

SEXUAL BEHAVIOURS AND CHARACTERISTICS OF 627 GAY AND BISEXUAL MALE PARTICIPANTS OF THE TALKING SEX PROJECT - SMALL GROUP EDUCATIONAL INTERVENTIONS FOR THE PREVENTION OF AIDS.

Tudiver, Fred*; Myers, T.***; Kurtz, R.***; Jackson, E.*; Orr, K.*; Rowe, C.**.
*AIDS Committee of Toronto, Toronto, Ont., Canada, **Sunnybrook Medical Centre, Toronto, Ont., Canada, ***University of Toronto, Toronto, Ont., Canada.

Objective. To describe demographics, knowledge, attitudes and sexual behaviours of the 627 participants at time of recruitment into the study.
Method. A non-clinical study population was recruited from the community by a variety of methods. Subjects completed questionnaires prior to random assignment to control or 1 of 2 educational intervention groups.
Results. The mean age was 32.4 years (range 14 - 72); 56% had completed college or university; 40.6% had been HIV antibody tested; 10.8% were seropositive and 6.3% reported AIDS or AIDS related illness. Sexual practices reported for the prior 5 years and 3 months are:

Sexual practices	Condom		No condom	
	5 Years	3 Months	5 Years	3 Months
Anal Intercourse - Receptive	63.8%	36.2%	69.1%	16.5%
Anal Intercourse - Insertive	68.4	41.6	73.5	18.9
			5 Years	3 Months
Oral-Genital - Insertive			98.4%	84.1%
Oral-Genital - Receptive (with cum in mouth)			78.2	26.6
Mutual Masturbation			98.9	91.3

Conclusion. Although there may be problems with recall bias and the methods used, there appears to be a decrease in unsafe sex practices in the study population over the course of the past 5 years.

W.A.P.94

ONGOING IMPACT EVALUATION OF THE CONDOM USE PROMOTION/DESENSITIZATION PROGRAM FOR PREVENTING AIDS IN THE DOMINICAN REPUBLIC.

Guerrero, Ernesto; De Moya, E.A.; Rosario, S.
PROCETS, Ministry of Public Health, Santo Domingo, Dominican Republic.

Objective. To evaluate the Dominican Republic Condom Use Promotion/Desensitization Program (1987-1989) and to analyse its main impact on population groups.

Methods. Condom use adoption before and after program implementation has been assessed through: 1. A series of CAP studies with female sex workers and their clients, trasvestite, gay and bisexual men, jail inmates, haitian migrant workers and the general population; and 2. Periodic unobtrusive surveillance of hotel and motel rooms where condoms are made universally available.

Results. Positive attitudes toward condom use have increased from 55% in 1985 to 75% in 1988. Condom use in 1986 was less than 2% in the sexually active male population and less than 1% in female sex workers (FSW). By 1988, condom use in motels and hotels was 18%; FSW carrying condoms in their purses, has grown to 75%.

Conclusion. Creating and maintaining a permanent state of awareness of AIDS and aggressively enhancing the perceived value of condom use has significantly increased condom use in the Dominican Republic.

W.A.P.91

SELF EFFICACY AND COMMUNITY NORMS PREDICT AIDS RISK REDUCTION AMONG GAY AND BISEXUAL MEN IN SAN FRANCISCO: THE AIDS BEHAVIORAL RESEARCH PROJECT

McKusick, Leon*, Coates, TJ*, Morin, S.*
*University of California, San Francisco, CA, U.S.A.

Objectives. To describe correlates and predictors of reductions in high risk sexual behavior among gay men in San Francisco.
Methods. Subjects were 440 men in the AIDS Behavioral research Project responding to annual surveys since 1984. Subjects responded to mailed surveys regarding sexual behaviors, relationship status, antibody testing experience, and variables from our AIDS Risk Reduction Model (AARM). Variables measured in 1984 to predict risk behavior in 1987 included serostatus, AIDS prodromal symptoms, AIDS loss, relationship status, perceived social norms, and health belief (self-efficacy, threat, knowledge). Multiple logistic regression was used to derive adjusted odds ratios for each variable.
Results. 60% of the men practiced high risk sexual behavior in 1984 (50% practiced unprotected anal intercourse). Only 30% practiced high risk behavior in 1987 (12% practiced unprotected anal intercourse). Individuals in primary gay relationships and low in self-efficacy (perceived ability to reduce AIDS risk) practiced high risk behavior in 1984. Individuals who continued to practice sexual risk for AIDS between 1984 and 1987 were more likely to perceive that peers continued to practice high risk behavior (Adjusted odds ratio =1.12, $p=.05$). Those high in personal efficacy (adjusted odds ratio= .95, $p< .05$)and who tested positive for antibodies to HIV (adjusted odds ratio=.42, $p=.05$) were less likely to continue the practice of high risk behaviors in 1987. Conclusions. AIDS risk reduction campaigns may benefit from methods for increasing personal efficacy through skill training.

W.A.P.93

PRELIMINARY ANALYSIS OF FACTORS ASSOCIATED WITH COMPLIANCE WITH GUIDELINES FOR PREVENTION OF SEXUAL TRANSMISSION OF HIV IN HETEROSEXUAL COUPLES

Nichols, Margaret, Paroski P., Sampson G., Leibel J., Kennedy M.J. - Woodhull Medical and Mental Health Center, Brooklyn, NY, USA.

Objective. To present a preliminary analysis of factors associated with compliance with guidelines for prevention of sexual transmission of HIV in a cohort of monogamous couples.
Methods. The Northern Brooklyn Partner Study, begun in September 1988 with funding from the CDC, is a three year longitudinal study of monogamous heterosexual couples in which one partner has as his/her only risk factor sexual contact with the other partner. The sample is drawn from a community based primary health care facility which services a population that is 93% black or Hispanic and 86% IVDU's and their sexual partners. Data gathered are retrospective as well as prospective, and include sexual and drug use behaviors, psychological measures, and medical parameters (stage of disease of index partner, p-24 antigen, HIV cultures, concurrent VD, etc). All subjects are reinterviewed and examined at 3 month intervals.
Results. Preliminary data presented here will be a comparison between couples who are following "safer sex" guidelines versus couples who are not. The dimensions used for comparison include knowledge of HIV transmission, perceived threat of infection, perceived self-efficacy (the feeling that one has control over ones health), self-esteem, depression, perceived distance from AIDS, partner/peer support, and quality of the relationship.
Conclusion. These results indicate that some of the variables that are relevant in AIDS prevention for gay men are not relevant in the setting of heterosexual transmission in an impoverished minority community.

W.A.P.95

AN EVALUATION OF THE EFFECTS OF VARIOUS LUBRICANTS ON LATEX CONDOMS

Pugh, Bradley; Englert, M.
Ansell Incorporated, Dothan, AL, U.S.A.

Objective. To determine if short-term exposure to lubricants adjunctly applied to latex condoms can cause sufficient deterioration to warrant concern about condom failure during use.
Methods. Latex condoms were exposed to various adjunct lubricants mentioned as being used by the public as extra lubrication for condoms. Samples were exposed to lubricants in one experiment for ten minutes at body temperature and in another experiment for one hour at room temperature and then tested for tensile strength according to ASTM Standard test methods. A control group, without exposure to any lubrication, was subjected to the same testing.
Results.

Lubricant	Tensile (MPa) (Body Temp.)	Tensile (MPa) (Room Temp.)	
No lubricant (control)	33.6	33.6	ASTM Std.
Vegetable oil	16.1	6.4	Tensile
Petroleum jelly	15.9	11.6	min. = 17 MPa
Personal lubricant	14.2	11.0	

Conclusion. Some personal lubricants sold in sex shops and other household items (petroleum jelly, vegetable shortening) have a significant deleterious effect on the strength of condoms. This deterioration is severe enough and occurs rapidly enough that their addition to latex condoms as adjunct lubricants is likely to cause the product to fail during use. Only water-based or silicone-based lubricants or others that have been tested and recommended by the condom manufacturer should be used.

W.A.P.96

EVALUATION OF CONDOM UTILIZATION AND ACCEPTABILITY OF SPERMICIDES AMONG PROSTITUTES IN KINSHASA, ZAIRE

Nzila,Nzilambi*; Laga, M.***; Kivuvu, M.*; Mokwa, K.*; Manoka, At.*; Ryder, R.*/**; *Projet SIDA, Kinshasa, Zaire, **CDC, Atlanta, GA, ***Institute of Tropical Medicine, Antwerp, Belgium.

Objectives. To evaluate the effectiveness of a condom intervention program and to evaluate acceptability of spermicides in Kinshasa prostitutes.

Methods. From June-December 1988, 801 prostitutes were interviewed about knowledge, attitudes and practices of condoms at entry of an STD/HIV survey, and again 3 months after announcement of the results, counselling and free condom distribution. 210 HIV(-) women were interviewed, counselled and examined monthly for a total follow-up of 1054 months of observation. In a pilot demonstration project, 25 women were offered spermicides.

Results. At entry, 3% of women reported "always" condom use 27% "sometimes" and 70% "rarely" or "never". HIV seroprevalence was 27%, 37% and 39% respectively (p=0.6). After 3 months, 93% of women reported some condom use (50% always, and 50% inconsistently) independently of HIV serostatus. Seventy % of non-use of condoms was attributable to clients refusal. The reported condom use of 140 women followed up prospectively was validated with incidence of STD, presence of sperm on vaginal smear and incident pregnancies. Out of 8 women who seroconverted, 1 was a consistent condom user(C.C.U) and 7 were inconsistent condom users (ICU) (p)0.5).

	CCU (n=39)	ICU (n=101)	
Incidence of:			
N. gonorroeae*	0.7	1.6	0.02
T. vaginalis*	1.4	1.7	NS
Spermatozoides*	0.5	0.5	NS
No. of new pregnancies	3 (7.7%)	8 (7.9%)	NS

(* expressed as episode per woman year of observation)

Spermicides (Benzalkonium ovules) were used in 92% of client encounters, were well accepted and were associated with not side effects.

Conclusions. Condom use increased considerably after intervention but STD and HIV transmission persisted despite high reported condom use. Spermicides are highly acceptable among prostitutes.

W.A.P.97

AIDS AND CONDOM-USE IN THE NETHERLANDS

Ernest M.M. de Vroome *, Th.G.M. Sandfort *, M. Paalman **, R.A.P. Tielman *
* University of Utrecht, ** STD Foundation, Utrecht, Netherlands.

Objective. Since May ´87 a number of campaigns directed at the general public were undertaken. The levels of knowledge, attitude and behavior among heterosexuals before and after the campaigns are examined.

Methods. Data were collected by semi-annually interviewing approximately 1000 respondents (age 15-45). Interviews were done by telephone, respondents were randomly sollicited in each of the four surveys.

Results. From May ´87 to Oct. ´88 (figures from the fifth survey (April ´89) will be presented as well), people associating "Safe Sex" with condoms (as intented by the campaigns) rose from 43% to 82% ($p<.0001$). It was confirmed that condoms protect against AIDS by 98% in Oct. ´88 compared to 74% in April ´87 ($p<.0001$). The overall attitude regarding condoms became more positive: the number of people saying the advantages of condoms prevail, increased from 62% to 78% ($p<.0001$). Among people having non-steady sexual relationships, condom-use increased from 30% to 77% ($p<.0001$), although not all these users used condoms consistently.

Conclusion. A number of changes have occurred, presumably supported by the conducted campaigns. Condom-use has become relatively more acceptable and more people associate the prevention of HIV-infection with the use of condoms. People with non-steady sexual relationships now use condoms more often, although part of this risk-group still doesn´t use condoms or doesn´t use them consistently.

W.A.P.98

THE SUPPLY OF, AND DEMAND FOR, CONDOMS TO PREVENT HIV TRANSMISSION IN DEVELOPING COUNTRIES

Kangas,Lenni W.;Harris,J.R. and Shelton,J.D.
U.S. Agency for International Development, Washington, D.C. U.S.A.

Objective.To assess the supply of, and demand for, condoms in preventing HIV transmission in developing countries.

Methods.U.S. Agency for International Development (A.I.D.) funding and shipping data were reviewed for Fiscal Years 1987-1989.Worldwide condom prevalence data were analyzed.

Results.Since 1987, A.I.D. has been the leading provider of condoms for developing country AIDS control programs.A.I.D. funds have bought 172 mil. condoms and over 120 mil. have been shipped to 56 countries. 48% of all condoms have gone to Africa, 27% to Asia, and 24% to Latin America and the Caribbean.Demand is increasing and half of all shipments were in the past six months.

Conclusion.Condoms can play a vital role in preventing HIV transmission.Current supply and demand are too low to significantly impact on the pandemic.If all 120 mil. condoms shipped had gone to Nigeria, less than 6% of Nigeria's 22 mil. males ages 15 to 49 years would have condoms for one year.To make enough condoms available, other donor resources are needed. Increasing the demand for condoms requires urgent attention.In developing countries, only 3% of reproductive age couples use condoms;in Africa, 0.5% do.Social marketing and private sector distribution must complement government efforts.Given the absence of vaccines and curative treatments, condoms are the world's most promising technology to prevent transmission of HIV.

W.A.P.99

PERSISTENT CONDOM BREAKAGE

Voeller, Bruce.*
*Mariposa Foundation, Topanga, CA, USA.

Objective. To assess why males well informed in condom usage repeatedly broke condoms during post-penetration coitus.

Methods. Several hundred males who had condoms break during coital use were screened. 25 (a) correctly answered all questions about proper use of condoms, but (b) reported breaking condoms more than 10% of the occasions used. Further interviews attempted to ascertain a cause for such high breakage.

Results. About one third of the men practiced vaginal intercourse; the remainder anal intercourse. All 25 men claimed only to use "water-based" lubricants, never using "oil-based" ones. Yet, 23 identified their usual coital lubricant as Vaseline Intensive Care hand lotion, Johnson's Baby Oil, or Nivea Hand Creme. Each of the 25 men believed these lubricants were "water-based" because they were readily washed away in tap water, in contrast to lubricants such as Vaseline Petroleum Jelly, Crisco or butter. All 25 men were U.S. college graduates.

Conclusion. These data suggest that differences in frictional stress between anal and vaginal intercourse may not suffice to account for breakage. Coupled with the reported rapid deterioration of condoms caused by mineral-oil sex lubricants, the data suggest that some portion of coital breakage of condoms may be based in the conscientious users' misconception that baby oil and emulsified oil lubricants are "water-based." Better choice in language may be important for condom use brochures.

W.A.P.100

INCREASING CONDOM ACCESSIBILITY: WHAT ARE THE BARRIERS?

Spencer, Brenda, Spira A., Job-Spira N.
U292 INSERM, Paris, France.

In both research and promotional campaigns, condom promotion is usually characterised as a problem of attitude and behaviour change at the level of the individual i.e. as a question of acceptability. Far less attention has been paid to the question of accessibility. Yet, applying the experience of previous campaigns and simple marketing principles, this is a key issue. In France condoms may be obtained in pharmacies and large supermarkets. The range of other outlets is negligible, nonetheless, companies attempting to install vending machines report having met with great difficulties. Given the high rate of HIV positivity in France and the traditionally low rate of condom use, this situation appears paradoxical. Our research programme therefore aims to identify the barriers to achieving a wider availability of condoms - at the level of the general public, institutions and business. We report here on acceptability to the public of new retail outlets and of vending machine installation in a range of possible sitings. The survey was conducted through two sources: a questionnaire in a high distribution TV magazine, and a national representative sample with a polling organisation. Results show overall acceptance of wider distribution to be high among all ages and all socio-economic groups. There was no preference for sitings in toilets. The two proposed sitings with an acceptability markedly lower than the rest (around 50%) were the workplace and public buildings. Other sites, including universities, highschools, bars, stations, leisure centres, health centres and the street, had acceptance levels between 70-90%. We infer that the major barriers lie elsewhere than with the general public.

W.A.P.101

A SIMULATED PHYSIOLOGIC TEST OF LATEX CONDOMS

Herman, W.A., Retta, S.M., Rinaldi, J.E., Herman, Bruce A., Carey, R.F., and Athey, T.W.
Division of Physical Sciences, Center for Devices and Radiological Health, FDA, Rockville MD 20857 USA.

Objective. To test latex condoms for the passage of HIV-size microspheres under simulated physiologic conditions.

Method. HIV is simulated by uniform, polystyrene, fluorescent microspheres with mean diameter of 0.11 μm. These microspheres are suspended in physiologic phosphate buffered saline with surfactant. The condom is unrolled onto a form and inserted into a fabric mesh which limits the expansion of the condom to physiologic dimensions. The form with the condom and fabric mesh is secured in a test chamber and the condom filled with the suspension of microspheres under a static pressure of 60 mm Hg, which was found to be the maximum pressure difference across a condom in modelling experiments performed in our laboratory. The chamber is filled with the same solution, less the fluorescent microspheres. The test system is maintained at a temperature of 37°C and a pH of 7.0, while the chamber's fluid is continuously monitored for the presence of the fluorescent marker.

Results. The test system has quantitatively identified laser-induced holes as small as 8 μm in diameter and is capable of detecting holes as small as 3 μm. Tests of 69 condoms from 2 manufacturers found 6 condoms which passed microspheres. The leak rates corresponded to hole diameters in the range 4 μm to 7 μm.

Conclusion. This test is sufficiently sensitive to determine whether condoms provide an effective barrier to HIV-size microspheres under (static) physiologic conditions.

W.A.P.102 INACTIVATION OF HIV-1 IN VAGINAL AND SEMINAL SECRETIONS BY THE SPERMICIDE BENZALKONIUM CHLORIDE.

Vainberg, Mark A.; and Thomas, R.
Jewish General Hospital and Clinique l'Actuel, Montreal, Quebec, Canada.

Objective: To determine whether benzalkonium chloride could destroy infectiousness of HIV-1 in body fluids.
Methods: Vaginal and seminal secretions were obtained from each of 4 male and female patients with advanced HIV disease. The cells in these fluids were harvested and co-cultured with cord blood lymphocytes to yield progeny HIV after 10 days. At the same time, aliquots of body fluids were exposed to concentrations of the drug that had previously been shown to inactivate HIV in tissue culture (0.01%). After varying times, the cells in these treated body fluids were harvested and co-cultured as described above.
Results: Exposure of seminal and vaginal fluids to 0.01% drug for 10 minutes eliminated the presence of detectable, infectious HIV-1. Exposure to drug for lesser periods was without significant effect
Conclusion: Benzalkonium chloride may have usefulness as a disinfectant against HIV-1.

W.A.P.103 The relationship between condom use and sexual behaviour.

J.M. Sandet, I.L. Kvalem, P. Magnus, J.K. Grunnesby, H. Stigum, L.S. Bakketeig
National Institute of Public Health, Department of Epidemiology, Oslo, Norway.

Condom use is propagated as an effective measure against infection of HIV and other STD's. The aim of this presentation is to relate data on the frequency and pattern of condom use in the Norwegian population.
Methods. The results are based on the responses to an anonymous postal questionnaire sent to a simple random sample of 10.000 Norwegians between 18 and 60 years of age in november 87. The response rate was 63%. Except for educational level, the respondent group is fairly representative.
Results. Married subjects without extramarital affairs during the past three years report more often use of condoms in their last intercourse with their spouse (12.4%) than those with extramarital affairs (7.3%). 8.7% reported use of condoms in their last intercourse with extramarital partner. Among singles, 15.8% used condoms in their last intercourse. When their last partner was a prostitute, about 50% of both married and singles reported use of condoms. Condom use is more common among young people, whereas there are no appreciable gender differences. Subjects who report use of condoms in the last intercourse tend to have lower partner turnover and higher sexual debut age than those who do not.

W.A.P.104 NEEDLE-SHARING AND BLEACH USE AMONG INTRAVENOUS DRUG USERS (IVDUs) SEEKING TO ENTER AN ACUTE DETOXIFICATION PROGRAM

Hopkins, Sharon*; Carlisle M**; Honey J*; Harris N*; McGough J*. *Seattle-King County Department of Public Health; **Division of Alcohol and Substance Abuse Services; Seattle, Washington, USA.

Objective. As a baseline measure for AIDS control strategies, we sought to characterize needle-sharing and use of bleach for needle disinfection by IVDUs seeking to enter a county acute drug detoxification facility.
Methods. The intake counselor administered a questionnaire at the initial meeting with an IVDU, prior to AIDS risk reduction counseling.
Results. From 9/88 through 12/88, 226 consecutive IVDUs were interviewed. Two-thirds were male. Ninety percent described themselves as heterosexual, 7.5% homosexual (12 male, 5 female), 3% declined to answer. Heroin was the most common primary drug injected (60%), followed by cocaine (26%) and amphetamines (10%). Of the primary heroin users, 81% also used cocaine.

Sixty-five (29%) were currently sharing needles--with spouse or lover (28%), friends (48%), and other than spouse or friends (23%). Of the 65 needle-sharers, 63 had heard of using bleach to disinfect needles but only 42 (65%) currently used it. Of the 23 IVDUs sharing needles but not using bleach, the most common reason given was lack of access to bleach. Additional 1989 data will be presented.
Conclusions. We found that recent needle-sharing was relatively common in this population of IVDUs. Almost all persons sharing needles had heard of using bleach. This knowledge, however, was not consistently translated into behavior change in that over one-third of needle-sharers were not currently using bleach, primarily due to lack of access. These data support the need for expansion of programs providing bleach and motivation for its use.

W.A.P.105 OUTCOMES OF AN AIDS PREVENTION PROGRAM FOR METHADONE MAINTENANCE PATIENTS

Magura, Stephen*;Siddiqi, Q*; Shapiro, JL*; Grossman, JI*; Lipton, DS*; et al.
*Narcotic and Drug Research Inc., New York, New York, USA.

Objective: To implement and evaluate the outcomes of a comprehensive AIDS prevention program for methadone patients. The hypotheses were that the program would: increase knowledge of AIDS risks, heighten awareness of susceptibility to AIDS, increase sense of self-efficacy in avoiding risk, improve attitudes towards condom use, and prevent or decrease intravenous drug-using and sexual risk behaviors.
Methods: The program was conducted in 3 methadone clinics in New York City during 1987. Patients in clinic #1 were offered (in sequence) an AIDS education seminar, HIV antibody testing and facilitated peer support groups. Patients in clinic #2 were offered education and peer groups, but not testing. A random sample of patients in clinic #3 were non-intervention controls. Numbers were: AIDS education (N=197), HIV-ab testing (N=38), peer groups (N=51), controls (N=92). The outcome variables were measured at 3 times: baseline, 2 months after AIDS education, and 2 months after testing and/or peer groups.
Results: Multiple regression analyses were conducted. AIDS education was associated with increased knowledge of AIDS risks (p=.02) and with improved attitudes toward condoms (p=.09). Peer groups were associated with improved attitudes toward condoms (p=.05) and increased condom use (p=.01). Learning of HIV-ab seronegativity was related to increased self-efficacy (p=.03) and decreased IV drug-using risk behaviors (p=.05). Minority subjects increased condom use more than whites (p=.01).
Conclusion: Methadone treatment programs should adopt and develop further these AIDS preventive interventions.

W.A.P.106 ANTHROPOLOGICAL AND EPIDEMIOLOGICAL OBSERVATIONS OF CHANGES IN NEEDLE USE AND NEEDLE SHARING PRACTICES FOLLOWING TWELVE MONTHS OF BLEACH DISTRIBUTION

Margaret M. Connors, Lewis, B.F., Spectrum House, Inc. Westboro, MA, U.S.A.

Objective. To access the impact of an AIDS outreach program on IVDU risk-related behavior change through the collaboration of epidemiological and ethnographic methods.
Methods. In 12 months, 2000 self-sealed reuseable viles of bleach solution and 3000 condoms were distributed to IVDUs with bilingual instructions for use in Worcester, MA. Distribution of change in risk behavior was followed through demographic data on 514 needle users requesting HIV testing. The context of change was monitored through observational conversation in the city's high drug use areas.
Results. Sixteen months of demographic data show a reduction in reported number of needle sharing partners, concurrant with AIDS outreach efforts. A change in risk perception of needle sharing has been documented through ethnography, while, at first use of the needle, only 12% of a sample of 65 active users considered needle sharing is major risk to health, at present this has increased to 77%. Based on epidemiological data, 34% more females than males have sex with other needle users, and 16% more females frequent shooting galleries. Ethnographic data further clarifies the context of female risk practices in its observation of needle sharing and use of galleries as networking techniques for securing protection and accessing drugs.
Conclusions. The collaboration of surveillance and ethnographic techniques is both an innovative response to the difficult task of accessing active users and an effective means of evaluating the impact of AIDS prevention strategies targeting this population.

W.A.P.107 EVIDENCE FOR RISK REDUCTION AMONG IVDU IN AMSTERDAM.

Hoek, Anneke van den; Haastrecht, HJA van; Coutinho RA.
Municipal Health Service, Amsterdam, The Netherlands.

Objective. To evaluate the impact of the general prevention campaign - inclu ding the syringe exchange program - on risk reduction among intravenous (IV) drug users (DU).
Methods. From December 1985 to April 1988 263 DU participated in a follow-up study (FS) and were asked about their injecting and sharing behavior and the use of the exchange program. A trend in behavior reported at 3 different visits was evaluated. As learning one's infection status may influence risk behavior, sharing behavior was also studied among IVDU distinguished by knowledge of test result (HIV-Ab - ; HIV-Ab + ; HIV-Ab ?). We also evaluated a trend in behavior reported by participants at intake (Dec85-Apr88) and this trend was seen as a prevention campaign (PC) effect. FS behavioral change was compared with PC behavioral change.
Results. No increase was seen in the proportion DU injecting nor in the frequency of IVD use. A strong decrease in risk behavior among current IVDU was found during follow-up: 55,9% reported borrowing ≥ 1x at the 1st visit and 16,3% at 3rd visit, lending ≥ 1x was reported by 44,0% and 8,4% resp. A similar strong decrease was found in the 3 HIV-Ab test result groups. Only a limited risk reduction was found at intake despite a general increase in the use of the exchange program.
Conclusion. The ample provision of clean syringes did not increase the IV use of drugs. As the reduction in sharing was mainly a FS effect and only a limited PC effect and independent of the HIV-Ab test result, we conclude that ample provision of needles and syringes alone is not enough to change the risk behavior of IVDU but intensive counselling is also needed.

W.A.P.108 CHANGES IN HIV RISK BEHAVIOUR IN DRUG INJECTORS ATTENDING SYRINGE-EXCHANGE PROJECTS IN ENGLAND AND SCOTLAND

Stimson, Gerry V., Donoghoe, M.C. and Dolan K.
Monitoring Research Group, Goldsmiths' College, London, UK.

Objective. To assess the impact of syringe-exchange projects on the injecting and sexual behaviour of injecting drug users. The study was part of the evaluation of government sponsored syringe-exchange projects.
Methods. Injectors attending 14 syringe-exchange projects were provided with information about HIV risks, given needles and syringes on an exchange basis, and condoms. Self-reported risk-behaviour was assessed with a prospective interview administered at two points in time with 142 clients who attended up to March 1988.
Results. Syringe-sharing in the previous 4 weeks dropped from 34% to 27%; using others' syringes (risk of infection) dropped from 25% to 19%; passing on syringes (risk of transmission) dropped from 30% to 25%. 79% sustained or adopted low or lower levels of syringe-sharing. Those with sexual partners in three months dropped from 77% to 69%; those with two or more partners dropped from 26% to 21%. Surveys of two comparison groups of injectors not attending syringe-exchanges showed higher levels of syringe-sharing; in the first survey (n = 220) 62% shared, in the second survey 3/4 months later (n = 114) 59% shared.
Conclusion. The evidence indicates that many syringe-exchange clients maintain low risk behaviours and others adopt them. There are some who resist change. The changes over three months are small, but support the argument that injectors can be helped to change their HIV risk behaviour. Comparison groups of non-attenders showed higher levels of risk behaviour.

W.A.P.109 DRUG TREATMENT CENTERS AS THE NUCLEUS FOR A PREVENTION-BASED CASE MANAGEMENT SYSTEM FOR INTRAVENOUS DRUG USERS

Gardom, Jessica, Jones, T.S., Hayden, C.H., Stern, H.A., Poppe, P.O., Bowen, G.S., Centers for Disease Control, Atlanta, GA, U.S.A.

Objective: To describe a model plan for prevention of HIV infection, sexually transmitted diseases (STD), and tuberculosis (TB) in drug treatment centers for use by States who are recipients of Centers for Disease Control (CDC) AIDS Prevention and Surveillance Cooperative Agreement funds.
Methods: Drug Treatment Centers (DTC) are under-utilized settings for providing preventive health care for people who are at high risk for HIV, STD, and TB, though CDC funds State health departments to prevent these diseases. A comprehensive approach for providing a full range of prevention activities in these settings was lacking. Consequently, CDC staff developed a model plan to facilitate joint planning and implementation of HIV, TB and STD prevention activities in DTCs.
Results: The essential components of this model include outreach, individual HIV/STD risk reduction counseling, onsite voluntary HIV and TB testing, directly observed TB preventive therapy, referral and expedited admission of intravenous drug users (IVDU) from other agencies, on-site or referral for contraceptive services, and partner notification of seropositives. Funding mechanisms and a detailed plan for implementation and evaluation of impact will be described. Evalation of impact of this model includes analysis of reports, number of clients enrolled, number of clients tested, and other significant variables.
Conclusions: Full adoption/implementation of this model provides the first steps for a prevention-based case management system for IVDUs who are at risk for TB and who may be infected with HIV.

Prévention : politiques et évaluation des programmes
Prevention: Policy Issues, Program Evaluation

W.A.P.110 CARA – A TOOL FOR AIDS PREVENTION

Belschner, Wilfried.
University of Oldenburg, Oldenburg, Federal Republic of Germany

Objective. CARA is the abbrevition for computer assisted risk management with regard to Aids. CARA is a tool for the prevention of the HIV-infection in a dialogue with the computer. Target groups are students and young adults. It consists of 2 parts:
Part 1: With this program the participants acquire the knowledge one should have about Aids.
Part 2: The participants get the oppurtunity to assess the risks of their particular lifestyles in the fields job, leisure/sports, traffic and sexuality.
The participants receive a feedback on the riskiness of their lifestyles, especially on the risky behaviors with regard to a HIV-infection.
Results. The program has widely proved its usefulness and efficiency in German schools. It is highly attractive to students. Teachers and Aids counsellors use it for the introduction of lectures on Aids and the preparation of personal communication.

W.A.P.111 SHORT AND LONG TERM RESULTS OF AN AIDS PREVENTION PROGRAM

Miller, Tim*; Booraem, C.**; Flowers, J.***; and Iversen, I.***.
*AIDS Response Project, Garden Grove, CA; **University of California, College of Medicine, Irvine; ***Chapman College, Orange, CA, U.S.A.

Objective. While there have been a growing number of AIDS prevention projects reported in the literature, few have contained outcome results and none have reported follow-up data.
Method. Employing a 21 item AIDS Prevention Test (APT) designed by the authors, which has previously demonstrated both reliability and Form A, B equivalence, 102 Ss in 10 successive Stop AIDS Workshops were invited to participate in a 3 month follow-up program. All Ss took Form A of the test prior to the workshop and Form B after. 52 agreed to retake Form B in 3 months, 27 actually returned the follow-up test. 15 of the follow-up Ss also returned a Form B evaluating them, filled out by their significant partner.
Results. The 27 Ss demonstrated increased knowledge (70.0 to 81.1% correct t(26)=3.12, p.<.002), a positive change in AIDS related attitudes (27.34 to 29.89, t(26)=2.84, p.<.004 [35 possible]), and a positive change in intended sexual behavior (16.00 to 20.56, t(26)=10.25, p.<.001 [21 possible]) from pre to post workshop. At 3 months, the Ss showed increased positive change in attitudes (31.56, t(26)=6.91, p. < .001) a slight reduction in actual behavior from post workshop intended behavior (19.68); however the behavior change from pre-workshop to follow-up was still significantly positive (16.00 to 19.68, 7(26)=6.91, p.<.001). The 15 tests filled out by partners verified the Ss self reported attitudes (33.00) and behavior (19.50). There were no significant correlations between knowledge, attitudes and behavior per se, but correlations between changes in these three were significant.

W.A.P.112 TRAINING THE HEALTH CARE PROFESSIONAL: THE AIDS REGIONAL EDUCATION AND TRAINING CENTERS PROGRAM OF THE HEALTH RESOURCES AND SERVICES ADMINISTRATION (HRSA).

Horner, June; Heffron,P;Martell,B;Moore,D; and Macher,A.
Division of Medicine, Bureau of Health Professions, HRSA,
United States Public Health Service, Rockville, Maryland, USA.

Objective. To establish regional education centers that will provide multidisciplinary training for health care professionals.
Methods. With a projected cumulative total of more than 300,000 AIDS cases by 1992, it is essential that health care providers be trained in the diagnosis, management and treatment of HIV-infected patients. The insufficient number of providers active in the care of AIDS patients presents a major gap in the health care delivery system. In recognition of this problem, the United States Congress appropriated funds to establish the AIDS Regional Education and Training Centers Program.
Results and Conclusions. To date, thirteen centers have been created. These regional education and training centers provide multidisciplinary HIV/AIDS training for health care personnel within the framework of the following three goals: 1) training community primary care providers to incorporate strategies for HIV prevention into clinical priorities as well as to diagnose, manage, and counsel patients and their families; 2) training individuals to serve as instructors in their local area; and 3) educating health care professionals in providing sensitive and integrated care of AIDS patients through the improvement of their understanding of the complexities of the disease.

W.A.P.113 OUTCOME OF HIV PREVENTION AND COUNSELING AT COOK COUNTY HOSPITAL, CHICAGO: A TWO YEAR FOLLOW-UP.

Seibert, D.; Cadena, R.; Hite, E.; Holder, L.; Sherer, Renslow; et. al.
The Cook County Hospital AIDS Prevention Service, Chicago, Illinois, U.S.A.

Objective: To evaluate the 1988 experience of a public hospital-based AIDS education and risk reduction program, and determine two year trends in client demographic data and counseling outcomes.
Method: Between November, 1986, and December 31, 1988, 3,100 persons at risk of HIV infection received HIV prevention counseling. In 1988, 2,084 people were counseled. Of these, 1,212 (58%) were men and 872 (41.8%) were women. 1,439 (69.1%) were Afro-American, 313 (15%) white, 308 (14.8%) Hispanic, 8 (0.4%) Asian, 6 (0.3%) American Indian, and 10 (0.5%) other; overall, 88.4% were minority. By risk behavior, 256 (12.3%) were gay/bisexual men, 22 (1.1%) were gay/bisexual IVDUs, 831 (39.9%) were hetero IVDUs, 37 (1.8%) were transfusion recipients, 175 (8.4%) was hetero partners of above, 175 (34.9%) were hetero with multiple partners, and 21 (0.9%) other.
Results: Trends in 1988 are shown by table I, and trends from 1987-1988 in Table II:

TABLE I: QUARTER OF 1988 / TABLE II: 1987 - 1988

GROUP	1st	4th	1988 % INCRS	'88 TOT	'87 TOT	2 YR INCRS
GAY/BISEX MEN	74	72	0%	256	180	+ 42%
WOMEN	191	252	32%	872	172	+ 407%
IVDU	129	311	141%	831	200	+ 415%
HETERO PRTNR AT RISK	17	71	317%	175	50	+ 250%

In 1988, 1,166 (55%) of those counseled received HIV antibody testing. 6 month questionnaires revealed significant behavior change in 75.6% of respondents in 1987; 1988 results will be shown.
Conclusions: Confidential culturally-sensitive HIV-preventive counseling reached 2,084 clients at risk at Cook County Hospital, of whom 88.4% were minority members. Large increases in women and IVDUs were observed. A majority of clients reported significant behavior change resulting from the intervention at 6-month follow-up.

W.A.P.114 APPLICATION OF METHODS/RESULTS FROM FAMILY PLANNING OPERATIONS RESEARCH TO AIDS PREVENTION IN AFRICA

Wawer, Maria J., Columbia University, N.Y., USA.

OBJECTIVES: To apply operations research (OR) methods derived from family planning, in developing effective programs for prevention of sexual transmission of HIV in Africa. METHODS: Family planning OR has developed and tested culturally appropriate, cost-effective strategies to increase access to and acceptability of contraception, including condoms, in Africa. To collect data for program development and monitoring, OR uses methods from epidemiology, demography, anthropology, and market research. RESULTS: OR projects identified unexpectedly high levels of contraceptive knowledge among males and females in African countries (knowledge levels above 80% in urban Niger and Burkina Faso, over 40% in rural Cote d'Ivoire and Senegal) and increasing use of methods, including condoms. Data have been used to develop innovative education and contraceptive delivery, such as distribution in Lagos markets and by traditional midwives in Sudan, where contraceptive prevalence rose from 9% to 26% in a rural area. OR is currently being applied to an AIDS education program in Rakai, Uganda, and elsewhere. CONCLUSIONS: OR is effective in the introduction and promotion of family planning in Africa. Like AIDS prevention, family planning touches on controversial and sensitive issues, including changes in sexual practices and condom use. OR will be useful in promoting behavior change and condom use for AIDS prevention.

W.A.P.115 DETERMINANTS OF AIDS POLICY PREFERENCE OF THE GENRAL PUBLIC

Ostrow, David* and Traugott, M.*
*University of Michigan, Ann Arbor, MI,USA.

Objectives: To analyze factors associated with preferences for alternative public policy options related to the behavioral control of AIDS.
Methods: Respondents were the 1540 adults interviewed by telephone in the 1987 Chicago area General Population Survey for AIDS (IV International Conference on AIDS, abstract No. 9100). Determinants of responses to the 16 questions relating to endorsement of specific policy alternatives included demographic variables, self-assessment of AIDS risk/harm, and attitudes toward homosexuals.
Results: Factor analysis revealed three clusters of policy option preferences: employment-based testing programs, government-sponsored education and service programs, aud compulsory public health measures. A unique combination of sociodemographic and attitudinal characteristics predicted each set of preferences. In all three cases, the level of homophobia of respondents was the strongest predictor of policy preferences.
Conclusion: Public information programs should consider the role of attitudes toward homosexuals as they may strongly influence the assimilation and use of new information about AIDS. Furthermore, public policy makers need to be aware of the attitudinal determinants of public support for various AIDS policy options.

W.A.P.116 SEXUAL BEHAVIOUR OF YOUNG ADULTS AND THE EFFECTS OF AIDS-PREVENTION CAMPAIGNS IN SWITZERLAND

Zeugin P.[**]; Dubois-Arber Francoise[*]; Hausser D.[*]; Lehmann Ph.[*].
[*] Institut Universitaire de Médecine Sociale et Préventive, Lausanne, Suisse; [**] IPSO, Zürich, Suisse.

This study is part of the overall evaluation of the Swiss prevention campaigns.
Objectives. To measure changes in risky sexual behaviours and use of condoms within the 17 to 30 years old resident population in Switzerland. To identify indicators measuring efficacy of prevention campaigns.
Methods. Interviews by phone on the basis of a standardised questionnaire. Interviews are designed to obtain valid responses regarding questionning within the intimate sphere despite others standing by. The quotas sampling design is stratified by place of residence (N = 3 times 1'200). Data have been collected at three points in time: February 1987 (t0) before the launching of the first STOP-AIDS campaign, October 1987 (t1) nine months thereafter and October 1988 (t2) eighteen months thereafter.
Results. The proportion of people having had occasional sexual contacts out of a monogamous relationship within the previous six months remains stable (18% at t0, 14% at t1, 15% at t2). However, the use of condoms during occasional sexual relationship has increased significantly: the proportion of people saying that they never use condoms diminishes (67% at t0, 38% at t1, 13% at t2). At the same time occasional usage increases (25% at t0, 45% at t1 and 58% at t2), so does consistent usage (8% at t0, 17% at t1 and 29% at t2). Beyond this observations other aspects of sexual behaviour confirm the tendency towards safer sex.
Conclusions. Young adults in Switzerland are the more and more numerous to protect themselves against AIDS in situations carrying a potential risk for HIV contamination.

W.A.P.117 EFFECTIVENESS OF THE SWISS AIDS PREVENTION CAMPAIGNS IN 1988

Hausser Dominique[*]; Dubois-Arber F.[*]; Lehmann Ph.[*]; Gutzwiller F.[**].
[*] Institut univ. de médecine sociale et préventive, Lausanne; [**] ISPM, Zürich, Suisse.

Under the slogan STOP-AIDS, a national multimedia campeign is continously conducted by the Federal Office for Public Health since 1986. Equivalent efforts are made stimulating multipliers to developp specific or local preventive actions. This program also includes a continuous and independant evaluation which have - to measure behaviour changes, - to identify factors which have positive or negative influences on changes, - to propose corrections or adaptations which could improve campaigns. Conclusions are based on 20 intercomplementary studies conducted in 1988 interviewing nearly 4000 persons of various groups of the population :
- Knowledges on AIDS (HIV transmission and protection) are good. There is still doubts on what is not dangerous (risk with saliva or blood transfusion in Switzerland).
- Health professionals generaly overestimate their professional risk. This create fear and further suspicious attitudes to some patients.
- There is no stigmatisation. Despite an apparent social consensus of non discrimination, casting out of persons are unfortunately observed occasionally.
- Adoption of protective behaviour is in progress but stay difficult. It's often related with emotional dimension of relationship. Condoms sale slowly increase (less than in 1987).
- Messages are clear, reach general population and target groups. Number of peripherical preventive actions have been developped, but still few efforts have been done for IVDUs. Social and health professionals have played very little preventive role.

W.A.P.118 MORE THAN ONE TYPE OF HIV EDUCATION AND TESTING PROGRAM IS NECESSARY TO REACH SELECTED TARGET POPULATIONS IN LARGE NUMBERS.

Sweha A*, Flynn N*, Nassar N*, Jain S*, Webb D+, Acuna G.++.
* University of California Davis,+ Sacramento County Health Department,++ AIDS-IVDU Task Force, Sacramento, CA, U.S.A.

OBJECTIVE To compare the populations being tested for HIV-1 ab in hospital setting, an Alternative Test Site (ATS) and Drug Treatment Programs (DTP). METHODS Demographic information was recorded from medical records of patients tested in clinics or in hospital, exclusive of AIDS clinic, from 1/86 - 8/87. Records of IV drug users were reviewed in detail. Information regarding ATS and DTP clients was obtained from the County Health Department (ATS) and our education/prevention program for IVDU (DTP).

RESULTS

	Hospital		ATS		DTP	
	N	S	N	S	N	S
Total	1169	9.5%	8891	7.1%	674	1.5%
Gay/Bisexual	88	44.0%	2927	19.4%	--	--
IVDU	541	5.7%	753	2.9%	577	1.7%
MSP*/Prostitution+	16+	12.5%	2756+	0.3%	--	--
Transfusion Recipients	67	7.4%	327	1.5%	--	--
Sex Partner of the above	--	--	1648	1.2%	80	0.0%
Unidentified	377	2.0%	480	0.02%	--	--
Others	120	24.0%	2	50.0%	--	--

S-seroprevalence, MSP- multiple sexual partners.

CONCLUSIONS: Different populations are found at different test sites. Access to all test sites is essential to reach different risk groups in large numbers with education and testing programs. They are complementary.

W.A.P.119 HOW CAN SEROPREVALENCE SURVEY DATA BE USED TO MANAGE HIV PREVENTION PROGRAMS?

Onorato, IDA*; Jones, T.S.**; and Forrester, W.*
AIDS Program* and Center for Prevention Services**, Center for Disease Control (CDC), Atlanta, GA, USA.

Objective. To guide health departments in utilization and limitations of CDC Family of Surveys (FOS) data in managing HIV prevention programs.
Methods. We analyzed survey methodology and procedures to assess potential biases in each type of survey data. Considering these limitations, we suggested appropriate uses of data in public health programs. A communication system for dissemination of data is proposed.
Results. No single seroprevalence survey is representative of the entire population. Biases were identified in each type of survey. Characterization of the population surveyed and adherence to standard CDC protocols will minimize biases. In prevention programs, CDC FOS data may be used in allocating resources and in determining the types of education, counseling and testing services offered. Over time, data will be useful in following trends in HIV infection and in evaluating the impact of program activities. Success in reaching infected persons may be measured by comparing seroprevalence rates in unlinked surveys with voluntary testing in the same population. Consultants in health departments and at CDC form a network for disseminating data to health care providers and program managers.
Conclusion. FOS seroprevalence data will be a valuable tool in surveillance and prevention of HIV infection. Awareness of the survey biases aids in interpreting results. A defined communication process is needed so prevention programs can access and utilize data effectively.

W.A.P.120 A PROGRAM TO ENCOURAGE AIDS PREVENTION COUNSELLING BY PRIMARY CARE PHYSICIANS

Wortman, J.**; Rekart, M.*, Gelfer, M.**
**College of Family Physicians of Canada, British Columbia Chapter, Vancouver, British Columbia, Canada, *Division of STD Control, Province of British Columbia, Vancouver, British Columbia, Canada.

Objective To alert primary care physicians to the importance of AIDS prevention counselling at the time of HIV-antibody testing.

Methods A travelling multi-media seminar was developed to alert physicians to their role in the prevention of AIDS. Epidemiological and risk information was included with advice on how to assess patients for risk of infection and need for testing. Models for pre-test and post-test counselling both HIV-antibody negative and HIV-antibody positive patients were presented. A questionnaire was administered to assess the impact of the presentation.

Results Approximately one in ten physicians in the province returned a questionnaire (n=601). The program cost was approximately $80 per physician reached.

- 90% had ordered one or more HIV-antibody tests
- 20% had dealt with one or more HIV-antibody positive patients
- 7% had tested without patient knowledge and/or consent
- 79% indicated the highest level of approval of the presentation
- 24% indicated they would test more often
- 96% indicated they will incorporate suggestions from the seminar into their approach to testing.

Conclusions A travelling seminar format is an effective method for alerting primary care physicians to their role in preventing AIDS through counselling

Th.A.P.1

PREVALENCE OF HTLV-1/HIV-1 INFECTION AMONG MALE INTRAVENOUS ABUSERS AND THEIR SEXUAL PARTNERS IN CHICAGO

Lentino, Joseph R.*; Pachucki, C.T.*; Schaaff,D*,Schaefer, M.*; Schroer, D**; Dorus, W.*; Hines Veterans Administration Hospital, Hines, IL.* Ortho Diagnostic Systems,Inc., Raritan, N.J.** U.S.A.

Objective:To determine the prevalence of HIV-1 and HTLV-1 infection in 150 IVDAs and 19 of their sexual partners.
Methods: Antibody to HIV-1 and HTLV-1 measured by repetitively reactive ELISA was confirmed by Western Blot, demonstrating antibody to >2 antigens.
Results:The prevalence of antibody to HTLV-1 was 8.66%(13/150) for the patients and 5.26%(1/19) among the sexual partners. Only 10 patients(6.66%) had antibody to HIV-1. Only 1 couple of 19 was noted to be antibody positive for HTLV-1 by repetitively reactive ELISA.However, on Western Blot assay, the patient's sera reacted with only 1 antigen,while his non-drug abusing spouse was confirmed positive. There were no statistical differences in the incidence of sexually transmitted diseases(STD's)among the HTLV-1 positive patients as compared to either the HIV positive patients or to a serologically negative control group drawn from the same population. Only one patient was positive for both HTLV-1 and HIV-1 as confirmed by Western Blot. CD4/CD8 lymphocyte ratios in HIV-1 infected patients,0.46±0.12,were significantly lower than ratios for HTLV-1 infected patients,1.17±0.17(p=0.006)or for non-infected control patients,1.35±0.13(p=0.001).Absolute CD4 lymphocyte counts were significanly lower among HIV-1 infected patients,802±225,as compared to HTLV-1 1680±293(p=0.032) and control patients 1859±278(p=0.007).
Conclusion:Prevalence of HTLV-1 in our non-endemic,geographic area was greater than that of HIV-1 in our cohort of patients. Infection with HTLV-1 was independent of HIV-1 infection or STD's.

Th.A.P.3

HTLV-1 EN FRANCE METROPOLITAINE

Lemaire, Jean-Marie*; Coste, J*; Courouce A.M.**; et le Groupe Rétrovirus de la Société Nationale de Transfusion Sanguine.
*CRTS - 34010 Montpellier, France ;**INTS - 75015 Paris, France

Objectif. Estimer la diffusion de HTLV-1 en France métropolitaine.
Méthodes. 4797 échantillons sériques (2319 donneurs de sang et 2478 sujets à risque ont été collectés en France métropolitaine. Les dépistages ont été réalisés par un test d'agglutination ou des tests immunoenzymatiques.
Les sérums positifs étaient confirmés par Immunofluorescence Indirecte et Western Blot.
Résultats.

Sujets	Nombre	Anti HTLV-1 positifs
I Donneurs de sang		
. Caucasiens	1274	0
. Originaires de zones endémiques	1045	7
II Sujets à risque		
. Polytransfusés	387	0
. Consultants pour MST	401	0
. Toxicomanes	1690	7

Conclusion. Les sujets contaminés par HTLV-I ont été retrouvés chez les toxicomanes (4p1000) et les donneurs originaires de zones endémiques (7p1000). La diffusion en France est donc rare, mais une surveillance régulière s'impose.

Th.A.P.5

HTLV-1 SEROPREVALENCE IN PATIENTS WITH HIV AND NEUROLOGIC DISEASE, OTHER RISK GROUPS, AND BLOOD DONORS, IN ZIMBABWE.

*Houston Stan, *Thornton C, **Emmanuel J, **Smith H. *Latif A. *University of Zimbabwe and **Blood Transfusion Service, Harare, Zimbabwe.

Rationale: HTLV-1 is associated with T-cell tumours and Tropical Spastic Paraparesis (TSP). Relatively high prevalence are reported from several African countries, but it has not been studied in Zimbabwe.
Methods: Commercial ELISA kits were used for HTLV-1 and HIV testing. Only strongly reactive specimens are reported here.

RESULTS	No.	#Pos.	%
Normal blood donors, several regions of Zimbabwe	931	1	0.1
Leukemia patients	6	0	0
Hemophiliacs (multi-transfused)	23	0	0
HIV-negative patients with symptoms from the WHO clinical AIDS criteria.	88	0	0
HIV-seropositive patients with neurologic disease	11	2	18.2) p
HIV-seronegative patients with neurologic disease	21	1	4.8).10
(of which 2 were typical TSP, both HTLV-1 neg)	1080	4	0.4

Of three patients with HTLV-1 and neurologic diseases:
1) 53 y.o. HIV-positive man with myelopathy progressing over 3 months.
2) 21 y.o. HIV-positive woman with probable zoster transverse myelitis and subsequent progression of neurologic deficit.
3) 38 y.o. HIV-negative woman with a 3 year history of spastic paraparesis. Other causes were not fully excluded in this patient.
CONCLUSIONS: HTLV-1 appears less common in Zimbabwe than other African countries. It is strongly associated with neurologic disease. Possible association with leukemia or HIV infection requires further study.

Th.A.P.2

SCREENING FOR HTLV-I ANTIBODIES AMONG FINNISH BLOOD DONORS, HEMOPHILIACS AND HIV-SUSPECTED

P. Leinikki, E. Mattila, J. Koistinen, J. Leikola, H. Brummer-Korvenkontio and M.-L. Kantanen. National Public Health Institute, and The Finnish Red Cross Blood Transfusion Service, Helsinki, Finland.

Objective. To evaluate HTLV-I screening among blood donors.

Methods. Serum samples from blood donors (N=1803), hemophiliacs (N=196), patients of health care centers (N=2761), AIDS information and support centers (N=446), i.v. drug abusers and inmates were tested using HTLV-I ELISA test (Du Pont, USA). Confirmatory tests were done by WB (Du Pont, USA), indirect immunofluorescene and passive agglutination of gelatine particles coated with viral antigen (K. Okochi, Kyuhsu University Hospital, Fukuoka, Japan).

Results. No true positive cases were found. Nine sera were repeatedly reactive in the ELISA test. None of them gave a characteristically positive reaction pattern in WB but showed reactivity against individual components of the virion. The reactive sera came from hemophiliacs (1), healthy blood donors (4), health care center patients (4) and AIDS information and support centers (1). The final result was confirmed by immunofluorescence and passive agglutination.

Conclusion. HTLV-I screening is not warranted among blood donors in Finland at the moment. The atypical reactivity, sometimes interpreted as an indication of a HTLV-I related retrovirus and earlier reported from patients with lymphomas or leukemias was also found among healthy blood donors.

Th.A.P.4

PREVALENCE OF HTLV-I ANTIBODIES IN HIV-1 INFECTED PATIENTS IN A MINORITY COMMUNITY IN THE BRONX, NY

Bauer, Stanley; Amaral, L.; and Ernst, J.
The Bronx-Lebanon Hospital Center, Bronx, NY, USA.

Objective. To determine the prevalence of HTLV-I infection in an HIV-1 infected inner-city population.
Methods. Anonymous sera (classified by age, sex, and race) and positive by HIV-1 ELISA and WB were tested by HTLV-I ELISA and WB. HIV-1 ELISA negative control sera were tested by HTLV-I ELISA. HIV-1 positive sera were from clinic outpatients, emergency room patients, and inpatients with no factors which met exclusion criteria of the CDC Sentinel Hosp. Program. HIV-1 negative sera from the hospital population served as controls.
Results

SOURCE PATIENTS	NUM HIV-1 POS	% HTLV-I POS
Sentinel Hosp.	394	28%
Clinic	58	21%
Emergency Room	24	50%
Control (HIV-1 NEG)	172	8%

Conclusion. HTLV-I infection has spread more widely in inner-city minority groups than has been previously documented.
Study partially supported by the CDC Sentinel Hospital Program.

Th.A.P.6

Th.A.P.7 HTLV-I ANTIBODIES IN THE SOLOMON ISLANDS.

*Hardy, Daniel B. *Carlson JR, *Yee JL, and **Armstrong MYK.
*University of California, Davis Medical Center, Sacramento, CA, USA and **Yale University School of Medicine, New Haven, CT, USA.

Objective. To determine the extent of HTLV-I infection in the Solomon Islands.
Methods. We tested 1,317 random individuals over the age of 5 using ELISA (Cellular Products, Buffalo, NY and Dupont, Wilmington, DE) as a screening test. We used antigen from Hillcrest Biologicals (Cypress, CA) to prepare Western Blots (WB) as a confirmatory test.
Results. The prevalence of antibody interactive with HTLV-I by ELISA was 12.6% (90/716) in the North Solomons Province (Papua New Guinea) and 14.6% (88/601) in Malaita Province (Solomon Islands). However, in the North Solomons Province sample, only 5 of 90 samples positive by ELISA were positive by WB. Thirty four were negative and 51 were indeterminate, usually showing faint p19 or p24 core bands.
Conclusion. Although there is a high prevalence of antibody interactive with HTLV-I by ELISA in the Solomon Islands, few ELISA-positive samples were also positive by WB. These puzzling results may reflect problems with HTLV-I WB testing, cross-reactivity with immune complexes, or the existence of an antigenic variant of HTLV-I or a novel retrovirus in this area of the South Pacific.

Th.A.P.9 HIV-1 AND HTLV-I SEROPREVALENCE IN CRITICALLY ILL RESUSCITATED EMERGENCY DEPARTMENT PATIENTS.

Lewandowski, C; Ognjan, A; Rivers, E; Pohlod, D; Belian, B; and Saravolatz, Louis D. Henry Ford Hospital, Detroit, Michigan, USA,

Objective. To determine the HIV-1 and HTLV-I seroprevalence and demographic features among critically ill emergency department (ED) resuscitated patients in a low HIV-1 seroprevalence area.
Methods. Patients who required resuscitation had an anonymous questionnaire completed by their physician. Sera was obtained and tested by ELISA. Repeatedly reactive samples were confirmed by IFA for HIV-1 and both Western Blot and RIPA for HTLV-I.
Results: Between 9/24/88 and 1/15/89 there were 25,378 ED visits. Patients studied reflected the demographics of a Detroit inner city hospital ED. Seventy-nine percent (257/325) of eligible candidates were enrolled with a mortality of 25.3% (65/257).

	N	HIV-I	HTLV-I
Trauma (blunt or penetrating)	144	4.9% (7/144)	1.4% (2/144)
Medical Resuscitation	113	4.4% (5/113)	2.7% (3/113)
Total	257	4.7% (12/257)	1.9% (5/257)

Intravenous drug use was determined by history in 7/17 and by physical examination in 8/17 retroviral infected patients.
Conclusion. Health Care workers in a low HIV-1 seroprevalence area are at risk for HIV-1 and HTLV-I exposure during the resuscitation of the critically ill ED patient. Identification of known high risk groups occurs in approximately one-half of patients, emphasizing the need for strict adherence to universal precautions.

Th.A.P.11 PREVALENCE OF HTLV-1 ANTIBODY IN SELECTED WOMEN IN THE LOS ANGELES AREA

Rasheed Suraiya, Norton, S. S. and Gill, P. S.
Laboratory of Viral Oncology and AIDS Research, USC School of Medicine, Los Angeles, CA U.S.A.

Objectives: To determine the seroprevalence of HTLV-1 in women with high risk behavior.
Methods: Sera were collected from women with the history of multiple male sexual partners and analyzed for HTLV-1 and HIV antibodies. Medical history and other data were obtained from the questionnaire forms completed at the time blood was drawn for testing.
Results: We have previously reported that 6% of women with multiple sexual partners were positive for antibodies to HIV (Gill, Rasheed et al, AIDS, 1986). Testing of 143 sera that were negative for HIV antibodies for the presence or absence of HTLV-1 antibodies indicated that 11 of 143 sera (7.7%), contained HTLV-1 reactive antibodies. All sera that reacted in the HTLV-1-ELISA recognized specific HTLV-1 proteins of gp46, p25, p24, p19 and p15 in the immunoblots. The ages of seropositive women ranged from 18 to 43 years and all had multiple sexual partners for several years. Physical examination did not reveal lymphadenopathy or other symptoms. Two of the HTLV-1-positive women were black, one hispanic and 8 caucasian. None of the women had a history of blood transfusion or received any blood product. Only 3 of 11 seropositive women admitted occasional use of intravenous (IV) drugs.
Conclusions: We report a high incidence of HTLV-1 infection in women with multiple sexual partners. Since only 3 of 11 women had used IV drugs, it is evident that HTLV-1 was transmitted sexuallly. Although none of the women showed any symptomatic illness at the time their blood was tested, a prospective study would be important to relate HTLV-1-infection with any disease that may develop in the future.

Th.A.P.8 LACK OF HTLV-I INFECTION IN NON-I.V. DRUG USING HIV SEROPOSITIVE MEN IN LOS ANGELES

Aboulafia, David, Mitsuyasu, R.T., Slamon, D.J.
Division of Hematology-Oncology. UCLA Department of Medicine, Los Angeles, California.

Objective. To determine the seroprevalence of HTLV-I infection among HIV seropositive males.
Method: 634 sera obtained from Western blot confirmed HIV seropositive men seen at the UCLA AIDS Center between 1984 and 1988, were subjected to radioimmunoprecipitation (RIP) using an HTLV-I infected human T-cell line (SLB-I). Sera obtained from known Japanese adult T-cell leukemia patients and noninfected healthy individuals served as positive and negative controls. Groups studied: 1) Asymptomatics (N=131), 2) AIDS Related Complex (N=115), 3) Kaposi's Sarcoma (N=300), 4) AIDS defining opportunistic infections (N=76), and 5) high grade lymphomas (N=12). Only 2 patients were known I.V. drug users.
Results. None of the tested sera were positive for antibodies to HTLV-I gene products. In contrast, using identical methods, we previously reported that 3.1% of sera collected from a prostitute cohort (N=197) in Los Angeles harbor antibodies to HTLV-I (1). Seropositive females used I.V. drugs or were found to have frequent sexual contact with I.V. drug using men.
Conclusion. By using a sensitive and specific assays that we have employed extensively in HTLV-I endemic areas, we find, in opposition to previous studies, that HTLV-I infection is uncommon among select groups of HIV seropositive homosexuals who do not engage in I.V. drug usage (2). Furthermore, no cross reactivity between HTLV-I and HIV p24 *gag* gene products was seen during RIP analysis. Additional studies looking at the seroprevalence and consequence of HTLV-I infection in broader based populations at risk for retroviral infection are in progress.
References. (1) *Blood* Vol. 72, No. 5, Suppl. 1, 1988. (2) *Virology* Vol. 150, 1986.

Th.A.P.10 HIV-1 AND HTLV-I INFECTIONS IN INTRAVENOUS DRUG USERS (IVDUS) IN DETROIT 1985-1989.

Ognjan, A.*; Markowitz, M.*; Pohlod, D.*; Lee, H.**; Belian, B.*; and Saravolatz, Louis D.*, et al. *Henry Ford Hospital, Detroit, Michigan, USA, and **Abbott Laboratories, N. Chicago, Illinois, USA.

Objective. To monitor the seroprevalence of HIV-1 and HTLV-I and examine the risk factors for infection, three surveys were conducted among Detroit IVDUs from 1985-89.
Methods. Consecutive serologically unknown IVDUs seeking medical care for conditions unrelated to HIV were eligible to participate. After informed consent an anonymous questionnaire was completed and sera obtained. Serum specimens were tested by ELISA and repeatedly reactive samples were confirmed by IFA for HIV-1 and Western Blot and RIPA for HTLV-I.
Results.

Year	N	HIV-1	HTLV-I	HIV-1 and HTLV-I	HIV-1 or HTLV-I
1985-1986	96	12.5% (12/96)	9.5% (7/74)	-	-
1987-1988	70	15.7% (11/70)	10.0% (7/70)	3.2% (2/70)	22.9% (16/70)
1988-1989	71	15.5% (11/71)	7.0% (5/71)	4.2% (3/71)	18.3% (13/71)

Seropositivity was not associated with risk reduction practices, prostitute contact, or duration of drug use. IVDUs who traveled to metropolitan New York were more likely to be HIV-1(+) than those who did not ($p<0.02$). The HTLV-I attack rate was higher in HIV-1(+) vs HIV-1(-) drug users ($p<0.05$).
Conclusion. During 1985-89, the prevalence of antibody to HIV-1 and HTLV-I has remained stable among Detroit IVDUs. Travel to an epidemic area increased the risk of acquisition of HIV-1. Since coinfection exceeded the expected frequency, HIV-1 and HTLV-I transmission may not be exclusively independent events.

Th.A.P.12 HTLV-1 INFECTION IN AN INNER-CITY EMERGENCY DEPARTMENT POPULATION

Kelen, Gabor;[a] DiGiovanna T;[a] Lofy L;[a] Sivertson K;[a] Quinn T.[a,b]
[a]Johns Hopkins University, Baltimore MD, [b]NIAID, NIH, Bethesda, MD, USA.

Objective: To study the epidemiology of HTLV-1 in a population known to have a high rate of HIV-1 infection.
Methods: Excess serum samples drawn from 2544 consecutive adult patients presenting to an inner-city emergency department in Baltimore were tested for HTLV-1 and HIV seropositivity by ELISA and confirmed by Western Blot (WB).
Results: We found 30 (1.2%) of the samples to be WB seropositive to HTLV-1. While 152 of the patients (6.0%) were WB seropositive to HIV-1, only 3 patients (all IV drug users) had concurrent infections. The age range among HTLV-1 seropositive patients was 20 to 86 years old, with half the patients greater than 50 years old. The age distribution of HTLV-1 infected individuals matched that of the patient population. In contrast, HIV was concentrated among those 25-44 years of age ($p<.05$). Of the HTLV-1 seropositive patients, 93% (28) were black, whereas blacks made up only 77% of the patient population ($p<.05$). Only 15 patients had an identified risk factor; 10 were IV drug users and 5 were transfusion recipients. One other patient's only potential known source of infection was sexual exposure to an HIV infected partner. All but one of the HTLV-1 infected patients lived in the surrounding neighborhood implying that migration from endemic areas was not likely a principal factor for infection.
Conclusion: Although the prevalence of HTLV-1 in the United States has been estimated to be .03%, HTLV-1 may be more prevalent in certain areas of the U.S. than previously thought. Sexual transmission did not seem to play a major role in HTLV-1 infection. The data support the hypothesis that HTLV-1 and HIV are relatively independently transmitted diseases.

Th.A.P.13 ANTI-HTLV-1 IN NEW YORK BLOOD DONORS (1985-1986)

Taylor, Patricia*; Stevens, C.* and Lee H.**,
*The New York Blood Center, New York, New York, U.S.A.,
**Abbott Laboratories, Chicago, Illinois, U.S.A.

Objective. To determine the prevalence of antibody to HTLV-1 in 1985-1986 donors to the Greater New York Blood Program.
Methods. Sera were screened by EIA (Abbott Laboratories, Ill.) and confirmed by Western blot and RIPA.
Results. Fourteen (0.08%) of 18,257 donors tested were confirmed anti-HTLV-1 positive. The following table shows anti-HTLV-1 prevalence by sex, ethnicity and place of birth.

Donor Characteristic		% Positive
Sex:	Male	0.06%
	Female	0.10%
Ethnicity:	White	0.03%
	Black	0.53%
	Hispanic	0.26%
Birthplace:	U.S.A./Canada	0.04%
	Caribbean	1.54%
	Other	0.00%

One anti-HTLV-1 positive donor was anti-HBc positive.
Conclusions. Only one unit of blood from the 14 anti-HTLV-1 positive donors would have been excluded from the donor pool by other routine screening methods (anti-HBc testing). Ethnicity and birthplace appear to be associated with the risk of HTLV-1 infection.

Th.A.P.14 DETERMINANTS OF HTLV-I SEROPREVALENCE IN MIYAZAKI PREFECTURE, JAPAN.

Sherri Oliver Stuver*, H. Tachibana**, F. Romano***, N. Mueller.
*Harvard School of Public Health, Boston, MA, USA; **Miyazaki Medical School, Miyazaki City, Miyazaki, Japan; ***Institute Di Igiene E Medicina Preventiva, Universita Degli Studi Di Napoli, Napoli, Italy.

Objective: To evaluate the determinants of prevalence of antibody positivity to HTLV-I in Miyazaki Prefecture, Japan.
Methods: Data from 7055 persons who came to Miyazaki City Health Promotion Center from 9/83 to 12/84 for a free government-sponsored health exam was collected. A cross-sectional analysis was conducted to examine the relationship between seropositivity for HTLV-I (by indirect immunofluorescence assay) and such demographic factors as age, sex, area of residence, socioeconomic status (SES), and occupation. Prevalence rates were calculated, standardized for age and sex as appropriate.
Results: Seroprevalence rates for Miyazaki were 9.1% for women and 7.3% for men. Rates varied dramatically according to municipality of residence, ranging from 4.5% to 17.6% in those areas with at least 100 people participating. The prefecture could be divided into two regions based upon prevalence of infection: 1)high prevalence: the southern-most area known to be highly endemic for HTLV-I, and the adjacent inland section, bordering upon Kagoshima (12.1%); 2)medium prevalence: the remaining areas of Miyazaki Prefecture (6.6%). An inverse relationship appears to exist between prevalence of positivity and SES (as indicated by occupation) in the medium prevalence area (high SES-1.7%; middle-7.5%; low-12.6%); such a gradient is not evident for the high prevalence area (high SES-14.1%; middle-12.1%; low-18.4%). No significant association with a specific occupation is apparent.
Conclusion: Prevalence of antibody positivity to HTLV-I in Miyazaki Prefecture, Japan, seems to be primarily a function of age, sex, area of residence, and, in lower endemic areas, SES.

Th.A.P.15 SEROPREVALENCE OF HTLV-1 IN A PARTURIENT POPULATION AT RISK FOR HIV-1 INFECTION.

Krasinski, Keith; Borkowsky, W; Fidelia, A; Bebenroth, D; Moore, T. New York University Medical Center – Bellevue Hospital Center, New York, New York, U.S.A.

Objective. To determine the seroprevalence of HTLV-1 in a parturient population at risk for HIV-1 infection.
Methods. Cord bloods from consecutive deliveries at Bellevue Hospital Center were tested for antibodies to HIV-1. Positives and a sample of negatives were tested for HTLV-1. Each antibody was assayed with commercially available ELISA.
Results. Of 3883 cord bloods, 142 (3.65%) had anti-HIV-1. Of the 142, 16 (11.3%) had anti-HTLV-1. No anti-HTLV-1 was detected among the first 163 HIV-1 seronegative cord bloods. Of those with antibodies to both viruses, strong HTLV-1 and HIV-1 ELISA signals were present in 12/16. Weak HIV signals and strong HTLV-1 signals were present in 4, including: 2 with weak HIV p24 bands only on Western Blot analysis, and 2 with indeterminate HIV-1 Western blots.
Conclusion. HTLV-1 is more common among HIV-1 infected parturient women than HIV-1 seronegative women. This may reflect the similar mechanisms of transmission or may be the result of patient demographics and the geographic origin of parturient women at risk for HIV-1. HTLV-1's contribution to disease in HIV-1 infected mothers, and its transmission and contribution to disease in their children remains to be determined. The presence of antibody to HTLV-1 cross reacting with HIV-1 may explain some low positive or equivocal HIV-1 serologic results.

Th.A.P.16 SEROPREVALENCE OF HTLV-I IN PATIENTS ATTENDING SEXUALLY TRANSMITTED DISEASES (STD) CLINICS IN THE UNITED STATES.

Khabbaz, Rima*; Douglas, J.**; Spiegel, R.*; St Louis, M.*; Whittington, W.* and Lairmore, M.*. *CDC, Atlanta, Ga, **Denver Disease Control, Denver, Colorado, U.S.A.

Objective. To assess the seroprevalence of HTLV-I in patients attending STD clinics. Methods. Sera from 1860 STD clinic patients were tested for HTLV-I antibodies by EIA; reactive sera were confirmed by WB and RIPA. 1275 on whom no information on intravenous drug use (IVDU) was available were from clinics in the southeast (SE): Atlanta, GA; Nashville, TN; Birmingham and Mobile, AL; Greenville and Columbia, SC; Raleigh and Whiteville, NC. 585 patients were from Denver, CO, and comprised 384 with and 201 without histories of IVDU. Results. Of 1275 STD clinics patients in the SE, only 2 (0.15%, 95% CI 0.04-0.63%) were positive (antibodies to p24 and env gene product); 13 (1%) had indeterminate HTLV-I reactivities (bands on WB but not meeting criteria for positivity). The 2 seropositive patients were black women from Atlanta; the seroprevalence of HTLV-I in the SE was therefore 2/826 (0.24%) for blacks compared with 0/328 (0%) for whites (p=NS). Among Denver IVDU patients the seroprevalence of HTLV-I was 8/384 (2%) compared with 0/201 (0%) in non-IVDU (p=.03, 1-tailed Fisher); in IVDU patients, the HTLV-I rate was higher in blacks ,2/47 (4.3%), than in hispanics, 1/56 (1.9%), or whites, 3/170 (1.8%, p=NS). Conclusion. Our results show that the seroprevalence of HTLV-I is low in STD clinic patients and confirm that IVDU is the major risk factor for HTLV-I in the U.S.. The prevalence of HTLV-I in STD clinic patients in the SE seems lower than suspected from earlier reports.

Th.A.P.17 RISK OF DEVELOPMENT OF HTLV-I-ASSOCIATED MYELOPATHY (HAM/TSP) AMONG PERSONS INFECTED WITH HTLV-I

Osame,M.*; Kaplan, Jonathan**; Igata,A.*; Kubota,H.*; Nishitani,H.***; Janssen,R.**. *Kagoshima University, Kagoshima, Japan; **Centers for Disease Control, Atlanta, Georgia; ***Utano National Sanitorium Hospital, Kyoto, Japan.

Objective. To determine the yearly and cumulative risk of development of HAM among persons infected with HTLV-I. Methods. National surveys of HAM were conducted in Japan in 1987 and 1988. A "definite" case of HAM was defined as a patient with slowly progressive myelopathy and antibodies to HTLV-I in both serum and CSF. Estimates of seroprevalence of HTLV-I in 8 HTLV-I-endemic prefectures (seroprevalence >3%), by age group, were obtained from studies of blood donors; the 1986 population, by prefecture and age group, was obtained from the census. Results. Of 589 definite cases of HAM reported nationally, 393 occurred in residents of the 8 endemic prefectures included in this analysis; of these, 170 reported onset of illness during the years 1982-1988, for an average incidence of 24.3 cases/year. Using the seroprevalence estimates and 1986 census figures, we estimated the number of HTLV-I-seropositive persons in the 8 prefectures in 1986 at 611,700. We therefore estimated the incidence of HAM among HTLV-I-infected persons at 4.0×10^{-5} cases/year; given a lifetime of 70 years, the lifetime incidence is approximately 1/4 of 1%. Adding 38 "probable" cases of HAM reported from the 8 prefectures with onset in 1982-1988 increased this estimate to only 1/3 of 1%. Conclusion. The risk of development of HAM in the lifetime of an HTLV-I-infected person is estimated at <1%. This estimate is important in counseling persons, such as blood donors, found to be infected with HTLV-I.

Th.A.P.18 HTLV-I/II SEROPREVALENCE AND HIV/HTLV COINFECTION AMONG IV DRUG ABUSERS (DA) IN THE U.S.

Kenneth P. Cantor*;Weiss,S.H.**;Goedert,J.*; and Battjes,R.***. *US Ntnl Cancer Inst,Bethesda,MD,**NJ Medical School,Newark,NJ,***US Ntnl Inst on Drug Abuse,Rockville,MD,USA.

Objective. To determine seroprevalence of HTLV-I/II and HIV/HTLV coinfection among IV DA in 6 US locations and to assess the influence of age, sex, and race on seroprevalence and coinfection.
Methods. Data were collected from 1,766 IV DA in a continuing cross-sectional survey of drug treatment admissions. HIV was confirmed by Western blot (WB). HTLV-I/II Ab presence was defined by a + response in at least 2 of 3 assays: Dupont EIA, P-24 RIA, and WB.

Results.	(n/%)	HIV+	HIV(?)	HTLV+	HTLV(?)	BOTH+
Blacks	(n=576)	190/33.0%	2	110/19.1%	31	41/7.1%
Hisp.	(n=586)	118/20.1%	2	50/ 8.5%	26	3/0.5%
Whites	(n=604)	62/10.3%	1	29/ 4.8%	12	1/0.2%
TOTAL	(n=1766)	370/21.0%	5	189/10.7%	69	45/2.5%

HTLV-I/II prevalence increased significantly with age among blacks (from 0% in <30 yrs to 35% in 40+) and non-blacks (from 2.8% in <30 yrs to 13.8% in 40+). HTLV prevalence was similar by sex and varied geographically from 0% to 18%. HIV/HTLV coinfection in blacks was 7.1% (6.3% expected,NS) but 0.4% in non-blacks (1.2%expected,NS).
Conclusion. High prevalence of HTLV-I/II infection was found among blacks and older DA. HTLV prevalence among blacks was generally above that in whites and Hispanic DA. Coinfection rates, when examined by age, ethnicity, and geography, failed to confirm a significant interaction between HIV and HTLV-I/II seropositivity.

Th.A.P.19

HTLV-1 AND HIV-1 INFECTION IN INTRAVENOUS DRUG ABUSERS OF BARCELONA.

Tor Jordi, Soriano V, Muga R, Ribera A, Clotet V, Foz M.
Infectious Diseases Unit and Blood Bank Unit, Hospital de Badalona "Germans Trias i Pujol", Universitat Autònoma de Barcelona, Barcelona, Spain.

Objective. To evaluate the prevalence of HTLV-1 infection among intravenous drug abusers (IDAs) in an area were a high incidence of HIV-1 infection has been described previously in this risk group.

Methods. IDAs seeking medical care for the first time between January 1985 and December 1988 in our hospital, were tested by Elisa for the presence of anti-HIV-1 and anti-HTLV-1 antibodies. Western blot was used as confirmatory test in repeatedly reactive samples.

Results. During the study period, 473 IDAs serum samples were screened and the overall HIV-1 and HTLV-1 antibody prevalence was 70.0% and 0.6 %, respectively. The seroprevalence rates were stable during the study period. Coinfection was detected in all cases with HTLV-1 antibodies.

Conclusion. IDAs in our area represents an important reservoir for HIV-1 infection , but our data pointed to a low prevalence of HTLV-1 antibodies. For both retroviruses the total figures did not change throughout the four-year period.

Th.A.P.21

HIGH RATE OF CONFIRMED HTLV II INFECTION AMONG INTRAVENOUS DRUG ABUSERS (IVDA) FROM NEW ORLEANS

Lee, Helen*; Swanson, P.*; Shorty, V.**; Zack, J.***; Rosenblatt, J.***; and Chen, I.*** *Abbott Laboratories, N. Chicago, IL; **Desire Narcotics Rehabilitation Center, New Orleans; LA ***UCLA School of Medicine, Los Angeles, CA,U.S.A.

OBJECTIVE. Determination of HTLV I/II infection in New Orleans IVDA.
METHODS. (1) Serum from 121 IVDA were tested by EIA, Western blot and RIPA for antibodies to HTLV I/II. (2) Lymphocytes from 27 of 121 IVDA were analyzed by PCR. HTLV I/II sequences were differentiated via restriction and sequence analysis. (3) Viral cocultures were done using lymphocytes from 9 EIA positive IVDA and 20 negative EIA low risk individuals. Reverse transcriptase (RT) and immunofluorescence (IF) with monoclonal anti-p24 and anti-p40X were used to monitor viral expression.
RESULTS. (1) Serum samples from 54 of 121 IVDA were EIA positive, 33 of which were confirmed by Western blot and/or RIPA.

(2) EIA	WESTERN BLOT/RIPA	PCR: HTLV I +	HTLV II +	NEGATIVE
23 Positive IVDA	18 Confirmed	2	16	0
	4 Indeterminate	0	3	1
	1 Negative	0	1	0
4 Negative IVDA	4 Negative	0	1	3
20 Negative Donors	20 Negative	0	0	20

(3)All 9 cocultures of EIA and IVDA lymphocytes were positive by IF. At 6 weeks of culture, 8 of the 9 cocultures were also positive by RT.
CONCLUSION.A cohort of 21 HTLV II positive individuals has been identified in New Orleans. This represents the largest HTLV II cluster confirmed by a combination of virological and molecular genetic methods.

Th.A.P.23

COINFECTION WITH HIV, HTLV-1 AND HBV IN TRINIDAD AND TOBAGO

Courtenay Bartholomew*, F. Cleghorn**, B. Hull**, K.Battoo**, C. Diaz**, W. Blattner***.
*The University of the West Indies;
** The Caribbean Epidemiology Centre, Port of Spain, Trinidad;
*** The National Cancer Institute, Maryland, U.S.A.

425 consecutive HIV antibody positive sera assayed in 1986-88 were tested for antibodies to HTLV-1 by ELISA and confirmed by Western Blot. 43 (10.1%) were HTLV-1 antibody positive. IVDA is not practised in Trinidad and Tobago and when adjusted for age this cohort had a 5 times higher seroprevalence than the general population. 17/160(10.6%) of HIV antibody positive homosexual men were coinfected with HTLV-1, 9/90 (10%) of heterosexual women, while 14/58 heterosexual men (24.1%) were HTLV-1 antibody positive. Of 382 patients singly infected with HIV, 205 (53.7%) had AIDS or developed AIDS in the period 1986-88 compared with 28/43 (65%) of coinfected patients.

The hepatitis virus (HBV) closely resembles retroviruses in its molecular structure including a reverse transcriptase mechanism in its replication. HBV DNA has been found in T-lymphocytes of HBV infected people who are core and surface antibody positive and surface antigen negative. Significantly, out of 425 HIV positive patients, 7/8 (87.5%) who had triple antibodies to HIV, HTLV-1 and HBV had AIDS in the period under study. In a prospective study of 34 homosexual men who were singly infected with HIV and followed for a period of 5 years up to 1989, 7 (22.6%) have progressed to AIDS, while of 6 men who were doubly infected with HIV/HTLV-1, 3 (50%) have progressed to AIDS in the same time interval. Notably, of these 3 cases, 2 were HBsAg positive. Further studies are in progress to assess the role of HTLV-1 and HBV as co-factors in AIDS.

Th.A.P.20

HTLV I ANTIBODIES AMONG PRISON INMATES IN MARYLAND

Vlahov, David*; Taylor, E.*; Wisniewski, C.**; Tanner, C.*; Mehaffey, W.**; and Lee, H.** *Johns Hopkins School of Hygiene and Public Health, Baltimore, MD, USA **Abbott Laboratories, North Chicago, IL, USA

OBJECTIVE. To identify prevalence and risk groups for HTLV I infection among inmates entering prison.
METHODS. Specimens routinely obtained during intake evaluation of 1,000 consecutive male inmates, excluding repeat offenders, entering Maryland prisons during the same time period in 1987 and 1988 were assayed for antibodies to HTLV I by EIA. Repeat reactive samples were confirmed by Western blot and RIPA. Demographics were compared by serostatus using non-parametric statistics.
RESULTS. Among 1933 inmates, 19 (1%) were repeatably reactive by EIA.

GROUPS		NUMBER	N/(%) REPEATABLY REACTIVE	p VALUE
RACE:	Black	1356	19/(1.4%)	< 0.001
	Non Black	577	0/(0.0%)	
AGE:	> 25	1070	18/(1.7%)	< 0.001
	≤ 25	863	1/(0.1%)	
YEAR:	1987	900	5/(0.6%)	
	1988	1033	14/(1.4%)	0.08

Reactivity to HTLV I did not vary significantly by HIV-1 serostatus, jurisdiction, offense category.
CONCLUSION. Unlike HIV infection in this population (7.0%), approximately 1% was infected with HTLV I, occuring mostly in blacks over 25 years of age. The seroprevalence rate of HTLV I in prison inmates is 5-10 times hicher than in normal U.S. populations.

Th.A.P.22

HTLV-1 INFECTION IN SPAIN

Soriano V.*Abella E. Tor J.*Flores A. Clotet B.*Ribera A.
Infectious Diseases Unit and Service of Haematology*.
Hospital de Badalona "Germans Trias i Pujol".Barcelona.Spain.

Objective. To evaluate the prevalence of antibodies against HTLV-1 among people at risk for this viral infection.

Patients and methods. We studied serum samples of 682 intravenous drug abusers (IDAs), 53 leukaemic polytransfussed patients, 3 subjects diagnosed of Tropical Spastic Paraparesis (TSPP) and 102 West Africans living in Barcelona since 1983.
Antibodies to HTLV-1 were investigated by ELISA and repeatedly reactive samples were studied by Western blot.

Results. See table.

	IDAs	Polytransfussed	TSPP	West Africans
*ELISA + (35/840)	27/682	3/53	0	5/102
**WESTERN BLOT+	2/27	0	0	1/ 5

*ELISA Clonatec, France; **WESTERN BLOT Du Pont, USA

Conclusion. Our results suggest that HTLV-1 infection is present in Spain among IDAs and West African inmigrants. A low prevalence is recognised.

Th.A.P.24

HTLV-I IN INTRAVENOUS DRUG ADDICTS (IVDA) AND GAY MEN IN SAN FRANCISCO.

Feigal, Ellen G.*; Murphy, E.*; Drummond, J.**; Bacchetti, P.*; Chaisson, R. ***; Greenspan, J.S.****; et al., *San Francisco General Hospital, University of California at San Francisco, San Francisco, CA;**Product Research Inc.,Bethesda;***Johns Hopkins University, Baltimore MD;****School of Dentistry, University of California at San Francisco, San Francisco, CA, U.S.A.

Objective:To describe the seroprevalence of HTLV-I in IVDAs and gay men in San Francisco comparing a commercially available ELISA with Western Blot (WB) with C91 PL purified virus.
Methods:Serum samples from 909 IVDAs in methadone programs and from 353 gay men were independently blindly tested for HTLV-I in 2 independent laboratories. Most specimens were from cross-sectional participant samples between 1985 and 1987. Additionally, longitudinal paired specimens were available in 153 IVDA participants.
Results:WB and ELISA showed similar temporal trends although the WB consistently detected more positives: 1985 12% ELISA +, 16% WB +; 1987 17.5% ELISA +, 19% WB +. By ELISA and WB: seroprevalence correlated with age: 0% age <20 , 8.2% age 21-30, 13.7% age 31-40, 25.9% age 41-50, 37.3% age 50 and over. Whites had fewer positive results, 10.2%, vs. 23.7% blacks, and 19.6% hispanics. Men (17.5%) were more often positive than women (14.7%). The longitudinal paired samples demonstrate reproducibility of results over time. By ELISA 21 initial positives and 116 initial negatives remained so, however 8 other initial positives were later negative and 8 other initial negatives became positive. By WB 25 initial positives and 92 initial negatives remained so. 4 positives became negative and 2 negatives became positive on follow-up sera. Many of the discrepant results observed between WB and ELISA were categorized as borderline by WB and at the borderline qualitative value of the ELISA.
Conclusions: For the study populations the two methods provided comparable results: the prevalence of HTLV-I in IVDAs in San Francisco is more common than HIV, particularly in older blacks and hispanics. Further evaluation of discrepant results is in progress with WB with HUT102 and radioimmunoprecipitation.

Th.A.P.25 COUNSELING AND FOLLOW-UP FOR INDIVIDUALS POSITIVE FOR HTLV-I ANTIBODY

Dosik, Harvey, Kohen, M., Williams, L., Hershman, E., Silberman, E., Goldstein, M.
Interfaith Medical Center, Brooklyn, NY, U.S.A.

Objective: Black adults from Central Brooklyn were screened for HTLV-I antibody because of the large number of patients with Adult T-Cell Leukemia Lymphoma found in this community. Therefore a protocol had to be developed for follow-up and counseling for antibody positive persons.
Methods: This study was performed as a community project by Primary Care Internal Medicine residents and volunteers. Of 484 individuals screened thus thus far, 15(3.17%) were found to be positive for HTLV-I antibody. Each antibody positive person receives a telephone contact from a resident, a complete history and physical exam, a request for blood samples for HTLV-I antibody retesting, cellular testing and HIV testing and counseling.
Results: A patient information sheet was developed which consists of 3 simply worded paragraphs on health implications of HTLV-I infection and transmission of the HTLV-I virus. Additional materials were prepared for resident-counselors. The protocol takes one hour to conduct with 15 minutes alloted for HTLV-I counseling.
Conclusion: Thus far, all patients have responded favorably to the protocol. State mandated protocols for counseling are not available for HTLV-I as they are for HIV, however, CDC has recently issued guidelines. Since testing programs may lead to the detection of significant numbers of HTLV-I antibody positive individuals, counseling programs such as this one will prove to be necessary.

Th.A.P.27 PREVALENCE OF HTLV-I IN GREEK BLOOD DONORS

A DERIVIANAKI [1], E MALLIARAKI-PINETIDOU [2], Y GEORGOULIAS [1,2]
1. Tumor Cell Biology Laboratory, School of Medicine, University of Crete
2. AIDS Reference Center of Crete, Venizelion Hospital, Crete, Greece

Objectives: To determine the prevalence of HTLV-I in a highly touristic region of Greece
Methods: Sera from 820 blood donors, and 129 heterosexuals comming to the AIDS Reference Center for HIV-1 infection study were tested by an HTLV-I EIA and repeatedly positive sera were confirmed by Western blot analysis
Results: Seven blood donors and 3 heterosexuals were revealed positive by the ELISA test. The values ranged berween 1.5-3 times the cut off. Repeately positive were 4 blood donors and the 3 heterosuxuals
Western blot revealed antibodies against the p19, p24, p36 and gp46 in 2 blood donors and 1 heterosexual whereas in 2 other heterosexuals only antibodies against the p36 and gp46 were detected. All subjects were clinically normal. The overall prevelence of HTLV-I infection in the district of Iraklion seems to be 0.24% and 0.77% in the blood donors and heterosexuals, respectively
Conclusion: The above findings indicate the presence of HTLV-I infection in the population of Crete suggesting that additional attention should be necessary for blood tranfusions

Th.A.P.29 INVESTIGATIONS ON THE PRESENCE OF HTLV-1 INFECTION IN INTRAVENOUS DRUG ABUSERS AND HOMOSEXUALS IN THE FEDERAL REPUBLIC OF GERMANY

Ehm, I.; Pauli, G.; Thiele, B.; Karbowiak, B.; Beck, Andreas; Koch, M. A.
AIDS-Zentrum, Bundesgesundheitsamt, Berlin, Federal Republic of Germany

The human T-cell lymphotropic virus type 1 (HTLV-1), which causes a specific form of adult T-cell leukemia and the tropical spastic paraparesis, is endemic in some areas of Africa, the Caribbean and southwestern Japan.

Antibodies against HTLV-1 were also detected in intravenous drug abusers (IVDA) in the United States, Great Britain, Italy and the Netherlands.

Because transmission of HTLV-1 occurs probably by the same route as HIV, HTLV-1 antibodies might be first detectable in the HIV high risk groups (IVDA, homosexuals).

No HTLV-1 infection could be detected in sera from West German IVDA in the years 1986 and 1987.

We investigated now sera of 354 IVDA (104 HIV-1 positive) and 526 homosexuals (97 HIV-1 positive) collected in the year 1988 on HTLV-1 antibodies by ELISA, Western blot and immunofluorescence. HTLV-1 antigen was harvested from culture fluid of MT-2 cells.

14 out of 880 sera tested, reacted positive in the ELISA. None of the ELISA-positive results could be corroborated neither in the Western Blot nor in the immunofluorescence. To clarify wether hemophiliacs might be infected by HTLV-1 we are testing sera from these patients for the presence of antibodies against HTLV-1.

Th.A.P.26 SEROPREVALENCE OF HTLV-I ANTIBODY IN A BLACK BROOKLYN COMMUNITY

Dosik, Harvey*; Williams, L*; Goldstein, M*; Silberman, E*; Levine, P**; Maloof, R.**
*Interfaith Medical Center, Brooklyn, New York, **Environmental Epidemiology Branch, National Cancer Institute, Bethesda, MD, U.S.A.

Objective: Because 16 of 86 cases of Adult T-Cell Leukemia/Lymphoma reported to the American ATL Registry were diagnosed in Blacks from Central Brooklyn, N.Y., a study was conducted to determine the prevalence of HTLV-I antibody in this population.
Methods: Sera were obtained from study subjects attending outpatient Clinics or community health fairs. Two assays were performed to determine antibody positivity. Together they have a high specificity but a low sensitivity.
Results: 15/484 (3.17%) of sera were positive on both assays. This represents a minimum HTLV-I prevalence in the study subjects. The male to female ratio among positive subjects was 3:12; it was 138:298 among negatives. The mean age for positive subjects was 51.8±17.8; it was 54.5±16.3 for negatives. The overall antibody positivity rate was significantly different (p .0001) from that found in all U.S. blood donors (10/39,898) Science 240:643-6,1988)
Conclusion: Additional HTLV-I antibody prevalence studies should be done on non-blood donor populations to determine groups at higher risk for HTLV-I infection.

Th.A.P.28 SEROPREVALENCE OF HTLV-I AMONG U.S. MARINES STATIONED IN A HYPERENDEMIC AREA

Brodine, Stephanie K.*; Oldfield, E.C.*; Corwin, A.L.**; Thomas, R.J.***; Ryan, A.B.**; Holmberg, J.+; Molgaard, C.A.++; Golbeck, A.L.++; Ryden, L.A.++; Benenson, A.S.++; Blattner, W.A.+++.
*Inf. Dis. Div. Nav. Hosp., San Diego, CA, U.S.A., **3rd MARDIV, Okinawa, Japan, ***NEPMU-6, HI, U.S.A., +PACOM, Nav. Hosp., Okinawa, Japan, ++San Diego State University, San Diego, CA, U.S.A., +++NCI, Bethesda, MD, U.S.A.

Objective. To determine the seroprevalence of HTLV-I in American military personnel stationed in a hyperendemic area-Okinawa, Japan.
Methods. U.S. Marines assigned on Okinawa, Japan in a 'permanent' tour (1-3 years) were accessioned by unit-primarily by company. Each participant completed a consent form, an intake questionnaire, and 15 cc of blood was obtained. HTLV-I serologies were performed at the NCI Retrovirology Lab, Fort Detrick, and Biotech Laboratories, Rockville, MD.
Results. Between April and July 1988, 5,267 personnel were tested. 30 personnel (5.7 per thousand) were repeatedly reactive by ELISA. Confirmatory assays are in progress and include Western Blot, Radioimmune Precipitation Assay (RIPA), Recombinant ELISA to envelope protein, and Polymerase Chain Reaction (PCR) Assay. 18 of these 30 specimens have been tested by Western Blot-2 are positive with both p19 and p24 bands present and 7 have an indeterminate band pattern (6 with p19 and 1 with p24 only). Follow-up serologies will be done on those with an indeterminate pattern. The two individuals who are positive are male, caucasion, not from the Southeastern U.S., and were stationed in Okinawa for at least 6 months prior to the testing.
Conclusion. There is a markedly lower seroprevalence rate among U.S. military personnel on-island as opposed to the ~18% seropositivity rate found in the general population of Okinawans. Further epidemiologic analysis will be presented. Supported by U.S. Army R&D Command.

Th.A.P.30 COINFECTIONS HIV1/HTLV1 EN MARTINIQUE

C. Moisson-Vernant*, M. Monplaisir*, R. Chout**, C. Sobesky*, R. [illegible]***, D. Calès-Quist**, *CHRU Fort-de-France;
**Dispensaire MST Fort-de-France; ***Inspecteur de la santé, Fort- de-France, Martinique.

Objectifs : La Martinique, zone d'endémie pour le HTVL1 (2,2 % des donneurs de sang pos.) a été atteinte par l'épidémie HIV1 (0,28 % des donneurs de sang, 4,5 % des consultants du Dispensaire MST et 8,7 % des patients hospitalisés, HIV 1 pos.). Il nous a donc paru intéressant de rechercher les sujets doublement infectés et d'étudier l'éventuelle influence du HTLV1 sur l'infection HIV1.
Méthodes : 256 HIV1 positifs ont été testés en anticorps anti HTLV1 (Elisa et Western Blot).
Résultats : 33 sujets ont été retrouvés doublement positifs, soit 12,9 %.
Provenance : Dispensaire MST : 18 % des patients HIV1+ sont doublement infectés (7 prostituées positives sur 14). Donneurs de sang : 2,6 %, patients hospitaliers : 8,4 % des sujets testés.
Age : Les co-infectés sont en moyenne plus agés que les monoinfectés.
Sexe : 18 % des femmes, 8,5 % des hommes sont doublement infectés. Il y a prédominance féminine comme dans les autres groupes de HTLV1 positifs (donneurs de sang, HAP, anguilluloses ...).
Facteurs de risque : Aucun des 18 héroinomanes HIV+ n'est HTLV1 positif. Chez les hommes homo ou hétérosexuels, la prévalence est la même (10 %). Par contre, dans la population féminine, la prévalence est nettement supérieure chez les prostituées (30 % / 15 %).
Caractéristiques cliniques et biologiques : Aucun des doubles infectés n'a développé de HAP ou d'ATL. Au point de vue clinique et biologique, il ne semble pas y avoir d'interférence notable du HTLV1 sur le HIV1. L'isolement des souches virales et la PCR ont été pratiqués chez certains.
Conclusion : Dans cette étude préliminaire, le virus HTLV1 ne parait pas influer sur les caractéristiques de l'infection HIV. Une étude du suivi évolutif des patients sur une longue période est en cours, ainsi qu'une étude plus particulière de la population des prostituées.

Th.A.P.31 SEROLOGICAL CONFIRMATION OF HTLV-I INFECTION IN BLOOD DONORS

Anderson, David*; Lee,TH**; Lairmore,M***; Saxinger,C+; Kalyanaraman,VS++; Slamon,D+++; Parks,W++++; et al.
*FDA,Bethesda,MD, **Harvard,Boston,MA, ***CDC,Atlanta,GA, +NCI,Bethesda,MD ++Bionetics,Rockville,MD, +++UCLA,Los Angeles,CA, ++++U. Miami, Miami,FL USA.

Objective. Develop criteria for serological confirmation of HTLV-I infection.
Methods. 4 Western blots (WB) and 4 radioimmunoprecipitation (RIP) assays were used to study sera from 38 Japanese, 69 American and 35 Caribbean blood or plasma donors. All sera were reactive on HTLV-I ELISA or gel-agglutination assays with at least one viral-specific band on WB. Specific antibodies were called positive if detected by a majority of tests as follows: p19: ≥2/4 WB, p24: ≥4/8 WB or RIP, $p40^x$: 1/1 RIP, gp46 or gp61 (gp46/61): ≥3/6 WB+RIP.
Results. WB was more sensitive for p24 antibodies while RIP was more sensitive for gp46/61 antibodies (Ab). 135 sera had both p24 and gp46/61 Ab and of these, 128 sera had p19 Ab. 108 sera had $p40^x$ Ab; all 108 sera also had gp46/61 Ab.

Numbers of Donor Sera:	Reactive to gp46/61	Nonreactive to gp46/61
Reactive to p19 + p24	128 (100 had $p40^x$ Ab)	2 (0 had $p40^x$ Ab)
Reactive to p24 only	7 (7 had $p40^x$ Ab)	1 (0 had $p40^x$ Ab)
Reactive to p19 only	1 (1 had $p40^x$ Ab)	3 (0 had $p40^x$ Ab)

Virologic evidence of infection was found in 7 American donors by lymphocyte co-culture (1 HTLV-I, 1 HTLV-II) or by polymerase chain reaction (3 HTLV-I, 2 HTLV-II). Sera from all 7 donors showed p24 and gp46/61 Ab. 6 sera had $p40^x$ Ab (3 HTLV-I, 3 HTLV-II) and 3 sera had p19 Ab (2 HTLV-I, 1 HTLV-II). Thus, seroreactivity patterns to p19, p24, $p40^x$ and gp46/61 did not consistently distinguish donors with HTLV-I from those with HTLV-II infection.
Conclusions. Seroreactivity to both p24 and gp46/61 by WB and/or RIP are suitable criteria to confirm but not distinguish HTLV-I and HTLV-II infections.

Th.A.P.32 ANTIBODY TO HTLV I/II AMONG BLOOD DONORS IN FOUR CITIES OF THE UNITED STATES

Transfusion Safety Study Group* represented by Mosley, James W.**.
*Participating institutions in New York City, Miami, Detroit, Seattle, San Francisco, and Los Angeles, USA, **University of Southern California School of Medicine, Los Angeles, California, USA.

Objective. To identify anti-HTLV-I/II (+) donations in the TSS/NHLBI Donor Repository, in order to characterize donors with HTLV-I/II infection and observe the consequences of transfusion among their recipients.
Methods. The TSS/NHLBI Donor Repository has 200,000 donor sera collected in late 1984 and early 1985, just before routine anti-HIV-1 testing. Screening for anti-HTLV-I/II is complete for South Florida, and is in progress under a uniform protocol in New York, San Francisco, and Los Angeles.
Results. South Florida had 23 donors with confirmed positivity among 29,931 donations tested (0.8/1,000); thus far, 11 donors and 6 recipients have been enrolled. Interim data for the other 3 areas are as follows:

Area	Total donations	Tested (10/21/88)	Repeatably reactive Number	Repeatably reactive /1,000	Fully confirmed Number	Fully confirmed /1,000	RR/ conf.
New York	74,128	19,500	38	2.0	18	0.9	.47
San Francisco	25,832	20,600	26	1.3	8	0.4	.31
Los Angeles	66,884	18,200	32	1.8	20	1.1	.62

Conclusion. Anti-HTLV-I/II results to date suggest that 150 to 200 donors will be identified for tracing, and that 75 to 100 of these donors and 40 to 60 of their recipients will be enrolled.

(Supported by Contracts No. N01-HB-4-7002 and N01-HB-4-7003 of the National Heart, Lung, and Blood Institute.)

Th.A.P.33 RECALL BIAS AND MEMORY FAILURE: AN EMPIRIC DEMONSTRATION IN PERSONS WITH ACQUIRED IMMUNE DEFICIENCY SYNDROME

Grimon, Karen*; Schechter MT*; Sheps SB*; Hershler R*; Craib KJP*.
*St. Paul's Hospital and the University of British Columbia, Vancouver, BC, Canada.

Objective. To determine the presence of systematic error in the recall of risk factors by persons with AIDS.
Methods. Questionnaire responses regarding sexual practices, drug use, and STD's during 1978-82 were compared in 2 groups of gay men. Group 1 consisted of members of an ongoing prospective study (The Vancouver Lymphadenopathy-AIDS Study) who subsequently developed AIDS. Group 1 was interviewed in 1983 when none had AIDS nor even knew their serologic status. Group 2 consisted of persons diagnosed with AIDS between 09/86 and 01/88 at St. Paul's Hospital. All Group 2 subjects had already been diagnosed when interviewed. Both groups were diagnosed in the same hospital by the same specialists. This hospital sees over 75% of all cases in the province.
Results. Group 1 consisted of 58 men who were interviewed a median of 3.3 years prior to diagnosis. Group 2 consisted of 74 men interviewed a median of 4 months following diagnosis. There were no differences between the groups with regard to age, ethnicity, annual income, or AIDS manifestation. For responses concerning the period 1978-82, Group 2 was significantly less likely to report gonorrhea, non-specific urethritis, and venereal warts. Group 2 also reported fewer sexual contacts in bathhouses and clubs. Conversely, Group 2 reported greater frequencies of oral-genital contact, oral-anal contact, and anal intercourse but lower frequencies of fisting. Group 2 were more likely to report initiation of regular sexual contact prior to age 20.
Conclusion. These data invite 3 explanations. The differences could be due to (i) true differences due to selection biases; (ii) memory failure in Group 2 due to the elapsed time and/or to the CNS effects of the disease; or (iii) recall bias influencing attribution of risk by Group 2. We feel that the curious pattern of the inconsistencies is most compatible with recall bias, although any of the 3 explanations has clear implications for those conducting retrospective research in AIDS.

Th.A.P.34 HIV-TESTS OR -TESTEES?

Valle Sirkka-Liisa * and Sarna S. **.
* University Central Hospital, Helsinki, Finland,
** University of Helsinki, Finland.

Objective. To demonstrate the difficulty in estimating the number of testees from the total number of HIV-antibody tests performed.
Methods. We collected the patient charts of all persons who had seen a private dermato-venereologist who is specialized in HIV infection, for imagined or real HIV-related problems in 1984-1988. We calculated both the annual number of HIV-tests requested by the practitioner herself, and the number of HIV-tests performed elsewhere (health care centers, hospitals, AIDS Support Centers etc). The age and sexual preference of the patient were recorded and in case of heterosexual men, a possible mention of having visited a prostitute was noted.
Results. A total of 988 HIV-tests had been performed on 468 individuals during Sept.1984 through Dec.1988 (2.1 tests per person on average). 187 homosexual men, 152 heterosexual men and 129 heterosexual women were seen. 34.8% of the heterosexual men had visited a prostitute. 175 persons (37.4%) had taken one or more tests elsewhere before seeing the practitioner and a total of 453 tests had been made. 535 tests were requested by the practitioner. There was a clear change both in the number and sexual preference category of the persons tested during the 4-year-period.
Conclusion. This study demonstrates that an error of 53% (1-468/988) was caused by multiple testing. Although this material might be biased towards multiple testing, caution is recommended when prevalence figures are calculated by using the number of tests instead of testees as denominator.

Th.A.P.35 CALCULATING HIV INCIDENCE RATES FROM SEROPREVALENCE DATA

Sokal, David*; Shelton, B.**; Kupper, L.***.
*Family Health International, Research Triangle Park, North Carolina, U.S.A., **University of North Carolina, Chapel Hill, North Carolina, U.S.A., ***University of North Carolina, Chapel Hill, North Carolina, U.S.A.

Objective. Develop a method to estimate annual incidence rates of HIV infection based on seroprevalence data in order to evaluate the success of control programs.
Method. If one assumes that (a) once seropositive, people remain seropositive; (b) deaths between ages 15 to 25 are negligible compared to the number of people infected in this age group; and (c) the incidence rate of new infections is stable over time and over age, then one can estimate the incidence rate based on age specific prevalence data for the 15 to 25 year age group. Additional methods may be presented in order to overcome some of the limitations of the assumptions.
Results. A multiple of the slope of the regression line of prevalence by year of age gives an estimate of the incidence rate of new HIV infections among young individuals.
Conclusion. Improved analysis of age-specific seroprevalence data can provide a means of estimating the HIV incidence rate, and thus changes in this rate. This method provides an alternative to cohort studies in looking at the incidence rate of new HIV infections.

Th.A.P.36 SIGNIFICANCE OF MEAN AGE OF ANTI-HIV-POSITIVE PERSONS IDENTIFIED IN TEST PROGRAMS

Frösner, Gert G.
Max von Pettenkofer-Institut, University of Munich, Munich, Federal Republic of Germany

Objective. Estimation of mean incubation time of AIDS and incidence of HIV-infection.
Results. Mean age of reported anti-HIV-positve persons 15-59 years of age was 33.6 years for 13872 males and 28.8 for 2888 females (Habermehl and Maxeiner: 15th report for 12/31/88), and 38.4 for 2494 male and 32.9 for 161 female registered AIDS-patients of the same age group. The age difference between test-positives and AIDS-patients (4.8 and 4.0, respectively) defines a minimum for mean incubationn time of AIDS. However, mean incubation time seems to be considerably longer because 62.87 % of test-positives already had HIV-related diseases.
Mean age of individuals between 15-59 years was 32.54 for 10404 persons found positive up to 9/30/87 and 33.16 for 7183 persons found positive later (difference in mean testing time 22 months). Without new HIV-infections since the first testing period, mean age of anti-HIV-positive individual should have increased by 22 months. The only 7.44 months increase in mean age suggests that about two third of anti-HIV-positive persons of the second test period only recently had been infected.
Conclusion: Mean incubation time of AIDS is well above 4 years. Monitoring mean age of anti-HIV-positives may give information on incidence of HIV-infection and on efficacy of prevention.

Th.A.P.37 SAMPLE SIZES FOR NEEDLES IN A HAYSTACK: THE CASE OF HIV SEROPREVALENCE SURVEYS IN CANADA

Frank, John;Coates, R.;Garbutt, J.;Brant, R. Department of Preventive Medicine and Biostatistics, University of Toronto, Toronto, Canada.

The authors present an approach to sample size calculations for anonymous HIV seroprevalence studies base upon a novel nomogram. The nomogram summarizes formal power calculations for the Poisson distribution over a range of expected seroprevalence rates and various "deltas". Deltas are expressed as a minimum percentage increase in the expected seroprevalence which is felt to be worthy of detection or, conversely, imperative to "rule out", at specified alpha and beta error levels. In the case of a proposed neonatal heelprick seroprevalence study, use of the nomogram leads to some interesting results. At the expected seroprevalence for women bearing children (10/100000), testing the entire year's birth cohort of 135,000, could be expected to identify <15 seropositive infants with resultant Poisson 95% confidence interval ranging from 5.5 to 16.8/100000. On the other hand, a sample of only 30000 neonatal heelprick specimens/year would greatly reduce survey costs (by $300,000) but would identify only 3 seropositives with 95% confidence intervals of 2 to 29/100000. As a compromise, we have used the nomogram to establish a sample size of 80000, sufficiently large to provide a power of 0.8 (alpha=0.05, 1-sided) to detect a doubling or more of the expected seroprevalence rate. This strategy results in a projected survey cost, and 95% confidence interval width which are both mid-way between those of the other two sample sizes options. The implications for HIV seroprevalence surveys in jurisdictions with even lower expected HIV seroprevalence rates or smaller populations will be discussed.

Th.A.P.38 VOLUNTARY HIV STUDIES CAN UNDERESTIMATE SEROPREVALENCE

Rekart, Michael L. STD Control, Ministry of Health, Vancouver, British Columbia, Canada.

Objective To compare the HIV risk and seroprevalence in females voluntarily participating in an anonymous HIV study with a comparable group not participating.

Methods Over a 13 month period, every third woman attending the Vancouver VD Clinic was asked to participate in a multicentre Canadian study of HIV risk and seroprevalence. A total of 468 women agreed to participate and 283 refused. An additional 19 women volunteered for the study. In the nationwide study 2,184 women agreed to participate. During the same 13 month period in the Vancouver VD Clinic, 691 women were tested outside the study. This latter group was made up of women refusing to participate and women not recruited. These groups are compared.

Results All three groups were comparable in age and risk behaviours. The seroprevalence in participating Vancouver women was 0/487; for the nationwide study there was only 1 positive in 2,184 participants; in the 691 women tested in Vancouver outside the study there were 5 positive tests (0.7%). The difference between the two Vancouver groups is significant to p = .069; the difference between the nationwide study participants and the Vancouver non-participants is significant to p = .004.

Conclusion HIV studies which rely on voluntary participation can underestimate the actual seroprevalence in the target population. Such a selection bias can result in a falsely optimistic view of the epidemic and negatively influence resource allocation and control.

Th.A.P.39 RESEARCH OR SURVEILLANCE? ANONYMOUS SEROPREVALENCE STUDIES: THE QUEBEC EXPERIENCE

Hankins, Catherine*; Lapointe, N.**; Laberge, C.***; Roy, D.****; Elmslie, K.*****; Gendron, S.*.

*DSC-Hôpital général de Montréal & McGill University, **Hôpital Ste-Justine & Université de Montréal, ***Réseau de Médecine génétique du Québec, Québec, ****Institut de Recherches Cliniques, Montréal, *****Federal Centre for AIDS, Ottawa, Canada.

Objective: To examine the feasibility of conducting an anonymous unlinked seroprevalence survey using newborn heelprick filter paper specimens as peer-reviewed research as opposed to mandated surveillance.

Methods: Constraints to implementation included epidemiological issues such as stratification, completeness of demographic variables, and potential for bias. Organisational concerns were storage, transport, duplicate specimens, and use of Hepatitis B immune globulin containing anti-HIV. Technical issues were micro-ELISA and micro-BLOT test performance and transfer of technology. Ethical issues included consent, right to know, safeguards for anonymity, and potential harm. Expert ethical and legal consultation was integral to the exploration of feasibility.

Results: The Canadian context necessitated a research orientation to the important ethical issues posed by this epidemiological methodology. A public relations plan was designed to inform the populations concerned: pregnant women, parents of newborns, physicians and the general population.

Conclusion: Depending on the cultural context, the planning of anonymous seroprevalence studies should consider whether a research or a surveillance orientation is appropriate.

Th.A.P.40 EVALUATION OF DRIED BLOOD FILTER PAPER SAMPLES, COLLECTED BY FINGER STICK AS AN ALTERNATIVE TO VENIPUNCTURE FOR HIV SEROPREVALENCE SURVEYS IN HIGH RISK ADULTS

Sheppard, Haynes.*; Wiley, J.**; Ascher, M.***. *California Public Health Foundation, Berkeley, CA; **Survey Research Center, Berkeley, CA; ***Viral and Rickettsial Disease Lab, Department of Health Services, Berkeley, CA,USA.

Objective. To evaluate the use of finger stick collection methods and compare the results of serologic testing of dried blood filter paper samples with serum samples collected by venipuncture.

Methods. Blood specimens were collected by venipuncture and on filter paper by finger stick from 120 men, of known serostatus, in the San Francisco Men's Health Study. HIV ELISA tests were performed with matched filter paper and serum samples and the ratio of optical density of specimen to negative control was determined.

Results. Estimated as distance from the cutoff (t test), HIV serologic tests using filter paper had slightly lower sensitivity (97.5 vs 99.9) and slightly better specificity (99.9 vs 99.5). In addition there was good correlation between the O.D. ratios of filter paper and serum samples from seropositives (R = 0.799). In most cases three or four 1/2 inch blood spots could be collected from a single finger stick. This provides sufficient specimen to perform a minimum of 16 ELISA and 8 Western blot determinations.

Conclusion. Finger stick collection, storage, and shipping of dried blood on filter paper is simple, cost effective, and provides adequate specimen for storage and repeated testing. For the purpose of seroprevalence, the accuracy of HIV serologic tests are not significantly compromised by this collection method. This methodology may be useful as a substitute for venipuncture in seroprevalence surveys.

Th.A.P.41 DESIGNING OBSERVATIONAL STUDIES AND FIELD TRIALS OF TREATMENTS AND PREVENTIONS AGAINST HIV INFECTION AND AIDS

Halloran, Mary E*; and Struchiner, Claudio J.**; Robins, JM*

*Harvard School of Public Health, Boston, Mass., USA;
**Instituto do Medicina, Universidade Estado do Rio de Janeiro, Brazil.

Objective: To delineate designs of observational studies and field trials of treatments and preventions against HIV infection and AIDS taking into account the direct and indirect effects of interventions in infectious diseases, that is, the dependent happening structure of events.

Methods: Three study designs are defined based on the groups of comparison. Study Design I compares the group with the intervention with the group not receiving intervention where the two are subjected to the same transmission intensity. Study Design II compares the group with intervention to another separate group not receiving intervention. Study design III compares the overall population in which some receive intervention with a separate population, either geographically or temporally separate, without intervention.

Results: Study Design I is adequate for studying effects at an individual level, however gives no overall measure of public health benefits. Study Design II yields a measure of effect on the individual plus the effect of changing transmission. Study Design III yields a measure of overall public health benefit of an entire intervention. Study Design I using usual incidence based estimators breaks down when non-incidence based interventions are employed.

Conclusions: Study Designs II and III need to be developed further for interventions against AIDS to be adequately assessed. Non-incidence based estimators of intervention effects will help avoid some of the methodological difficulties in infectious disease epidemiology.

Th.A.P.42 VALIDATION OF SEXUAL HISTORIES OF HOMOSEXUAL MALE COUPLES

Seage III, George R.*; Mayer, KH.**; Horsburgh, CR.***; Cai, B.*; Lamb, GA.*.

*Boston Department of Health & Hospitals, ** Fenway Community Health Center, Boston, MA., *** Centers for Disease Control, Atlanta, GA. USA.

Objective. To determine the validity of self-reported mutual sexual practices within male homosexual relationships by comparing independent reports from each member of a couple.

Methods. To date, 248 couples consisting of 468 individuals have been enrolled in the study. Thus far, 136 (55%) pairs were separately interviewed about their sexual practices with each other. Spearman correlation coefficients were used to assess levels of agreement. To assess whether this varied with other independent factors, a multiple regression model was developed with the index's response as the dependent variable, and partner's response, HIV diagnosis and status, number of sexual partners, and sequence of study visit as independent variables.

Results. Significant agreement between indexes and partners were observed for the total number of exposures (r=.93,p<.0001), number of anal exposures (r=.75,p<.0001), number of oral exposures (r=.71,p<.0001), and condom use (r=.85,p<.0001). Regression analysis of responses revealed the tendency for indexes, who tended to be sicker, to report greater numbers of encounters than partners. Significant levels of agreement between index and partner was observed for all sexual activities. No other independent variable was significant in the models.

Conclusion. These results indicate that histories of sexual behaviors within a relationship can be confirmed and therefore may be reasonably valid.

Th.A.P.43

STATISTICAL CONSIDERATIONS OF MISCLASSIFICATION OF PATIENTS AT BASELINE IN TWO AIDS CLINICAL TRIALS

Alan B. Forsythe*; Elashoff, J.D.** and Dixon, W.J.**
*Viratek, Inc., Costa Mesa, California, USA/UCLA School of Medicine, Los Angeles, California, USA, **The Dixon Group, Los Angeles, California, USA.

Objective. To estimate the impact of initial patient classification in 2 studies of oral ribavirin.
Methods. Data from LAS (N=164) and ARC (N=215) patient groups were combined after a statistical reclassification of patients. The reclassification was based on covariates measured at the time of enrollment in such a way as to define 2 new groups of patients maximizing the within strata homogeneity at baseline. This analysis examined the effects of possible misclassification of patients among the LAS and ARC trials. Statistical adjustment for prognostic variables was done on a Cox proportional hazards model. Sensitivity analysis to evaluate model assumptions and protocol restriction were performed to supplement the primary analysis.
Results. The data when stratified by original study designation, statistically restratified by baseline characteristics or treated as 1 large group all yield statistically significant ribavirin effect in delaying the progression to AIDS. The hazard rate of progressing to AIDS is cut in half.
Conclusion. Initial patient classification is not an important contributor to the conclusion that ribavirin was effective in delaying progression to AIDS among these patients.

Infection par le VIH chez les travailleurs de la santé
HIV Infection among Health Care Workers

Th.A.P.44

GUIDELINES FOR PREVENTION OF TRANSMISSION OF HUMAN IMMUNODEFICIENCY VIRUS AND HEPATITIS B VIRUS TO HEALTH-CARE AND PUBLIC SAFETY WORKERS

Mullan RJ, Baker Edward L, Scally MJ, Strine PW
National Institute for Occupational Safety and Health
Centers for Disease Control
Atlanta, Georgia, U.S.A.

In response to recently enacted United States legislation (Public Law 100-607, The Health Omnibus Programs Extension Act of 1988, "AIDS Amendments of 1988"), guidelines have been developed for all health-care and public safety workers (including emergency medical workers, fire fighters, police, and correctional facility workers) in the United States.

The document provides an overview of the modes of occupational transmission of HIV and hepatitis B virus (HBV), an assessment of the risk of transmission under various assumptions, principles underlying the control of risk, and specific risk control recommendations for employers and workers. Also included in this document is information relating to medical management of persons who have sustained an occupational exposure to these viruses. A separate model curriculum based on the principles and practices discussed in this document has been developed concurrently for use in training workers.

An overview of the guidelines and curriculum will be presented, with specific recommendations for preventing transmission of these bloodborne viruses to emergency medical service workers, fire fighters, police, and correctional facility officers.

Th.A.P.45

ZIDOVUDINE PROPHYLAXIS FOR PERSONS WITH ACCIDENTAL PERCUTANEOUS BLOOD EXPOSURE: A DECISION ANALYSIS

Rose, David N; Sacks, HS; Mount Sinai School of Medicine, New York, NY. U.S.A.

Objective. We performed a decision analysis to determine the thresholds of safety and effectiveness which would justify short-term zidovudine (AZT) administration for persons with accidental percutaneous exposure to either HIV-positive blood or blood of unknown HIV-serologic status.
Methods. We used a Markov model to accommodate the short-term risks of HIV infection and AZT effectiveness and toxicity and the long-term risks of AIDS development and mortality. The outcomes studied were life expectancy and lives saved per cohort. Published data were used to estimate seroconversion rate (0.42%), rate of HIV-infected developing AIDS (5%/year), and AIDS survival (50%/year). No information is available on AZT effectiveness and little is known about AZT irreversible toxicity. Wide variations in all assumptions were made in the sensitivity analysis.
Results. For those with exposure to blood known to be HIV seropositive, the benefits of AZT outweigh the risks under all but a combination of the most skeptical assumptions of AZT safety and effectiveness. Using moderate assumptions (AZT effectiveness 50%, safety 2 deaths per 30,000 AZT recipients), AZT use extends life expectancy by 3 weeks and averts 174 deaths per 100,000 persons exposed. Under more optimistic assumptions (90% effectiveness and 1 AZT death per 30,000), life expectancy is extended by 6 weeks and 322 deaths are averted per 100,000. However, under pessimistic assumptions (5% effectiveness and 8 AZT deaths per 30,000), the risks of AZT minimally outweigh the benefits. Wide variations in the assumptions have little effect on the thresholds, with the exception of the likelihood of seroconversion after exposure: If the blood serologic status is unknown, the likelihood of seroconversion is a function of the local prevalence of HIV infection; the AZT benefits do not clearly outweigh the risks when the prevalence is below 10-20%.
Conclusions. Until the results of clinical trials are known, the decision must be based on strength of belief regarding AZT effectiveness and toxicity. Unless studies show AZT to be both highly ineffective and toxic, the benefits of short-term AZT outweigh risks after exposure to HIV-positive blood. AZT benefits do not clearly outweigh risks after exposure to blood of unknown serologic status.

Th.A.P.46

NATIONAL SURVEILLANCE PROGRAM: OCCUPATIONAL EXPOSURE TO HUMAN IMMUNODEFICIENCY VIRUS (HIV-1) INFECTION IN CANADA

Elmslie, Kimberly; Mulligan, L; O'Shaughnessy, M. Federal Centre for AIDS, Health Protection Branch, Ottawa, Ontario, Canada.

Objective: To assess the risk of HIV infection among health-care workers (HCWs) exposed to blood or body fluids from an HIV-infected person.
Methods: Eligibility criteria require a documented parenteral, mucous membrane, or skin contact exposure to blood or body fluids from an HIV-infected person. HCWs are followed for one year post-exposure. Blood specimens are taken at 6 week intervals for six months post-exposure and at 9 and 12 months. Standard information collected include demographics, risk factors and exposure circumstances.
Results: As of January 6, 1989, 234 HCWs had enrolled in the study. 85% of these were health-care providers, 11% laboratory technicians and 4% other workers. 47% of exposures were needlestick, 4% scalpel wounds, 12% eyespash, 16% open-wound contaminations, and 21% skin contact. 90 (39%) of the 234 exposures were likely preventable, had standard infection control procedures been used. Excluding HCWs for whom a baseline serology (within 30 days of exposure) was not available, there have been no seroconversions among the remaining 175 study participants.
Conclusions: These data are consistent with other studies and support a very low risk of transmission of HIV infection resulting from parenteral, mucous membrane, or non-intact skin exposures in the occupational setting.

Th.A.P.47

BLOOD EXPOSURES DURING SURGICAL PROCEDURES.

Panlilio, Adelisa*; Perlino, C.**; Parrish, C.**; Foy, D.**; Lowry, P.*; Bell, D.* *Centers for Disease Control, Atlanta, Georgia, USA; **Grady Memorial Hospital, Atlanta, Georgia, USA.

Objective. To describe the nature and frequency of occupational exposure to blood among operating room (OR) personnel during surgical procedures in a large public hospital.
Methods. Trained observers sampled operations and recorded the type and duration of procedure, emergency nature, estimated blood loss by the patient, occupations of personnel, infection control precautions used, and number and type of exposures.
Results. One or more persons had skin, mucous membrane, or parenteral exposures to blood during 49 (33%) of 151 operations, including 9/19 (47%) in trauma, 12/32 (38%) in orthopedic, 12/39 (31%) in gynecology, 8/35 (23%) in general surgery, 3/19 (16%) in plastic surgery, and 5/7 (71%) in burn procedures. Of 1350 personnel observed, 84 (6.2%) experienced 116 blood exposures, including 49 contacts with exposed skin (42%), 40 episodes of clothing soakage (35%), 13 exposures due to possibly defective gloves (11%), 10 needlesticks or cuts with sharp objects (9%), and 4 eyesplashes (3%). Risk factors for exposure (relative risk; 95% confidence interval) included being a surgeon (3.8; 2.5-5.8), participating in an emergency procedure (3.4; 2.2-5.1), patient blood loss > 250 ml (3.6; 2.5-5.4), and duration of time in OR > 1 hour (5.3; 2.9-9.8).
Conclusion. The risk of blood exposure for operating room personnel is substantial. Studies are needed to quantitate this risk, identify risk factors for exposures, determine the risk of HIV infection due to these exposures, and to design and evaluate preventive measures.

Th.A.P.48

REPORT OF A POSSIBLE LABORATORY ACQUIRED HIV INFECTION.

Haley, Charles E*, Reff VJ*, Murphy FK**.
*Dallas County Health Dept; **UTx Southwestern Med Ctr, Dallas, Texas, USA.

Objective: Case report of possible occupationally acquired AIDS.
Case Report: In 1987, a 28 year old woman was referred to evaluate for a possible HIV infection. She had donated blood in 6/85 and was HIV negative, but a donation in 5/86 was HIV positive. She was ELISA and western blot positive, but asymptomatic until 6/88 when she developed pneumocystis pneumonia. On interview, she claimed two lifetime sexual contacts: one, before 1981, who was not tested, but thought to be healthy in 1987; and a current partner, who had no serologic evidence for HIV infection in 6/87. The woman was a technologist who worked in a clinical laboratory that was known to handle HIV positive specimens. She denied other risks including transfusions, drug abuse, and other sexual contacts. She experienced a scratch from a blood contaminated needle in 9/84 and admits to occasionally contaminating her hands with blood. She washed her hands frequently and was being treated for severe atopic dermatitis of her hands. An examination found no abnormalities except keratosis and weeping fissures on her palms.
Conclusion: No discrete exposure was found in the interval between the blood donations. This woman possibly became infected by direct inoculation of the weeping lesions on her hands with HIV contaminated blood in the laboratory.

Th.A.P.49 THE RISK OF EXPOSURE TO HUMAN IMMUNODEFICIENCY VIRUS AMONG HEALTH CARE WORKERS (HCW) AT A SOUTHERN U.S. URBAN HOSPITAL.

Risi, George*; Gaumer, R*; Weeks, S.*; Leete, J.;**, Sanders, C.*
*Louisiana State University Medical Center, New Orleans La., USA, **Abbott Laboratories, North Chicago, IL, USA.

Objective. To assess the risk of exposure to HIV among HCW's at an Urban Hospital in the Southern United States (Charity Hospital of New Orleans).
Methods. Plasma remaining from CBC analysis of a cohort of patients presenting to the acute medical (n=246), the acute surgical (n=67) and obstetrical unit (n=221) were subjected to ELISA screening for HIV, with confirmation by Western Blot. Demographic information obtained on all patients included age, race, sex, zip code, risk factors for HIV, and type of problem. All HCW interventions with the possibility of exposure to blood or body fluids were recorded. All patient identifiers were removed.
Results. Of 534 specimens, 11 (2.1%) were positive overall (9 men and 2 women). Rates were similar among black and white patients. Seven patients could be placed into a known risk group after interview, but only one was known to be at risk prior to some HCW intervention. None of the obstetrical patients was seropositive. Five point nine percent of trauma patients and 2.9% of medical patients were seropositive. Among men, there were similar rates of seropositivity among several age groups. At least two procedures with the potential to transmit HIV were performed per patient.
Conclusion. A substantial risk of exposure to HIV exists in the trauma and medical emergency areas. Thus, all HCW's in this region need to practice universal barrier precautions.

Mathematical Modelling and Prediction

Th.A.P.50 CENSUS DATA AND FORECASTING U. S. AIDS CASES

Pickering, John; Robbin, J.E.; Lieb, L.E.; Rutherford, G.W.; Woodbury, M.E.; van de Laar, M.J.W.; et al.
Department of Entomology, University of Georgia, Athens, GA, U.S.A.

AIDS cases are unevenly distributed geographically. Nearly half of U. S. cases have been reported by New York and California that have less than 1/5th of the total U. S. population. Within California, over 2/3rds of cases have been reported by Los Angeles and San Francisco counties that have only 1/3rd of California's total population.

Long-term epidemic forecasts should consider local differences in population size, life-style and onset of transmission. The Public-Use Microdata Samples of the U. S. census provide data on demographic and life-style variables. The A-Sample is a 5% sample of the U. S. population. It has information on age, sex, marital status and relationship of individuals within households in 1154 areas that together make up the United States. Based on these data, we have estimated the relative size of populations at-risk to AIDS through homosexual transmission.

Using the population estimates, local AIDS incidence data, and an epidemic model, we forecast AIDS incidence from the local through national level. Although sensitive to parameter values and our assumptions, these forecasts give insight into the geographic distribution of AIDS. For example, while the incidence data of AIDS in San Francisco and Los Angeles have been similar to date, we project that there will be ultimately 2-4 times more cases in Los Angeles than San Francisco.

Th.A.P.51 BEHAVIORALLY BASED MODELING OF THE SPREAD OF HIV

Brown, Tim. University of Hawaii at Manoa, Honolulu, Hawaii, USA.

Objective. Describe a new approach to computer modeling of HIV and other sexually transmitted disease spread in heterogenous populations.
Methods. A sample of individuals closely matching the demographic and risk behavioral characteristics of a population is generated by computer and all HIV transmitting activities are simulated using distributed discrete event simulation techniques. Due to the computational intensity of this approach, these simulations are executed on parallel computers, machines with more than one processor. The result is a computerized laboratory for the evaluation of geographic, demographic, and behavioral factors.
Results. Early implementations have been completed on a Symult Systems 2010 multicomputer, with more sophisticated versions in preparation. A description of the program components and input requirements is given; preliminary experiments with the models and their use in modeling HIV spread in Hawaii and Thailand are described.
Conclusions. Behavioral simulation provides a means of incorporating both geographical and demographic factors and the effects of behavioral intervention efforts into the modeling of HIV propagation.

Th.A.P.52 A DYNAMIC MODEL OF HIV TRANSMISSION AND AIDS IN SAN FRANCISCO

Hethcote, Herbert W., University of Iowa, Iowa City, IA, U.S.A.

Objective. To forecast HIV prevalence and AIDS incidence in the homosexual population in San Francisco using a transmission dynamics model.
Methods. The compartments in the model are susceptibles and stages in the phases: HIV incubation, asymptomatic, pre–AIDS, AIDS and death. The homosexual population is also subdivided into the active and very active sexual categories with immigration, emigration and transfer between categories. The computer simulation model is a system of nonlinear difference equations with a time step of one month. The fit criteria require that the model be consistent with the a priori parameter estimates, with the reporting delay–adjusted AIDS incidence from 1980 to 1987 and with the estimated HIV prevalence from 1978 to 1987. Projections are made assuming that decreases in sexual activity continue and also assuming no changes in sexual behavior after 1987.
Results. The pattern in the simulation model is that the HIV prevalence peaked at about 20,000 in 1985 (out of 56,000 homosexuals in San Francisco) and that the yearly AIDS incidence peaks at about 1500 in 1989 and decreases to less than 1000 by 1995. Although there is some saturation in the very active group, adequate fits are not obtained without changes in behavior. In the simulation the average number of new partners per month decreases by a factor of about 0.6 each year from 1982 to 1987.
Conclusion. The distribution of the AIDS incubation period with 7 stages gives the best fit in the simulation model. The simulations predict that the AIDS incidence peaked in 1989 and will decrease in the future. This pattern is primarily due to changes in behavior.

Th.A.P.53 HIV Carriers: Increasing Infectivity with Progression to AIDS has Important Implications for the AIDS Epidemic among Heterosexuals.

Gonzalez, Jose J.*; Moe, C.E.**; Davidsen, P.*** and Koch, M.G.****.
*ASA, N-4800 Arendal, **ADH, N-4601 Kristiansand, ***Univ. Bergen, N-5000 Bergen, Norway, ****VåC, S-546 00 Karlsborg, Sweden.

Recent evidence suggests that the degree of infectiousness increases with the duration and progress of the HIV infection. We have developed mathematical models taking into account increasing infectivity along with progression to AIDS, heterogeneous sexual behavior, import and export of persons and infections, and variable patterns of infectiousness.

The duration of both the seroconversion latency state and the interval of slight infectivity associated with it probably depends on the method of transmission and the infective dose. If this is so, then heterosexual HIV transmission is likely to be followed by a relatively long latency period, which in turn suggests that the rate currently observed for heterosexual transmission of the HIV will probably change accordingly. With the passage of time, new HIV carriers will necessarily enter the stages of increased infectiousness and thus accelerate the further spread of the HIV in a predictable way.

Th.A.P.54 A MULTIPLE RISK GROUP MODEL TO ESTIMATE AND PROJECT THE SPREAD OF HIV

Philip C. Cooley*; Christopher, S.*; Hamill, D.* and van der Horst, C.**
*Research Triangle Institute, Research Triangle Park;
**University of North Carolina at Chapel Hill, Chapel Hill, N.C., USA.

Objective. To describe an HIV transmission model and results of the model.
Methods. The model exhibits the following characteristics:

- all major (sexual and nonsexual) transmission routes are included.
- different transmission routes are accommodated simultaneously.
- parameters that are difficult to estimate (e.g., number and types of sexual or needle sharing contacts) are endogenous to the model, and
- results from the model can be used to evaluate intervention strategies.

The essential model features are described in four sections: estimation of initial population sizes, the algebraic representation of the dynamics of HIV, estimation of within and between risk group infection rates, and projection of the spread of HIV.
Results. National U.S. data is used to estimate model parameters and to provide 10-year projections of the course of the HIV and AIDS epidemics.

Th.A.P.55 HIV DYNAM..CS IN LINKED RISK GROUPS, A MULTIGROUP TRANSMISSION MODEL

Hans (J).A.M.van Druten*, J.C.Jager**, M.J.J.C.Poos**, R.A.Coutinho***, E.J.Ruitenberg
*University Nijmegen (MSA), The Netherlands; **National Institute of Public Health and Environmental Protection (RIVM), Bilthoven; ***Municipal Health Service, Amsterdam, The Netherlands.

The HIV/AIDS epidemic is a composite of many overlapping and linked epidemics in several risk groups, each with its own dynamics and time course. The simultaneous spread of the infection is described by a multigroup transmission model. Six risk groups are distinguished: the homo/bisexual community (two levels of promiscuity), the intravenous drug users (men and women), and the promiscuous heterosexual men and women. Three modes of transmission are considered: anal and vaginal intercourse and needle sharing. Two matrices - a transmission and dynamic size matrix - are defined to connect the high dimensional parameter space with the HIV incidence in the 6 risk groups. The model helps to clarify which data are needed to disentangle the relative contribution of the within and between group transmission routes. Given a specification of a baseline, the potential use of the model is illustrated by simulations describing effects of: a) blocking the transmission between the main risk groups and b) blocking the transmission due to needle sharing. The results suggest that the homo/bisexual epidemic runs its own course and that blocking the transmission between the main risk groups may substantially reduce the spread into the heterosexual population.

Th.A.P.57 IMPACT OF SEXUAL BEHAVIOUR CHANGE ON THE AIDS EPIDEMIC

Blythe, Steve.
Strathclyde University, Glasgow, Scotland.

Objective. To investigate the effects of changes in sexual behaviour on HIV transmission and the AIDS epidemic.
Methods. A new modelling technique is developed that permits the fast numerical solution of a HIV transmission model with multiple sexual activity levels, where the mean and variance of the number of partners per year is imposed as an arbitrary function of time. Using this, the timing and magnitude of an epidemic can be investigated under different patterns of sexual activity change.
Results. The details of the timing and magnitude of behaviour change (reducing the number of sexual partners each individual will on average take) dictate its value as a control measure. Although an early change is better than a later one of the same magnitude, eradication requires prolonged reduction and long-term low levels, if the disease is not to re-appear in a second epidemic.
Conclusion. Observed behaviour changes in certain sections of the community may be sufficient to cause HIV to die out locally, but unless change is made on a large scale, and on a lasting basis, further epidemics could occur.

Th.A.P.59 THE POTENTIAL FOR SPREAD OF HIV IN THE HETEROSEXUAL POPULATION IN NORWAY,A SIMULATION MODEL STUDY

Hein Stigum, J K Grønnesby, P Magnus,J M Sundet, L Bakketeig
Dep. of Epidemiology, National Institute of Public Health. Norway.

Objective
To assess the potential for spread of HIV in the heterosexual population in Norway, based on sexual behavioral data, with and without input of infection from other groups.
Method
A simulation model is used. The model population is the heterosexual population (excluding IV-drug users) in Norway aged 18 to 60 years. The population is divided by age, sex and marital status. In each group the number of HIV infected subjects is calculated based on group specific values for: the frequency of intercourse, the partner turnover, the pattern of partner choice, the proportion of married/cohabiting subjects eligible as extra marital partners, prevalence of infection and transmission probability. The transmission probability and the AIDS hazard rate varies with time since infection. Behavioral data is taken from the Norwegian study on sexual habits. (random sample = 10.000, response rate 63% (J M Sundet, this conference)).
Results
The epidemic is not selfsustained in the heterosexual population when the average transmission probability is below 1% per intercourse, and there is no input of infection from other groups.
This result is insensitive towards changes in the initial conditions. It is sensitive towards changes in sexual behavior and in particular towards changes in the form of the transmission probability distribution. The simulated number of discordant couples is compared with empirical studies indicating that 1% transmission is too high. When input of infection from other groups is considered, the prevalence level is found to depend both on the influx of infection, and on the distribution of the contacts with the heterosexual population. Different source groups with different flux and contact distributions are discussed.
Conclusion
With current behavior the Norwegian heterosexual population is not likely to sustain the HIV-epidemic in isolation. Import of infection will be important in determining the prevalence level.

Th.A.P.56 ENHANCED COMPUTER MODEL OF HIV TRANSMISSION VIA NEEDLE SHARING

Ahlgren David J*; Stein A C*; Lewis B F**
* Trinity College, Hartford, CT; ** Spectrum House Inc., Westboro MA U.S.A.

Objectives: To: 1) develop quantitative descriptions of intervention measures for needle users; 2) incorporate these descriptions in a model simulating HIV transmission on the street and in jail; 3) evaluate effects of increased short- and long-term treatment center capacity and rehabilitation success rate; 4) evaluate effects of entry/exit testing to/from jail; 5) evaluate needle cleaning in jail. Parameters are to be estimated from survey data describing needle use in Worcester, MA.
Methods: Descriptions of the intervention measures are added to a preliminary model presented at the IV International Conference on AIDS. Parameters are estimated based on 1) survey data collected in treatment centers by the Worcester AIDS Consortium (2672 subjects); and 2) entry testing data for 450 inmates. We create scenarios describing 1) improved drug treatment; and 2) increased testing and needle-cleaning, especially in jails.
Results: We establish a base run simulation which matches observed seroprevalence during 1982-89. For 1989 and beyond the base run assumes moderately high rates (30%/year) of both testing for HIV antibodies and adoption of clean needles by persons found seropositive. Relative to this base run, interventions begun in 1989 provide the following reductions in the cumulative number of AIDS cases through the year 2004: 1) doubled short- and long-term treatment center capacity and rehabilitation success rate--10%; 2) 100% testing and 100% needle cleaning by persons found seropositive--5%; 3) 100% needle cleaning in jails--22%; 4) combination of 2) and 3) above--26%.
Conclusion: Combined intervention approaches can significantly reduce the number of projected AIDS cases in a population currently 18% seropositive. Simulation confirms that jails are reservoirs of HIV. To supplement aggressive testing and needle cleaning programs, provision of bleach in jails may be the most effective single intervention.

Th.A.P.58 MODELLING OF IMMUNE SYSTEM DYNAMICS IN HIV PATHOGENESIS: ISSUES IN IMMUNOMODULATION.

Rupert E.D. Whitaker, Boston University/Tufts New England Medical Center Hospitals, Boston, MA, USA.

Objective: To describe a modelling approach to the pathogenesis of HIV infection and the effects of immuno-modulatory factors (e.g., stress, drug abuse, pharmacotherapy) on the dynamics of infection and the development of disease.
Methods: STELLA for the Apple Macintosh - system dynamics modelling software.
Results: System dynamics (SD) modelling exemplifies a flexible approach to understanding the pathogenesis of HIV infection, using a complex, non-linear, multi-loop, feedback simulation of the immune response to retroviral infection. The approach shows itself to be of value in generating and testing causal hypotheses of pathogenesis and the effects of policy intervention based on the model's premisses, even in the absence of precise data. It focuses on immune response dynamics as a consequence of the structure of the immune system rather than of the one-way effects of extraneous variables (such as HIV infection) and allows a more sophisticated approach to understanding the role of immunomodulation and 'co-factors' in the development and prevention of disease.
Conclusions: System dynamics modelling of HIV pathogenesis affords a more thorough approach to understanding the essential deficits in disease development and may be useful for developing policy in the implementation of therapeutic immunomodulators and antivirals. The use of non-linear approaches to understanding pathogenesis are necessary for effective intervention development.

Th.A.P.60 EVIDENCE FOR A 16-18 YEAR MEAN TIME BETWEEN HIV VIRAL INFECTION AND AIDS ONSET.

Greatbatch,Wilson*; and Holmes W.**
* State University of New York at Buffalo;
** State University College at Buffalo, Buffalo,NY, U.S.A.

Past estimates of incubation time of AIDS have relied on estimates of time-of-infection that may have been questionable. We present 1075 cases of transfusion-related AIDS, as reported to The Communicable Disease Centers, Atlanta GA, USA, (CDC) which we have examined for the pattern between HIV viral infection and AIDS onset. This is probably the only class of AIDS patients for whom the precise time of infection is reasonably ascertainable. It is concluded that a Weibull distribution with a mean time of 18 years and a shape factor of B=2.3 represents a reasonable fit, and that an 8 year mean does not. It appears that the fitted curve represents only a lower limit, and that the true mean is somewhere between 16 and 20 years. However the most recent data update (July 1988) suggests that the data will converge at a mean incubation time approximating 18 years, with a Weibull shape factor of B=2.3. We recognize that this suggests a much longer incubation time than previous estimates but may be explainable, in part, from the work of Wolinsky et al reported at the last conference in Stockholm which suggested a dormant period between infection and expression of antibodies of as much as four years. From our curves we estimate that a minimum of 20,000 and perhaps a maximum of 50,000 transfusion-related cases of HIV remain undetected.

Th.A.P.61 INCUBATION TIME FOR AIDS IN TRANSFUSION-ASSOCIATED CASES : AN ESTIMATION FROM THE FRENCH DATASET

Costagliola, Dominique*, Laporte, A***, Valleron, A-J.*
*INSERM U 263, Université Paris VII, Paris, France, ***Direction Générale de la Santé, Paris, France.

Objective : To calculate estimates for mean and median incubation times for AIDS, and to give confidence intervals for these two parameters using the French dataset.
Methods : The method described by Lui *et al.* was selected and as in several previous works, a Weibull or a gamma distribution for incubation time were postulated. The Likelihood Ratio Statistic (LRS) was used to derive 90% confidence intervals. The French dataset where each case was individually reviewed, was used. Ninety two (92) cases with multiple transfusion, single transfusion without knowledge of the time of transfusion, association of another possible major risk factor of transmission were eliminated, leading to a final dataset of 167 subjects. Due to the age dependance of incubation time, the analysis was restricted to the 148 subjects 13 years of age or older.

Results :	Weibull	Gamma
Mean (Years)	5.3	6.9
90% CI	4.4 - 8.9	4.9 - 19.0
Median (Years)	5.3	6.4
90% CI	4.4 - 8.8	4.6 - 17.1
Log likelihood	-509.2	-508.6

Conclusion : Similar fits were observed with both distributions. Confidence intervals, under the Weibull assumption in particular, are narrower than those previously published. This indicates that an accurate estimate for mean incubation time in transfusion-associated cases will probably be obtainable in the near future.

Th.A.P.63 MODELLING PROGRESSION OF HIV INFECTION

De Gruttola, Victor*, Lange, Nicholas**
*Harvard Univ., Boston, MA, **Brown Univ., Providence, RI U.S.A.

Statistical modeling of progression of HIV infection is made complicated by two problems: 1) follow-up of infected patients is generally much shorter than the average time from infection to AIDS, and 2) the times of infection are generally unknown. As a consequence, it is difficult to distringuish between different models for progression of markers of HIV infection, such as T-helper cell count. Some investigators have proposed that decline is gradual until shortly before onset of AIDS, but available data do not permit rejection of models with fairly constant decline over the entire latency period. The ability to discriminate among models can be enhanced by incorporating information about the distribution of infection-time among HIV seropositive people and of markers among the seronegative. This can be achieved through use of growth curve methods that treat the time of infection as a random effect whose distribution is estimable, either from the data on progression itself, or from external cohorts. This methodology was applied to data on progression of T-helper cell count in 426 HIV-infected men from the Men's Health Study in San Francisco, using a estimate of the infection-time distribution for the whole city. Based on our preliminary analysis, it is difficult to reject the hypothesis of a slow, steady decline in this marker. Assuming a constant rate of decline, roughly two-thirds of infected men would be expected to have annual drops in T-helper count between 88 and 140. When the model was expanded to include a quadratic term, there was slight evidence of a slowing of the rate of decline; but after 5 years, the slope was reduced by less than 10%.

Th.A.P.65 SIMULATING THE EPIDEMIC DYNAMICS OF HIV-INFECTION USING STOCHASTIC PROCESSES OVER RANDOM GRAPHS

Georg F. Bols, Ph. Blanchard, T. Krüger
Fakultät für Physik, Universität Bielefeld, D-4800 Bielefeld 1, FRG

Objective: To develop and apply to the epidemic dynamics of HIV-infection a mathematical model and simulation procedure which incorporates the structure of sexual contacts inside a society and reflects the inherent stochasticity of the transmission dynamics. To gain insight into the microdynamics of the transmission process and use it to draw conclusions for possible prevention strategies.
Methods: The model consists in a random graph, encoding the sexual contact structure of a society, specified by social parameters, on which a discrete time stochastic process evolves, representing the spread of infection, specified by medical and social parameters. Thus, in computer simulations, a very detailed description of the configuration as well as of the dynamics is possible, including e.g. parameters defined via distribution functions, social preferences in partner selection, regional structure, time dependent infectivity. The set of observables allows for a close look at the fine structure of the transmission process. Hence, not only will the overall estimates on the course of the epidemics be improved, but typical infection paths can be followed and investigated, and effects of prevention strategies can be modelled at the scale of the individual.
Results: In comparison with differential equation models, the most remarkable features of the model are: transport from the highly promiscuous part of the homosexual population into the heterosexual population with low partner numbers is slowed down by the finite width of the interfaces, i.e. the groups acting as mediators; inside the majority of the heterosexual population, the epidemics growths with finite speed rather than exponentially due to low partner number and low rate of partner change. A scenario, where direct counselling to infected individuals and their present and past partners affects specifically their behaviour, is simulated and its efficacy discussed.
Conclusion: Incorporating the sexual contact structure into an AIDS-model is essential. The spread of infection is strongly determined by the graph structure. The model indicates that, if the actual growth inside the heterosexual population is slower than expected from the early growth pattern amongst homosexuals, this might be due to slow transport into this group while it may not necessarily be taken as a sign of significantly lower transmission rate or of low penetration depth of HIV-infection into the heterosexual population.

Th.A.P.62 HETEROGENEITY IN THE INCUBATION TIME OF AIDS: A STOCHASTIC SERIAL COMPARTMENT MODEL.

FIROZE MANJI*, NAGELKERKE N*.,PLUMMER F.A**
Kenya Medical Research Institute*, University of Nairobi,Nairobi, Kenya**.

OBJECTIVE: To determine if stochastic processes could account for the observed heterogeneity in the development of AIDS.
METHODS: We hypothesize that prior to developing AIDS (S_v) individuals must pass through a series of intermediate stages ($S_1,S_2,S_3....S_{v-1}$).The transition to AIDS is irreversible.If the transition probability between S_k and S_{k+1} is stochastic with an exponential distribution the probability of developing AIDS after time t is $F(t)=b_1e^{-\mu_1 t} + b_2e^{-\mu_2 t} +....+ b_v e^{-\mu_v t} + F(\infty)$ where F(t) is the fraction of HIV infected individuals ultimately developing AIDS at time t.
RESULTS: Taking $\mu=3$ and $S(\infty)=1$ gives a family of curves which mimic the Gamma and Weibull distributions in the early part of the curve and fit the empirical data well but are much more variable in the tail.
CONCLUSION: Stochastic processes can account for the observed heterogeneity in the incubation of AIDS.

Th.A.P.64 "STRUCTURED" AND "SELECTIVE MIXING FORMULATIONS OF HETEROGENOUS CONTACT TO STUDY HIV TRANSMISSION

Koopman, James; Jacquez, John; Simon, Carl. University of Michigan, Dept. of Epidemiology SPH-1, 109 Observatory, Ann Arbor, MI, U.S.A.

Objective: Provide a mathematical and theoretical context as well as questionnaire suggestions for the study of sexual and needle contact patterns affecting the course of the AIDS epidemic.
Methods: We have developed a mathematical theory and model of contact structure which proceeds from the assumption that there are two forces creating heterogenous sexual and needle contact patterns in a population. The first is the choice of social contexts for meeting potential sexual partners. We model this with a formulation called "Structured mixing". The second is the degree of selectivity exercised in choosing partners among those who are encountered in these social contexts. We model this with a formulation called "Selective mixing".
Results: The two formulations combine into one overall theory in different ways depending upon how information is collected on the social contexts of sexual or needle sharing partnerships. Information may be collected on the social contexts where actual partnerships were made, on where sexual attraction was felt or the opportunity to share needles presented itself, or on more general social contacts. For each of these approaches, there are different approaches required to collect information on the selection of partners. We demonstrate how predictions of the future course of the epidemic and estimates of the relative risk of oral and anal sex are very sensitive to contact structure information. We also illustrate how to collect such information.
Conclusion: Epidemiologists have tended to disregard questions about who has sex or shares needles with whom in their investigations because they lack an overall theory to guide the collection and analysis of such information. This deficiency could be causing us to misjudge the risks associated with different behaviors (especially to underestimate the risk associated with oral sex). It is also retarding the analyses of where we might expect the epidemic to spread next. Our structured and selective mixing model provides a basis to overcome this deficiency.

Th.A.P.66 A RISK BASED HETEROSEXUAL MODEL OF THE SPREAD OF HIV

Stanley, E.A., Hyman, James M., Colgate, S.A. and Layne, S.P.
Los Alamos National Laboratory, Los Alamos, New Mexico 87545 USA.

Objective. To understand how social behavior influences the spread of HIV and the difference between spread in heterosexual and homosexual populations.
Method. We extend a model for the homosexual spread of HIV to include heterosexual spread. The population is distributed by partner change rate, which is assumed to be the primary social variable determining mixing patterns. Variation in infectivity and progression to AIDS are accounted for. Mixing between groups with different risk behaviors is determined by an acceptance function, which can bias partnerships to form between individuals with similar risk behaviors, or can allow mixing to be determined by availability. We can use our model to study the effect of a different female to male than male to female transmissibility. We also can examine the spread of the infection from the homosexual to the heterosexual community via bisexual contacts.
Results. Models can help us understand better how the AIDS epidemic is spreading and which intervention strategies might be most effective. The mixing function largely determines the growth of the model epidemic. If individuals select partners with similar behavior, the epidemic progresses as a wave from high risk to low, with an increasing doubling time determined by the risk groups at the front of the wave. If individuals are less discriminate in partner choice, the epidemic has a more constant doubling time, determined by the "most likely" partner group. Initially growth is slower, but it quickly surpasses the biased mixing case. If transmissibility is significantly different from women to men than from men to women, then strategies for stopping the epidemic may be different than if they are the same.

Th.A.P.67 CHALLENGES IN MODELING HIV INFECTION IN LOW SEROPREVALENCE POPULATIONS

Watters, John K.
University of California, San Francisco, California, U.S.A., Urban Health Study, San Francisco, California, U.S.A.

Objective. To explore the difficulties in developing predictive models of HIV infection in populations with low prevalence of markers of infection.
Methods. Data from a cross-sectional study of intravenous drug users (IVDUs) collected in six waves since 1986 are examined (N=3,700). Results of various regression equations that examine the predictive power of known risk factors are contrasted. These models are also compared to models developed in high prevalence populations.
Results. In San Francisco, HIV-1 seroprevalence in heterosexual IVDUs has remained relatively stable at less than 15% between 1987 and 1989. However, distribution of virus is heterogeneous with significant variations both between ethnic groups and neighborhoods of residence. Black, heterosexual IVDUs (n=871), for example, were more likely to be HIV-1 seropositive than their white counterparts (n=748) over the period 1987-1 to 1989-1 (O.R. 1.6, 95% C.I.=1.2, 2.1). In one San Francisco neighborhood (the Tenderloin District) risk of HIV-1 infection among heterosexual IVDUs (n=165) was twice that of IVDUs residing elsewhere in the city (n=476) in 1989-1 (O.R.=2.2; 95% C.I.= 1.3, 3.7). Nevertheless, risk factors predictive of HIV infection in other studies of IVDUs (eg. frequency of injection, use of shooting galleries, and numbers of sharing partners), failed to consistently predict HIV infection.
Conclusion. Predictive models that identify independent risk factors contributing to HIV infection among high seroprevalence populations where distribution of virus is relatively homogeneous may not apply to the large number of cities with relatively low HIV infection rates among heterosexual IVDUs. This is likely due to heterogeneity in distribution of infection markers in low prevalence populations. This tends to erode the predictive power of independent variables that appear to reliably predict infection in populations with more homogeneous distribution of markers. Model construction in low prevalence, heterogeneous populations must examine the separate risk ecologies that may differ widely among cultural groups and from neighborhood to neighborhood.

Th.A.P.68 ESTIMATING INTRAVENOUS DRUG USER (IVDU) POPULATION FROM AIDS STATISTICS IN SAN FRANCISCO.

Biernacki, Patrick; Aldrich, M.; Mandel, J..
Youth Environment Study, Inc., San Francisco, CA USA.

Objective. To present a method by which to estimate the size and demographic makeup of populations at high risk for AIDS, with San Francisco IVDUs as an example.
Methods. Back-calculating the number of HIV-infected IVDUs from infection to AIDS; applying seropositivity levels to determine IVDU population size.
Results. A single-page computer spreadsheet illustrates how the number of IVDUs at risk for AIDS can be back-calculated from reported variables. In San Francisco this further split by ethnicity, age, sex and neighborhood.
Conclusions. Population size can be estimated using reported AIDS and HIV seropositivity measures. AIDS surveillance accuracy and HIV-related non-AIDS diseases must be considered in making such estimates.

Th.A.P.69 AIDS IN THE NORDIC COUNTRIES - FORECASTS

Eriksson, B.
Nordic School of Public Health
Gottenburg, Sweden.

The numbers of new AIDS-cases per year in the Nordic countries are given below.

Year	Before 1983	1983	1984	1985	1986	1987	1988
Cases	7	20	34	83	145	204	267

A demographic model where birth corresponds to becoming HIV-infected and death to developing AIDS was used to summarize the series and to produce forecasts. Through trials and using a least squares criterion, a model with 270 HIV-infected in 1982 and a yearly incidence of 0.05 among the infected was adopted. The rate of virus transmission used to fit the model was 1, i.e. every infected person infects one other person during each year. Data fit well to this model up to an including 1986. The model gives 271 cases in 1987 and 522 in 1988. Thus, a certain reduction of transmission seems to have occurred from about 1986. A 60% yearly reduction was estimated. Under these assumptions, the epidemic is now close to its peak (275 cases). The number of new cases per year will start slowly to decrease to about 170 by the year 2000. A substantial number of new cases per year will appear, however, for a long time in spite HIV-transmission will be very small from about 1995, which is an optimistic prospect.

Similar calculations have been made for the two Nordic countries with the highest numbers of cases, Denmark and Sweden, the results pointing in the same direction.

Th.A.P.70 EFFECTS OF MODELING HETEROGENEITY OF DRUG USE BEHAVIOR

Siegel J*, Weinstein M*, Shepard D*, Watters J**, Fineberg H*.
*Harvard Schl of Public Health, Boston MA
**University of California at San Francisco, San Francisco CA

Objective. Intravenous Drug User (IVDU) risk behaviors vary widely. Heterogeneity of behavior may affect predictions of the spread of HIV obtained in epidemic models. This research examines effects of heterogeneity in a model to assess the effectiveness of intervention programs targeted to IVDUs.
Methods. Data are from a survey of 603 IVDUs in San Francisco (Urban Health Study 1988). Measures of injection frequency, needle sharing, and needle-sharing partners were obtained. We use a model of HIV transmission incorporating estimates of these risk behaviors, as well as data on HIV incubation and motality from published sources, to predict life expectancy (LE), intervention effectiveness, and medical care costs. Heterogeneity is modeled in ways consistent with the original San Francisco data.
Results. Results obtained from all models considering heterogeneity of risk behaviors show higher life expectancy than baseline results obtained using the overall parameter means.

Model	LE (Years)	Δ LE
Homogeneous Risk Groups	13.0	1.4
Heterogeneity of Injection Freq (Modeled in 3 Groups)	14.4	1.7
Heterogeneity of Injection Freq (Modeled in 27 Grps)	14.6	1.5
Modeling of Extremes of Inj Freq (Upper, Lower 10%)	14.0	1.5
Heterogeneity of 3 Parameters Simultaneously (Indep)	16.4	1.4

Conclusion. Simulations suggest that in modeling the spread of HIV among IVDUs, an assumption of homogeneity of risk behaviors is likely to result in an overestimate of epidemic spread. It will be important to attend to both qualitative and quantitative evidence of heterogeneity in addressing AIDS among IVDUs.

Th.A.P.71 A HETEROSEXUAL MODEL FOR THE SPREAD OF HIV AND THE DEMOGRAPHIC IMPACT OF THE AIDS EPIDEMIC

Stanley, E. Ann*, Seitz, S.T.***, Way, P.O.**, Johnson, P.D.**, Hyman, J.M.*, Curry, T.F.****, et al.
*Los Alamos National Laboratory, Los Alamos, NM 87545 USA, **U.S. Bureau of the Census, Washington, DC, USA; *** University of Illinois, Champaign, IL, USA, ****U.S. Air Force Academy, Colorado Springs, CO, USA.

Objective. To model the spread and demographic impact of HIV and AIDS.
Method. We have developed an age-structured model of the spread of HIV to study the impact of the epidemic on nations where the primary model of transmission is heterosexual. This model builds on the work of J. Bongaarts. It divides the population into promiscuous--characterized by one-time sexual contacts--and nonpromiscuous groups. We model the flow of infection between urban and rural areas through migration. Modules for transmission of HIV perinatally and by blood transfusion, for marriage formation and dissolution, fertility, and non-AIDS mortality are included.
Results. The results are available through a window-based interface. The age-specific results include: uninfected and infected populations, by time since infection; the number of new HIV infections and AIDS cases; deaths from AIDS and from all other causes; the impact of AIDS on the population age structure; and the spread of HIV from urban areas to rural areas.
Conclusions. A comprehensive model of the heterosexual spread of HIV infection and AIDS has been developed to analyze the possible future course of the epidemic. Continuing changes and enhancements to this model in the future will include the provision for the homosexual spread of the virus.

Th.A.P.72

ESTIMATION OF THE EFFECT OF AZT ON TIME TO AIDS IN HIV-INFECTED SUBJECTS FROM OBSERVATIONAL DATA

Robins, James. Harvard School of Public Health, Boston, Ma. USA.

The NIH has recently put out an RSP for community-based non-randomized studies of the effect of treatments such as AZT on time to AIDS among HIV-infected subjects. In such observational studies, T4 count history may be simultaneously a confounder and an intermediate variable. T4 history is a confounder since subjects with low T4 counts are both at an increased risk of developing AIDS and more likely to receive treatment with AZT. T4 count history will be an intermediate variable if AZT delays time to AIDS by inhibiting viral destruction of T4 cells. When a time-dependent risk factor like T4-count is both a confounder and intermediate variable, all standard statistical methods (such as Cox's proportional hazard model) may result in a biased estimate of the AZT effect on time to AIDS whether or not one adjusts for the covariate T4 count history in the analysis.

In this paper new statistical methods will be described that allow for proper control of confounding by intermediate variables such as T4 count history. These methods estimate the parameters of a new class of models, the nested structural failure-time models, using a class of instrumental variable estimators, the G-estimators. Relationships between G-estimators and (a) non-linear 3-stage-least-squares estimators and (b) Robins' (1986) G-computation algorithm and G-null test are discussed. User-friendly software available for analysis is described.

Th.A.P.73 SIMULATION OF HIV TRANSMISSION IN A STRUCTURED COMMMUNITY OF INTRAVENOUS DRUG USERS

Denton Peterson, Keith Willard and Michael Altmann University of Minnesota and VA Medical Center, Minneapolis, Minnesota USA.

An Intravenous (IV) Drug Community/HIV Transmission model has been developed to help evaluate public health intervention programs. The model uses Monte Carlo simulation to determine when an IV drug user contacts HIV and how the HIV infection progresses. The HIV progression model reproduces the stages of HIV infection: virus contact, asymptomatic stage, beginning symptoms, ARC, AIDS, and death. The population model of an intravenous drug community simulates its dynamics: 3 types of addicts, differentiated by amount of drug use; a process of recruitment to addiction and to heavy addiction; withdrawal during incarceration and treatment programs; recovery from addiction; and death from non-HIV-associated causes. The IV drug community is structured into a social network based on literature reports. Users are exposed to HIV through sharing needles with acquaintances in their social network, strangers in the general population and in "shooting galleries." The probability of HIV transmission given contact with contaminated needles is estimated from reports of zero-positive rates in health care workers exposed to HIV needle sticks. The model is flexibly structured and has been adapted to populations representing different geographic areas having unique social structures, exposure characteristics, and underlying HIV prevalence . Simulations of a needle exchange program and increased treatment indicate the importance of prevalence in determining the long-term success of intervention.

(Supported in part by NIH RR-1632 and the Veterans Administration)

Th.A.P.74 REVERSE EXTRAPOLATION AS A METHOD FOR ESTIMATING HIV SEROPREVALENCE

Soskolne, Colin L; McGregor, J.R. and Jaroni, A.N.
University of Alberta, Edmonton, Alberta, Canada.

Objective. To provide a method for estimating HIV prevalence.
Methods. Reverse extrapolation is applied to 8 and 10 year AIDS projection estimates. Current infection prevalence then is calculated based first on one assumption which states that approximately three times as many people presently are infected as will actually develop AIDS 8 years hence; a second assumption used is that twice the number of those who will develop AIDS 10 years hence already are infected.
Results. Seroprevalence can be estimated for regionally defined groups for whom AIDS projections can be determined. For example, from AIDS projections for the province of Alberta through July 1988, determined by the Poisson, polynomial, logistic, and doubling time models, a lower estimate of 3,464 and an upper estimate of 4,978 were obtained. The then current provincial AIDS total was 117 case reports. Equivalent estimates for Canada, at a time when the cumulative total number of AIDS cases was 1,941, were in the range 30,742-186,882, with a most likely value around 100,000.
Conclusion. The method appears reliable since it produces findings consistent with those of others. It is both robust and cost-effective. However, it is no substitute for valid data gleaned directly through seroprevalence surveys of defined groups. Actual reliability will be established when results from seroprevalence surveys are available for comparison.

Th.A.P.75 THE PREDICTION OF THE NUMBERS OF AIDS CASES IN THE UK, AND THE ESTIMATION OF THE INCUBATION PERIOD OF AIDS.

Medley, Graham and Anderson, R.M.
Department of Biology, Imperial College, London SW72BB, UK .

Objectives: To use available data to forecast the future numbers of diagnosed AIDS cases in the UK.
Methods: Mathematical models are described that use a) the numbers of reported cases in the UK to predict future cases, and b) data available for estimating the incubation period of AIDS.
Results: Previous estimates of future UK AIDS cases (*Short-term Prediction of HIV Infection and AIDS in England and Wales*. HMSO, London, December 1988) and the incubation period of AIDS (Medley *et al*, Nature 1987, 328, 719-721; Anderson & Medley, Epidemiology of HIV Infection and AIDS: Incubation and Infectious Periods, Survival and Vertical Transmission. AIDS 1988, in press) are updated.
Conclusions: The results are discussed in terms of their implications for the AIDS epidemic in the UK and other industrialised countries.

Th.A.P.76 PROJECTING LOCAL AIDS INCIDENCE USING BOTH SURVEILLANCE AND SEROPREVALENCE MEASURES

Byers, T., Ferris, Laura, LeTourneau, J., Hull, H. and Wilson, J.
New Mexico Health and Environment Department. Santa Fe, New Mexico, U.S.A.

Objective. To project AIDS incidence through 1992 for the State of New Mexico by two different methods: one which extrapolated from past AIDS surveillance data, and one which projected future cases based on current HIV seroprevalence estimates.
Methods. The surveillance-based projections were derived directly from recent US national projections. The future proportions of all US cases expected to occur in New Mexico over the next four years were projected as a linear extrapolation from those proportions observed in the last four years in local AIDS surveillance data. The HIV seroprevalence-based projection method used various recent local seroprevalence surveys to estimate the number of New Mexicans currently infected with HIV. Future AIDS incidence was then projected for those currently infected, as well as for those expected to be infected by future transmission, by specifying assumptions for each risk group about their duration of HIV infection and expected future AIDS incidence.
Results. Both projection methods produced similar estimates through 1992. 944 cumulative cases were predicted by the surveillance method and 1033 were predicted by the seroprevalence method. Back-calculation of the number of "expected" cases for 1988 based on the assumptions used in the seroprevalence-based method produced a number of cases which was very similar to that actually observed, thus the seroprevalence-based estimates seem reasonable.
Conclusions. This analysis demonstrates that both surveillance and seroprevalence measures can be useful in developing local AIDS projections.

Th.A.P.77 RELIABILITY OF ESTIMATES BASED ON BACKCALCULATION.

Mitchell H Gail, PS Rosenberg, RJ Biggar, JJ Goedert. NCI, Bethesda, MD , R. Brookmeyer Johns Hopkins, Maryland, USA

OBJECTIVE: To assess random and systematic uncertainties in estimates from backcalculation of the cumulative numbers of HIV-infected persons up to 1985 and through the present, the differences between average infection rates over previous time intervals, and projections of future AIDS incidence. METHODS: Using flexible models of the previous HIV infection rate, we evaluated the effects on the estimates above to uncertainties in the AIDS incubation distribution, the form of the infection rate curve, delay corrections, and changes in the surveillance definition. Our method yielded variances for random errors as well as an assessment of the systematic errors, such as from misspecification of the incubation distribution. RESULTS: We studied persons with hemophilia and non-IV drug using homosexual men using a Weibull AIDS incubation distribution F(t)=exp(-0.002t^2.516) derived from persons with hemophilia. We find evidence for an earlier peak in infection rates in these two test cases, in line with independent epidemiologic evidence. These results suggest that valid inferences may be made for other risk groups. Sensitivity analyses indicated that near term projections of AIDS incidence were relatively stable with respect to perturbations of the underlying model. However, estimates of the cumulative number of infections occurring after 1985 and estimates of changes in the infection rate have large random and systematic components of error. CONCLUSIONS: Our results help us to assess the strength of substantive inferences made using the method of backcalculation.

Th.A.P.78 A REVIEW OF SOME TECHNIQUES FOR BACKWARD ESTIMATING THE PREVALENCE OF HIV FROM AIDS CASE INCIDENCE

Philip C. Cooley[*]; Reade-Christopher, S.[*]; Hamill, D.[*] and van der Horst, C.[**]
[*]Research Triangle Institute, Research Triangle Park;
[**]University of North Carolina at Chapel Hill, Chapel Hill, N.C., USA.

Objective. Some methods for estimating HIV prevalence from AIDS case data are examined. Featured in this examination is the Brookmeyer-Gail method.
Methods. Validity of the methods are examined by performing sensitivity analysis of the HIV prevalence estimate by year for different incubation distributions.
Results. An estimate of U.S. HIV prevalence is produced.
Conclusion. The Brookmeyer-Gail method is an objective procedure for estimating past HIV prevalence but a proper representation of the incubation distribution is critical in providing reliable estimates.

Th.A.P.79

PROJECTING PROPORTIONS OF AIDS CASES OVER TIME

Karon, John M.; Devine, OJ
AIDS Program, Centers for Disease Control, Atlanta, GA, USA

Objective. To model time trends in the proportions of AIDS cases in groups, in order to make short-term projections of future proportions.
Methods. Let $p_i(t)$ be the proportion of cases in group i, i=1,2,...,G, at time t. Model the generalized logits: $\log(p_i(t)/p_G(t)) = f_i(t)$ + error, where $f_i(t)$ is a polynomial in time (estimated using weighted regression) and group G is the reference group ($f_G(t) = 0$). Predicted proportions are:

$$p_i(t) = \exp(f_i(t)) / \Sigma \exp(f_i(t)).$$

Results. Predictions are nearly independent of the choice of the reference group. We modeled quarterly incidence of U.S. cases for Jan 1984 through June 1988 grouped geographically into metropolitan statistical areas: New York City, San Francisco, Houston, and others (reference group). Linear polynomials give good fits to observed proportions and predict decreases in each area, with the following observed and predicted percent of U.S. cases:

	New York City		San Francisco		Houston	
Quarter	Obs.	Pred.	Obs.	Pred.	Obs.	Pred.
1987/1	18.6	18.3	6.4	6.6	3.1	3.3
1988/1	17.4	17.5	5.9	5.4	2.9	2.8
1989/4		12.1		3.9		2.6

Conclusion. Modeling proportions can give useful short-term projections even with relatively few cases in some groups. Proportions in risk groups can be modeled after the effects of the new case definition on trends are understood. Estimates of uncertainty and prediction intervals can be obtained from a multinomial likelihood incorporating similar models.

Th.A.P.80

THE AIDS EPIDEMIC IN MEXICO

Alejandro Mohar,* V. De Gruttola,* J.L. Valdespino,** L. Garcia,** and J. Sepulveda.**
*Harvard University, School of Public Health, Boston, MA.
**General Directorate of Epidemiology, Ministry of Health, Mexico City, Mexico.

Objective: To predict the short term course of the acquired immunodeficiency syndrome (AIDS) epidemic in Mexico.
Methods: By the method of back calculation using cumulative number of AIDS cases reported until October 1988 and adjusting for report delay for right-truncated data in chronologic time, we estimate the future number of AIDS cases in Mexico. The analysis comprises the results of the National Serum Survey (NSS) which is intended to provide a reliable estimate of the current HIV seroprevalence in the entire country of Mexico.
Results: Initial analysis adjusted for the report delay demonstrates that there are significant differences in AIDS reports by risk factor (homosexuality vs. others) and by region (Mexico city vs. others). The results of the "working backwards" modelling, with consolidated results of the NSS, will be presented.
Conclusion: The authors considered that the method of back calculation with adjustment for report delay in conjunction with a reliable estimate of seroprevalence will substantially improve the accuracy of their projections. This analysis will give better insight into the future course of the AIDS epidemic.

Th.A.P.81

MODELLING OF THE AIDS EPIDEMIC IN MEXICO

Isabelle Romieu,* S. Sandberg,* T. Awerbuch,* A. Mohar,* J.L. Valdespino,** J. Sepulveda,** et al.

*Harvard University, Boston, MA, USA; **Direccion General de Epidemiologia, Mexico DF, Mexico.

Objective: To forecast new AIDS cases among different risk groups in Mexico, and determine the impact of preventive measures on the spread of the epidemic.
Methods: We used a closed compartmental model to forecast new AIDS cases among homosexual and bisexual males, and heterosexual males and females. For each group three compartments were defined: uninfected persons, infected but asymptomatic persons, and diagnosed AIDS cases. It is assumed that the AIDS epidemic will follow the propagation of infectious disease model, where spread of infection is proportional to the product of the number of healthy persons and the number of infected persons. The only movement inside the system is from healthy to infected, and from infected to asymptomatic, and symptomatic people do not spread the disease. A discrete non-linear regression was used to estimate the parameters of the model so that the prediction would fit the number of reported AIDS cases in Mexico. The impact of preventive measures was determined by modification of the probability of transmission of HIV.
Results: By August 1988, 1811 cases had been diagnosed in Mexico, 768 were homosexual males, 375 bisexual males, and 118 heterosexual males and females. Our model predicts that the AIDS incidence will continue to rise in Mexico for at least the next 8 years and will spread among the heterosexual population. By means of education programs, decreasing the transmission probability by 10% in all groups will result in a decrease of 24% in the number of cases accumulated over an 8 year period. A 20% decrease would prevent more than 40% of the cases.
Conclusion: Simple models can be valuable to predict the evolution of the AIDS epidemic and the impact of behavioral change.

Th.A.P.82

LIMITATIONS OF OFFICIAL FORECASTS USED IN PLANNING FUTURE AIDS SERVICE NEEDS

Green, James; Leigh, M.; Wintfeld, N.
New York University Medical Center, New York, New York, USA.

Objective. To compare official and semi-official projections of AIDS prevalence and associated medical/social service needs among city, state, and federal agencies for New York, San Francisco, Los Angeles, and other U.S. cities. To explain how assumptions and choice of methodology affect these projections.
Methods. Critical review of published forecasts.
Results and Conclusions. Responsibility for projecting prevalence and service need has shifted from the federal to state and local levels in the past few years. The earliest projections of AIDS prevalence were made by the Centers for Disease Control (CDC) in 1986 for San Francisco, New York City, and the U.S. as a whole. The Institute of Medicine's estimates of hospital need through 1991 were based on these CDC projections. Major official strategic plans have recently been completed by interagency task forces in San Francisco, New York City, and New York State which include case projections broken down by risk group and forecasts of need for hospital beds, long term care beds, housing, and other service needs.

Unofficial forecasts using competing methods often differ sharply from official projections. The key differences among the forecasts result from the choice of assumptions (e.g., history of HIV infection among specific risk groups, future infection rates, disease progression rates, and reporting lags) and projection method (linear or polynomial extrapolation from incidence time series data vs. simple or complex biological models based on estimation of infection and disease progression). We describe how choice of assumptions and methods affect official forecasts for various cities and examine alternatives.

Histoire clinique de l'infection à VIH
Natural History of HIV Infection

Th.A.P.83

GENETIC EPIDEMIOLOGY OF AIDS. L Louie, S Desmond, K Gilles, B Newman, and M-C King. University of California, Berkeley, CA 94720, USA. We are currently addressing two crucial questions about the epidemiology of AIDS: 1) Does host genotype influence susceptibility to HIV infection? 2) Does host genotype influence the rate of disease progression once a person is infected with HIV? Our first study sample, from the San Francisco Men's Health Study (SFMHS), consists of 88 Caucasian men in 4 clinical groups: 1) HIV- despite high risk behaviors; 2) HIV+ with no symptoms for at least 2 years; 3) HIV+ with at least 2 clinical findings but without AIDS; and 4) AIDS. Our second study sample consists of 46 Caucasian AIDS patients from the AIDS Clinical Research Center (ACRC) in San Francisco and 76 healthy Caucasian controls. In both samples, we are comparing sequences of genes involved in immune response by analysis of DNA polymorphisms.

Our first results are for T cell receptor-beta chain (TCRB), which is detected by the cDNA probe PT10 after digestion of genomic DNA with Bgl II. Alleles have fragment lengths 10.0 and 9.2 kb. In the SFMHS sample, allele frequencies did not differ between the HIV- group vs the three HIV+ groups (χ_1^2=1.65, p=.20). Among HIV+ men, asymptomatic subjects did not differ from symptomatic and AIDS patients (χ_1^2=.04, p=.84). In the ACRC sample, allele frequencies did not differ between AIDS patients and healthy controls (χ_1^2=.02, p=.89). We are continuing to screen other candidate sequences involved in immune response and will present these results at the meeting.

Group	Clinical Status	TCRB Allele		N
		10.0 (%)	9.2 (%)	
SFMHS 1	HIV-	28 (48)	30 (52)	29
2	HIV+, asymptomatic	18 (36)	32 (64)	25
3	HIV+, symptomatic	21 (40)	31 (60)	26
4	AIDS	4 (29)	10 (71)	7
ACRC	AIDS	51 (55)	41 (45)	46
Controls	Healthy	89 (56)	69 (44)	79

Th.A.P.84

EVALUATION OF THE IMMUNOLOGICAL STAGING SYSTEM IN A POPULATION BASED COHORT

Royce, Rachel*; Winkelstein W Jr*; Anderson R**; Lang W**.
*University of California at Berkeley, **ViRx Inc., San Francisco, CA, USA.

Objective. To apply the immunological staging system, ISS, (Zolla-Pazner, 1987) to a sample of HIV infected men. To determine risk of AIDS by ISS stage after 42 months of observation, and pattern of change in stage.
Methods. ISS Stages 1-3 are composed of an additive combination of immunological abnormalities: CD4/CD8 T cell ratio of <1.0, CD4 T cell count of <500 cells/ul, and lymphopenia of <1500 cells/ul. Lack of abnormalities defines Stage 0. The 368 HIV infected men, initially AIDS-free, of the San Francisco Men's Health Study probability sample were staged at visit 1 by the ISS and re-classified every 6 months at follow-up visits 2-8. Risk of AIDS by initial stage was determined after 42 months follow-up.
Results. At visit 1, 2 men were unclassifiable by the ISS. The remaining 366 men were distributed among Stages 0-3 as follows: 16%, 58%, 21%, and 5%. The risks of AIDS and 95% confidence limits after 42 months were .02 (.003,.09), .14 (.10,.19), .43 (.32,.54) and .18 (.06,.41) for Stages 0-3.

All but 11 men were classifiable on visits 2-8. By visit 8, 62% had changed to a higher stage relative to visit 1. Of classifiable men with at least 1 follow-up visit, 141 (42%) regressed in stage at 1 or more visits.

The relatively low risk of AIDS in Stage 3 on visit 1 may be artifactual because men in Stage 3 on visit 2 and visit 3 had higher risks of AIDS at 30 months follow-up, .55 (.35,.73) and .35 (.21,.53) respectively.
Conclusion. ISS is easily applied and predicts progression to AIDS. Men do not appear to move uniformly through the stages. Stage 3 which is based on lymphopenia, may not describe a risk of AIDS distinct from the other stages.

Th.A.P.85

TIME FROM FIRST HIV INFECTION TO PERSISTENT ANTIGENEMIA

Chmiel, Joan*; Munoz A**; Phair J*; MacDonell K*; Carey V**; and Tsung L*. *Northwestern University Medical School, Chicago, IL; **The Johns Hopkins University School of Public Health, Baltimore, MD, USA.

Objective. HIV antigenemia is an important predictor, independent of CD4 cell number, for progression to AIDS in the Chicago MACS prevalent seropositive cohort. The objective of this study was to assess the usefulness of HIV antigenemia as an indicator of time since first HIV infection.
Methods. For each of 439 HIV antibody positive (Ab+) men in the Chicago MACS with baseline antigen (Ag) capture results, an estimate of time since first infection was established using %CD4 and platelet count (Munoz et al. IV International AIDS Conference). Means and ranges of the mean times since first infection for men with and without antigenemia at entry were compared. Development of antigenemia in 47 HIV antibody seroconverters(SC) was examined to assess the validity of our estimates.
Results. 366 Chicago MACS participants who were HIV Ab+, Ag- at entry had an estimated mean time from first HIV infection to study entry of 19.0 mos. (range 17.1-21.1), compared to 28.1 mos. (range 19.8-72.2) for the 73 Ab+ men with Ag detected at entry (p<0.001). Approximately 75% of this latter group had Ag that persisted for at least 2 consecutive 6 mo. visits. The observed times from SC to detection of persistent Ag ranged from 3 to 30 mos.(7 men); 8 SC developed Ag that did not persist.
Conclusion. Persistent antigenemia in a seropositive cohort is informative about the time since initial HIV infection. Estimation of this time may be useful for describing progression of HIV disease when CD4, platelet count, and antigen status are known.

Th.A.P.86

LONG-TERM HIV INFECTION WITHOUT CLINICAL ILLNESS OR IMMUNODEFICIENCY: HOMOSEXUAL MEN WHO HAVE NOT "PROGRESSED"

Lifson, Alan R.*; Buchbinder,S*; Sheppard,H**; Wilber J*; Hessol,N*; Mawle,A****; Hart,C****; Stanley,M***; O'Malley,P*; Rutherford, G*. *Dept Public Health, San Francisco, CA; **CA Public Health Foundation, and ***Pathology Inst., Berkeley, CA; ****CDC, Atlanta, GA, USA.

Objectives: To evaluate the immunologic and virologic profile of persons with long-term HIV infection who have not developed HIV-disease.
Methods: From a cohort of homosexual/bisexual men, 184 HIV-antibody (Ab) positive men evaluated in 1988 had well defined seroconversion (SC) dates. We compared 37 men who were Ab positive for ≥ 5 y (mean=8.0 y) without clinical evidence of immunodeficiency and who had ≥ 400 T4 lymphocytes (non-progressors [NP]) to 81 men with AIDS or ARC (progressors [P]) (mean=8.2 y); we are conducting additional immunologic tests on NP and P with AIDS (PWA).
Results: T4 count for all 184 men was not statistically associated with year of SC. Compared to P, NP had a higher T4 count, T8 count, and hemoglobin and a lower beta-2 microglobulin. Of those NP tested, 32/32 were negative for HIV antigen, 5/5 were negative for HIV RNA by polymerase chain reaction, and 15/15 were positive either for HIV culture or for HIV DNA by PCR. Compared to 6 PWA, 11 NP did not significantly differ on assays for natural killer activity or Ab-dependent cellular cytotoxicity. When tested by ELISA for Ab to 6 gag, polymerase and envelope recombinant antigens, 11 NP had a higher optical density reading than PWA to p24 and p120N terminal proteins (p<.05).
Conclusions: T4 count is not a marker for duration of infection. NP do not have evidence of replicating virus, but do have evidence of latent HIV infection. Although similar to PWA for some immunologic parameters, NP differed in strength of Ab response to certain core and envelope antigens.

Th.A.P.87

DEFINING THE INTERVAL BETWEEN HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION AND THE APPEARANCE OF HIV ANTIBODY.

Horsburgh, C. Robert*; Ou, C-Y.*; Jason, J.**; Holmberg, S.*; Longini Jr., I.***; Jaffe, H.*; et al.
*AIDS Program and **Division of Host Factors, CDC;
***Emory University, Atlanta, GA, USA.

Objective. Persons infected with HIV who have not developed antibody detectable by currently used tests may transmit the virus through blood donation or sexual contact. This study was done to estimate the duration of this virus-positive, antibody-negative period.
Methods. We investigated 27 homosexual and 12 hemophilic men for whom stored peripheral blood mononuclear cells (PBM) were available before and after seroconversion. PBM were assayed for HIV DNA by the polymerase chain reaction technique using gag and env region primers; serum was tested for p24 antigen by antigen-capture EIA.
Results. Four persons had HIV DNA detected before seroconversion; all had HIV DNA detected only on the seronegative date closest to the time of seroconversion. Three persons had antigen detected before seroconversion; in each case HIV DNA was also detected. Using a Markov model, we estimated the median time from infection with HIV (as assessed by detection of HIV DNA) to first detection of HIV antibody to be 2.4±2.1 (S.E.M.) months. Modeling of reported cases of HIV infection with known exposure gave an estimate of a median of 2.1±0.1 months from exposure to antibody detection, and 95% of cases would be expected in 5.8±0.6 months.
Conclusion. Prolonged periods of unrecognized HIV infection in persons who do not have detectable antibody appear unlikely.

Th.A.P.88

OCCURRENCE OF INDETERMINANT WESTERN BLOT (IWB) TESTS AND LACK OF TRANSMISSION OF IWB IN PERSONS AT LOW RISK FOR HIV INFECTION, HUNTINGTON, WV, USA, 1986-1988

Belshe, Robert*; Schindzielorz, A.* and the NIAID AIDS Vaccine Program**.
*Marshall University School of Medicine, Huntington, WV; **Bethesda, MD, USA.

Background. During screening of prospective volunteers for an AIDS vaccine study (rGP160 MicroGeneSys) we noted the frequent occurrence of IWB in our low risk population. IWB was the most common reason for eliminating volunteers from participating in the study.
Objective. The present study was undertaken to examine the epidemiology of IWB in low risk persons.
Methods. Sera were obtained from three groups: paired sera obtained 1 month apart on 25 families (84 individuals), 34 cord sera paired with sera collected from children 6 to 53 months later and 166 HIV vaccine volunteers. Sera were tested for antibodies by ELISA (Abbott) and WB (Dupont); p-24 antigen (Abbott) was also tested.
Results. No HIV infections were found in our population. Repeat IWB occurred in 11 members of 10 different families. Nine IWB were among male children in the families (p<.01). IWB was caused by weakly reactive p-24 bands in 9/11 family members. 2/34 cord sera exhibited IWB; neither child had IWB >6 months later; one child acquired IWB that was not present in cord serum. IWB occurred in 23% of low-risk adults in Huntington, WV.
Conclusion. IWB is common among persons at low risk for HIV in our city. There was no evidence of horizontal transmission of IWB in families or vertical transmission for mothers to children.

Th.A.P.89

INTERNATIONAL REGISTRY OF SEROCONVERTERS:

Biggar, Robert*; Goedert, J.*; Blattner, W*. (*National Cancer Institute, Bethesda, MD), and the Seroconverters Working Group.

Objective. To expand an ongoing registry of persons with documented HIV seroconversion in order to determine the natural history of HIV infection and compare the course of HIV in persons infected by different routes, in different geographic areas and at different times.
Background. The natural history of HIV will be best understood when the time of infection can be reliably established. Most investigators doing prospective studies have relatively few seroconverting subjects and enroll subjects of only one risk group. Thus, the ability of single cohorts to address critical natural history issues is limited.
Methods. We have established a registry of seroconverters by providing simple data forms to investigators engaged in prospective studies of groups at risk of AIDS. Essential data are identifying number (names not accepted in order to assure confidentiality), age, sex, risk group, dates HIV antibody tests were last negative and first positive, dates and types of anti-viral treatments (if any), last follow-up date, AIDS outcome by type. Summary reports will be prepared at NCI and shared with all participants.
Results. Results are presented elsewhere (See Time-to-AIDS among 816 Seroconverters, by the Seroconverters Working Group [Biggar]). So far 1115 seroconverters (between 1978 and 1988) have been registered by 38 investigators from the United States, Canada, Europe and Australia. Risk groups include homosexual men, hemophiliacs, i.v. drug users, blood recipients, and heterosexual partners.
NEW CONTRIBUTIONS WILL BE WELCOME. We would be pleased to answer questions and provide forms and guidance for investigators willing to participate.

Th.A.P.90

LACK OF CORRELATION BETWEEN NEUTRALIZING ANTIBODY TITERS AND CD4$^+$ DECLINE IN THE SAN FRANCISCO MEN'S HEALTH STUDY.

Sheppard, Haynes*; Hanson, C.**; Mikasa, L.**; Royce, R.***.
*California Public Health Foundation; **Viral and Rickettsial Disease Laboratory, Department of Health Services; **University of California, Berkeley, CA, U.S.A.

Objective. To determine the relationship between neutralizing antibody titer and the decline in CD4$^+$ cells in HIV disease.
Methods. A novel fluorescent micro-plaque reduction assay was used to measure the neutralizing antibody titer for 154 gay and bisexual men 30 months after entry into the San Francisco Men's Health Study. This assay employs a monolayer of the MT2 cell line formed by centrifugation through molten agarose in 96 well trays. The study population was composed of 120 seropositive asymptomatic individuals with >650 CD4$^+$ cells at entry (1984) and 34 seronegative controls. Of the seropositives, 56 continued to have >650 CD4$^+$ cells after 30 months while 64 showed a decline in CD4$^+$ cells. The relative neutralizing capacity is expressed as the reciprocal of the serum dilution at which 50% of the input plaque forming units are inhibited.
Results. All sera which were antibody negative by ELISA showed no neutralizing capacity at the lowest serum dilution (1:3). All positive sera had some capacity to neutralize prototype HTLV-III with a range of titers from 12-3378. The geometric mean titer for the group without CD4$^+$ decline was 432. The geometric mean titer for the group with declining CD4$^+$ cell numbers was 486. There was no statistical difference in the distribution of titers within the two groups.
Conclusion. This work suggests that there is little or no correlation between CD4$^+$ cell decline and the capacity to neutralize the prototype strain of HIV-1.

Th.A.P.91 THE EFFECT OF HEPATITIS B VIRUS VACCINATION ON T-CELL SUBSETS IN HIV-1 SEROPOSITIVE MEN IN THE BALTIMORE MACS

Odaka Nancy. Margolick J. Fox R. Muñoz A. The Johns Hopkins School of Hygiene and Public Health. Baltimore, MD. USA.

Objective To compare the effect of hepatitis B virus vaccination (HBVV) on T-cell subsets in HIV-1 seropositive(+) and seronegative(-) homosexual men. Methods Previously HBV seronegative HIV-1 + and - homosexual men in the Baltimore MACS either did or did not receive HBVV. Blood was drawn immediately prior to enrollment in the study (baseline) and every six months thereafter for analysis of T-cell subsets (CD4%, CD8%). Change(Δ) was defined as the difference between the baseline value and the most recent evaluation, with followup(F/up) ranging from 6 to 36 months.
Results

					CD4%		CD8%	
Group	HIV-1	HBVV	N	Mean F/up	Baseline Mean ± SD	Mean Δ per 6 mos	Baseline Mean ± SD	Mean Δ per 6 mos
1	-	-	112	32.6	48 ± 8.4	-0.4	27 ± 7.6	0.1
2	-	+	102	32.7	47 ± 8.6	-0.2	29 ± 8.1	-0.6
3	+	-	23	33.8	32 ± 8.7	-1.8^{a}	44 ±11.0	1.8^{a}
4	+	+	21	31.3	30 ±11.2	$-3.3^{a,b}$	37 ±10.4	$4.3^{a,c}$

a: $p < 0.05$ compared to group 1; b: $p=0.003$ compared to group 3; c: $p=0.007$ compared to group 3. The differences between groups 3 and 4 persisted after adjusting for baseline %CD4 and %CD8.
Conclusion These data suggest that HBVV may influence T-cell subset proportions in HIV-1 + individuals over time. Further followup of this and other populations is need to confirm this conclusion.

Th.A.P.92 INCREASED RATE OF HIV-1 ISOLATION AMONG INFECTED HOMOSEXUALS WITH LOW CD_4 COUNT

Homayoon Farzadegan, K. Qatsha, W. Hardy, D. Imagawa, M. Lee, C. Grovit, P. Gupta: A Report from the Multicenter AIDS Cohort Study (MACS), NIH, Bethesda, MD, U.S.A.

OBJECTIVE: To correlate variation in HIV-1 isolation with changes in immune status as determined by CD_4 count among HIV-1 seroconverters.
METHOD: One hundred and ninety-four seroconverted homo/bisexual men participating in a prospective study of the natural history of HIV-1 infection were studied for HIV-1 isolation and cellular immune status in three (MACS) Centers. Cocultivation with normal PHA-P stimulated PBMC's were monitored four weeks for HIV-1 replication utilizing P24 antigen capture.
RESULTS:

CD_4+/mm²	+/Total	%	CD_4+/mm²	+/Total	%
0 - 199	24/25	96	600 - 799	29/38	76
200 - 399	24/36	67	800 - 999	12/18	67
400 - 599	38/50	76	> 1000	13/27	48

The HIV isolation rate for participants with low CD_4 (< 200) was greater than those with high CD_4 (> 1000) count. The test for trend was statistically significant (Mantel-Haenszel chi square 9.4, $P=0.002$).
CONCLUSION: Declining CD_4 is associated with immune impairment. The association between lower CD_4 count and increased HIV-1 recovery may suggest that progression of HIV-1 infection is associated with a higher percentage of infected T-cells and more effective viral replication. Low CD_4 cell count is a significant predictor of HIV-1 isolation.

Th.A.P.93 INCREASED "VIRAL BURDEN" IN LATE STAGES OF HIV INFECTION.

Burke, D.S.*; Redfield, R.R.*; Fowler, A.**; Oster, C.*; and the Walter Reed Retrovirus Research Group *Walter Reed Army Inst. Res., ** SRA Technologies, Inc., Washington, D.C.,U.S.A.

Objective. To compare results of HIV isolation attempts from peripheral blood mononuclear cells (PBMC's) of early versus late stage patients.
Methods. PBMC's from 91 staged HIV seropositive patients were obtained from heparinized blood specimens by density gradient fractionation. $3x10^6$ and $3x10^5$ cells from each patient were inoculated into cultures of PHA and IL-2 stimulated normal donor target PBMC's. Culture fluids were monitored weekly for HIV p24 antigen.
Results.

		Positive		
Stage	# Total	≤ 7 days	> 7 days	Negative
Controls	19	0	0	19 (100%)
WR 1 - 2	41	11 (27%)	16 (39%)	14 (34%)
WR 3 - 5	40	27 (68%)	8 (20%)	5 (12%)
WR 6	10	10 (100%)	0	0

90% of HIV seropositive patients with decreased CD4 cell counts (less than 400 per mm3, stages 3 - 6) were culture positive, compared to 66% of early stage patients with normal CD4 counts. Cultures became positive more rapidly in patients with late stage disease.
Conclusion. HIV can be more frequently and more rapidly recovered from blood in the later stages of illness.

Th.A.P.94 GRAPHICAL DESCRIPTION OF HEMATOLOGICAL CHANGES AFTER HIV-1 SEROCONVERSION IN HOMOSEXUAL MEN.

Muñoz, Alvaro; Margolick J; Phair J;Giorgi JV;Rinaldo C, for the Multicenter AIDS Cohort Study (MACS), Bethesda, MD, USA.

Objective. Describe the multivariate distribution of hematological variables at different times from HIV-1 seroconversion. Methods. The 271 seroconverters observed in the MACS within 4 years of follow-up provided 1816 assessments of hematological values at different times from seroconversion from -1 to 3 yrs. Baricentric coordinates and contours of multivariate normal distributions estimated from the data were used to display the interactions between different variables. Results. The means and standard deviations of selected hematological variables according to the number of years from seroconversion were

	Years from HIV-1 Seroconversion				
	-1	0	1	2	3
Assessments (N)	192	445	517	443	220
ln(CD4/CD8)	0.49±0.46	0.24±0.57	-0.13±0.58	-0.37±0.69	-0.64±0.78
CD3-(CD4+CD8)(/µl)	10±120	17±129	39±100	66±103	52±105
Hemoglobin(g/dl)	15.44±1.10	15.38±1.09	15.23±1.20	15.06±1.15	15.07±1.17
Platelets (in K)	270±58	259±60	246±57	227±55	215±53

The CD4:CD8 ratio was negatively correlated with double negative cells (CD3-(CD4+CD8)), positively correlated with hemoglobin and had a consistently small correlation with platelets. Conclusion. Strong downward trends after seroconversion are apparent in CD4/CD8 and in platelets. CD4/CD8 and platelets are weakly correlated and have different prognostic information for AIDS. Changes in double negative cells and hemoglobin are systematic, but of small magnitude relative to their variability.

Th.A.P.95 SEROLOGIC EVIDENCE OF EPSTEIN-BARR VIRUS (EBV) REACTIVATION BEFORE AND AFTER HIV-1 SEROCONVERSION.

Rahman, Abid*; Kingsley, L.*; Rinaldo, C.*; Atchison, R.*; Ho, M.*; Breinig, M.*.
*University of Pittsburgh, Graduate School of Public Health, Pittsburgh, Pennsylvania, USA.

Objective. To evaluate the relationship between early HIV-1 infection and active/reactivated EBV infection based on serologic markers of EBV infection.
Methods. This nested case-control study included a group of homosexual/bisexual men who seroconverted to HIV-1 (n=49) referenced to matched controls (n=49) who remained seronegative to HIV-1 for 2 1/2 years. HIV-1 infection was documented by ELISA and confirmed by Western-blot assay. Immunofluorescence assays were used to determine IgG antibody titers to EBV-VCA, EBV-EA and EBNA.
Results. All 49 HIV seroconverters were seropositive to EBV (titer ≥ 1:5) while 47/49 (96%) of controls were seropositive to EBV. Antibody titers to EBV-VCA and EBNA did not differ significantly between cases and controls 6 months prior to the time of HIV-1 seroconversion for cases. Antibody titers to EBV-EA were significantly elevated ($p < .001$) among cases (Geometric mean titer GMT = 35) prior to HIV-1 seroconversion compared to controls (GMT = 7) and remained significantly elevated for 1 1/2 years post HIV-1 seroconversion. Four-fold or greater rises in VCA-IgG titers were strongly associated with HIV-1 seroconversion (odds ratio = 3.4; $p = .004$), indicating probable reactivation of EBV. Negative correlations were observed between the antibody titers to EBV-VCA and EBV-EA to CD4+ lymphocytes, while mean number of CD8+ lymphocytes were elevated in cases pre and post HIV seroconversion.
Conclusion. These results suggest that EBV reactivation is correlated with HIV-1 seroconversion and that evidence of a ≥ 4 fold rise in VCA-IgG is detected in a majority of HIV-1 seroconverters within 18 months. This may have implications regarding the role of EBV in the future pathogenesis of HIV-1 infection.

Th.A.P.96 CLINICAL PATTERN AND COURSE OF HIV INFECTION IN 29 PATIENTS WITH SEROCONVERSION

Brodt R., Staszewski S., Kindervater G., Kamps B., Gottstein A., Helm E.B.
Universitätsklinik Frankfurt, Zentrum der Inneren Medizin, Infektiologie, Th.-Stern-Kai 7, 6000 Frankfurt/M.,Federal Republic of Germany

Objective: To describe changes in immunological parameters and occurrence /course of clinical symptoms in patients (pts) with seroconversion (SC) of HIV antibodies.
Methods: During routine check-ups of ca. 3000 pts with risk for HIV infection between 1/1985 and 12/1988 at Frankfurt University Clinic, SC could be proved in 29 pts. All serum samples, positive and negative ones, were re-tested by means of ELISA, IFT, or WB. All 29 pts were followed up (physical examination, routine lab, lymphocyte subtyping).
Results: Mean intervall from last negative to first positive test was 180 ds (min. 10, max. 535 ds). Under the assumption of average time to SC being up to 40 ds, mean infection date was 40-220 ds before 1st positive test. In the course of SC, of 29 pts, 1 had meningo-encephalitis, 1 had generalized convulsions, 4 pts had exanthema, 10 symptoms of parainfluenzal bouts. Physical & immunological follow-ups (6-39mo after SC; mean: 19mo) showed that only 19 pts (31%) had non-pathological results; after 6-12mo, already 16 pts (55%) had an increase in CD8+ cell count, 4 pts (14%) a decrease in CD4+ cell count.
Conclusion: 2/3 of our patients presented with subclinical or manifest symptoms due to acute HIV infection. Further examinations will have to show whether different patterns of acute infection correlate with different long term courses.

Th.A.P.97 IMMUNOLOGIC ABNORMALITIES IN ANTI-HIV-1 NEGATIVE (-) AND ANTI-HTLV-I/II NEGATIVE AND POSITIVE (+) IV DRUG ABUSERS (IVDA) ON METHADONE.

Klimas, Nancy* **, Blaney, N.**, Morgan, R.**, Simoneau, J.* and Fletcher, M.* **, *VA Medical Center and **Univ. of Miami Center for Biopsychosocial Study of AIDS, Miami, Florida, USA.

Objectives To determine the effects of HTLV-I/II infection and drug use on immune function in an AIDS risk group.
Methods Immunologic status was determined on 9 men who were anti-HTLV-I/II (+) and 20 men who were anti-HTLV-I/II (-), all of whom were anti-HIV-1 (-) and all of whom were IVDA on methadone maintenance enrolled in an outpatient treatment unit, and on 38 age and sex matched non-drug abusing controls. The immunologic tests were clustered into 6 groups and overall, non-parametric multivariate analyses (Kruskal-Wallis one-way analysis based on ranks) were done. Within groups, individual Kruskak-Wallis tests were done on each measure.
Results No significant differences were seen either in groups of immunologic measures, or in individual measures between the anti-HTLV-I/II (+) and (-) drug abusers. Significant differences between the drug users and controls were observed for natural killer (NK) cell cytotoxicity, T cell subsets, lymphoproliferative assays and immunoglobulins. NK cell subsets and B cell subsets were not significantly different. For T cell subsets, significant elevations were observed in the number of CD4 cells expressing CDw29, the helper subset, in CD8 cells and CD8+I2+ cells and in CD2+Tal+ cells. IgG and IgM were elevated. Lymphocyte proliferation in response to pokeweed mitogen stimulation was 4-fold lower in the methadone group. NK cell activity was less than half the control value.
Conclusion The immunologic abnormalities, perhaps due to IV drug use and/or methadone, observed in this AIDS risk group, may increase susceptibility to HIV and contribute to HIV related disease progression after infection. There were no immunologic differences observed between the anti-HTLV-I/II (+) and (-) drug users. (supported by NIMH P50-MH/DA-42455).

Th.A.P.99 AJUSTEMENT DE MODELES CHRONOLOGIQUES AVEC RUPTURES SUR UNE FONCTION DISCRIMINANTE.

Prum Bernard*, Picard D.*, Rozenbaum W.**, [illegible] D.*, Guihenneuc C.*
* Université Paris V; ** Hôpital Rothschild, Paris, France.

Objectifs. Ajuster une fonction discriminante des états cliniques sur les données biologiques qui ait valeur prédictive.
Méthodes. Nous avons traité un dossier de 200 malades suivis pendant 2 à 5 ans et examinés au moins 5 fois. Chaque examen fournit un état clinique codé de 1 à 9 et un certain nombre de données biologiques parmi lesquelles nous avons retenu les nombres de globules blancs, de lymphocytes, de T4 et de T8 et les taux d'IgA, d'IgG, et de la Bêta 2 microglobuline (B2M). Une analyse discriminante des états cliniques fondée sur les données biologiques est faite, puis plusieurs modèles chronologiques sont ajustés sur la première fonction discriminante mesurée à plusieurs instants sur un même individu.
Résultats. Nous indiquons dans le tableau les coefficients canoniques normalisés (CCN) de la première fonction discriminante pour chaque facteur, ainsi que l'écart type de ce facteur (SD).

	CCN	SD
B2M	0,409	195
Globules blancs	- 0,434	2077
Lymphocytes	- 0,105	946
T4	- 0,013	377
T8	0,019	553
IgG	- 0,303	72
IgA	0,780	20

Les rôles principaux sont donc joués par IgA, GB et B2M. Cette fonction présente en outre l'intérêt d'être fonction croissante du diagnostic. Une forte non stationnarité temporelle exclut les modèles ARMA simples, ce qui conduit à ajuster des modèles permettant une possibilité de rupture estimant pour chaque patient la date de rupture.

Th.A.P.101 LACK OF ASSOCIATION OF T-CELL SUBSETS WITH CONTINUING INTRAVENOUS DRUG USE AND HIGH RISK HETEROSEXUAL SEX, INDEPENDENT OF HIV INFECTION AND DISEASE.

Schoenbaum EE, Hartel D, Selwyn PA, Davenny K, Gerald Friedland, Klein RS.
Montefiore Medical Center, Albert Einstein College of Med., Bronx, N.Y., USA.

Objective. To examine the relation of T-cell subsets to continuing drug use and high risk heterosexual sex in intravenous drug users with known HIV serostatus.
Methods. From 1985-88 701 methadone maintained intravenous drug users (IVDUs) enrolled in a natural history study of HIV infection had semi-annual physical exams, interviews for demography, medical, drug use and sexual history and tests for HIV antibody (Ab) and T-cell subsets. Number of injections (INJ), injections in shooting galleries (SG-INJ), IVDU heterosexual sex partners (SEX) and duration and severity of HIV related illness (AIDS, oral thrush, constitutional symptoms) from enrollment to last visit were examined in relation to CD4 count and CD4/CD8 at last visit.
Results. Table of mean CD4 counts and CD4/CD8 by continuing INJ and SEX is shown.

	HIV Ab + (n=171)				HIV Ab - (n=243)			
	INJ	No INJ	SEX	No SEX	INJ	No INJ	SEX	No SEX
CD4	564	467	525	512	1180	1253	1201	1248
CD4/CD8	.59	.57	.62	.53	1.52	1.70	1.58	1.69

Regression analysis in HIV Ab + revealed no association of CD4 count and CD4/CD8 with INJ (p=.60), INJ-SG (p=.35), SEX (p=.13) but strong association with duration of HIV related illness (p=.04). In HIV Ab - regression analysis revealed no association with INJ, INJ-SG or SEX.
CONCLUSION. This study suggests that high risk drug and sex behavior do not influence T-cell subsets independent of the presence of HIV infection and severity and duration of HIV-related disease.

Th.A.P.98 MYCOBACTERIAL INFECTIONS IN MASSACHUSETTS AIDS PATIENTS

Makarewicz, L.*; Day, J.*; Kunches, Laureen*; Heinze-Lacey, B.**; Oddleifson, S.**; Hofenson, L.* et al.
Massachusetts* and Boston** AIDS Surveillance Program, Boston, MA, USA.

Objective: To compare the demographic characteristics of AIDS patients who have M. tuberculosis (MTB), M. avium intracellulare (MAI) or NEITHER.
Methods: In 1/99, reported resident AIDS cases (CDC defined) in the statewide case registry that had been diagnosed through 6/30/88 were analyzed. State TB Registry cases (since 1982) and culture reports from the State Mycobacterium Reference Laboratory (since 1985) were matched with the AIDS registry.
Results: Of 1545 resident cases, 1330 (86%) had NEITHER, 74 (5%) were classified as MTB (including 2 with both MTB and MAI), and 141 (9%) had disseminated MAI. Case fatality rates for MTB, MAI and NEITHER were 51%, 77% and 50%, respectively. Overrepresentation of non-whites and heterosexually transmitted cases (including 96% foreign born) was seen for MTB ($p < 0.001$).

	Race		Transmission Group		
	White	Non-white	Homo/bisexual	Heterosex.	Not Sexual
MTB	35%	65%	30%	35%	35%
MAI	68%	32%	63%	1%	36%
NEITHER	72%	28%	64%	4%	32%

Conclusion: In Massachusetts, MTB in AIDS occurs predominantly among non-white, foreign born adults acquiring HIV through heterosexual contact. However, MAI patients are demographically similar to those with NEITHER, except for a higher case fatality rate. These findings suggest that MAI is a random event indicative of current immunocompromised status whereas MTB reflects immunosuppression in the context of prior MTB exposure.

Th.A.P.100 DO CLINICAL HERPES SIMPLEX VIRUS (HSV) AND VARICELLA-ZOSTER (VZV) INFECTIONS ACCELERATE HIV-1-INDUCED IMMUNODEFICIENCY?

Kaslow, Richard A.*; VanRaden, M.; DeLoria, M.; Zeger, S.; Dudley, J.; Alwood, K.; Wolinsky, S.; Ho, M. and the Multicenter AIDS Cohort Study (MACS). *Bethesda, MD, U.S.A.

Objective: In view of reports that herpesvirus products promote HIV-1 replication (JID, 1988, 157:508), we sought to determine whether attacks of HSV and VZV infection accelerate immunodeficiency in HIV-1-seropositive men.
Methods: HIV-1-seropositive AIDS-free homosexual participants reporting clinical HSV or VZV histories during 6-month follow-up periods were compared to HIV-1-seropositives reporting neither HSV nor VZV. Rates of loss of $CD4^+$ cells were compared for the intervals before, around and after the recognition of HSV or VZV symptoms. Overall declines in $CD4^+$ cell count were compared in clinically affected and unaffected men.
Results: During the study period, of 173 men reporting the first attack of HSV in at least a year, 75 had the first attack ever; none ever had zoster. Another 78 men reported the first attack of zoster. For HSV the mean $CD4^+$ cell count declines were 36 in the 6 months before, 32 in the 6 months around, and 26 in the 6 months after the selected attack. For VZV the mean declines were 41, 27 and 39 before, around and after the attack, respectively. Declines before and after attacks did not significantly differ. Overall loss of $CD4^+$ cells during the period was slightly greater in affected (HSV=94, $p=0.03$; VZV=107, $p=0.17$) than in unaffected men (None=59).
Conclusion: We found weak evidence that HIV-1-induced immunodeficiency progressed faster in men with clinically expressed HSV and VZV infection.

Th.A.P.102 PROGRESSION OF HIV DISEASE IN INTRAVENOUS DRUG USERS

Gorter, Robert*, Kocurek, K.*, Brodie, B*, Bacchetti, P.*, Ross, E.*, Moss, A.R.*, *University of California, San Francisco, California, USA.

OBJECTIVE: To evaluate progression of HIV+ IVDUs in San Francisco.
METHODS: 120 HIV+ IVDUs recruited from drug treatment programs were evaluated clinically and for laboratory markers and followed at SFGH. Data were compared with HIV+ gay men followed in the SFGH cohort.
RESULTS:

	IVDU		SFGH Cohort		
	baseline	12 month	baseline	12 month	36 month
Median CD4	421	353	626	551	428
CD4 < 200	12%	28%	3%	4%	18%
Median B2M	3.2	3.6	2.7	2.6	2.8
B2M > 3.0	60%	69%	40%	33%	37%
P24-Ag+	9%	5%	16%	18%	20%

45% of IVDUs were symptomatic at baseline, comparable to 41% of gay men at 3 years of follow-up or 6 years of infection. 4/120 IVDUs have developed AIDS over a median 1 year. IVDUs had a greater yearly increase in Beta-2 microglobulin (B2M) than gay men (p=.003) and comparable decline in CD4 count.
CONCLUSIONS: Differences at baseline and in B2M may be due to a longer duration of infection, a higher rate of progression or a more immunocompromised state in IVDUs. 12% of drug users at baseline were eligible for zidovudine, but only one was receiving it. HIV infected IVDUs recruited in San Francisco are sick, appear to be progressing rapidly and are underserved.

Th.A.P.103 A RETROSPECTIVE FOLLOW-UP STUDY OF MORBIDITY AMONG HIV INFECTED YOUNG ADULTS PRIOR TO A DIAGNOSIS OF HIV INFECTION: A "TRUE" NATURAL HISTORY STUDY

McNeil, J.; Renzullo, Philip; Brundage, J.
Walter Reed Army Institute of Research, Washington, DC, USA.

Objective. To investigate trends in morbidity in 1329 HIV infected US Army personnel, prior to being diagnosed with HIV infection. .
Methods. A case-control study was conducted with four HIV-Ab negative controls matched to each HIV-Ab positive case. Hospitalization histories were obtained for all individuals from an automated database of discharge diagnoses reported from all Army hospitals. Diagnoses associated with AIDS were excluded from the analysis.
Results. Hospital admission Rate Ratios (RR) and 95% Confidence Intervals (CI) are presented for 8 years prior to HIV infection diagnosis in cases.

YEARS PRIOR TO HIV INFECTION DIAGNOSIS

	8	7	6	5	4	3	2	1
RR	1.63	1.25	1.26	1.46	1.56	1.80	2.01	1.54
CI	1.23,2.15	0.94,1.66	0.96,1.63	1.14,1.88	1.25,1.94	1.48,2.19	1.68,2.39	1.30,1.81

Six to 8 years prior to HIV infection diagnosis, significant excess morbidity was accounted for by unspecified drug abuse, hepatitis B, and intracranial injuries. One to 5 years prior to HIV infection diagnosis, significant excess morbidity was seen in 9 diagnoses that were infectious in nature (e.g. enlarged lymph nodes, latent syphilis, genital warts), anal/rectal abscesses, and drug abuse.
Conclusion. Significant excess, non-AIDS related morbidity exists as far back as 8 years prior to HIV infection diagnosis in individuals currently infected with HIV. Studies of this nature, which are uninfluenced by subjects' knowledge of HIV infection, accurately describe and quantify morbidity from acute and early-stage HIV infection, as well as from high risk behavior.

Th.A.P.104 HIV INFECTION INCREASES THE FREQUENCY AND SEVERITY OF PAPILLOMAVIRUS INDUCED CERVICAL CYTOLOGIC ABNORMALITIES

Feingold, Anat R.; Vermund, S.H.; Burk, R.D.; Kelley, K.F.; Schrager, L.K.; Klein, R.S.; et al.
Montefiore Medical Ctr/Albert Einstein College of Medicine, Bronx, NY, USA.

Objective. To compare frequency and severity of cervical dysplasia in women with and without HIV, human papillomavirus (HPV) infection and other STD's.
Methods. Female intravenous drug users (IVDU) and heterosexual partners of IVDU's underwent a standardized questionnaire and gynecologic exam including cervical cytology. Cervicovaginal cells were collected by lavage and evaluated for HPV by Southern blot. HIV status and syphilis were assessed by serology; gonorrhea, chlamydia and HSV by endocervical culture.
Results. Abnormal cytology (Pap grade II - IV) was found in 85% (11/13) of HIV+/HPV+ women, 6% (1/16) of HIV+/HPV- women, 29% (2/7) of HIV-/HPV+ women, and 14% (3/22) of HIV-/HPV- women.

HIV	HPV	Pap: II, III, IV	Pap: I
+	+	11	2
+	-	1	15
		OR=82.5	

HIV	HPV	Pap: II, III, IV	Pap: I
-	+	2	5
-	-	3	19
			OR=2.5

[Mantel-Haenszel Summary Odds Ratio = 11.9, 95% c.i.: 2.1, 49.2]

Of the 5 grade III and IV Pap smears, 4 were in HIV+/HPV+ and 1 was in a HIV+/HPV- woman. Smoking, sociodemographic characteristics and other STD's were not associated with abnormal cervical cytology in this population.
Conclusion. Cervical cytologic abnormalities were associated with HPV infection and occurred with an increased frequency and severity in the presence of HIV infection. These data suggest that HIV infection exacerbates HPV mediated cervical cytologic abnormalities.

Th.A.P.105 EARLY HIV-1 INFLUENCE ON MALIGNANCIES

Transfusion Safety Study Group* represented by Operskalski, Eva A.**.
*Participating institutions, New York City, Miami, Detroit, Seattle, San Francisco, Los Angeles, USA, **University of Southern California, Los Angeles, California, USA.

Objective. To evaluate whether persons with HIV-1 infection are at increased risk for developing malignancies other than those included in the definition of AIDS (Kaposi's sarcoma and non-Hodgkin's lymphoma (NHL)).
Methods. In a longitudinal study of transfusion-associated HIV-1 infection, data are collected on malignancies among anti-HIV-1(+) blood donors, recipients of blood components, persons with congenital hematologic disorders (CHD), and anti-HIV-1(-) controls for each group. Excluded in the present analyses were non-melanomatous skin cancers.
Results. The number and percent of enrolled subjects with malignancies diagnosed since 1979 or, for recipients, since the index transfusion are:

	anti-HIV(+)				anti-HIV(-)	
Subject group	Subjects	KS	NHL	Other CA	Subjects	Other CA
Donors	148	4 (3%)	0 (0%)	1 (1%)	153	0 (0%)
Recipients	121	0 (0%)	4 (3%)	4 (3%)	73	3 (4%)
CHD	679	1 (0%)	8 (1%)	1 (1%)	871	7 (1%)
Household/sexual	26	0 (0%)	0 (0%)	0 (0%)	927	15 (2%)

Conclusion. Within the period of present observations, HIV-1 infection does not appear to have increased the risk of malignancy other than KS and non-Hodgkin's lymphoma.
(Sponsored by Contract No. NO1-HB-4-7003 of the National Heart, Lung, and Blood Institute.)

Th.A.P.106 AIDS AMONG HIV-1 INFECTED RECIPIENTS IN RELATION TO ITS OCCURRENCE IN THEIR SPECIFIC DONORS

Transfusion Safety Study Group* represented by Stuart, Marla**.
*Participating institutions, New York City, Miami, Detroit, Seattle, San Francisco, Los Angeles, USA, **University of Southern California, Los Angeles, California, USA.

Objective. To determine if AIDS was more likely to develop in recipients of anti-HIV (+) components from donors whose infection was known to have progressed to AIDS.
Methods. The Transfusion Safety Study retrospectively tested donor sera collected in late 1984 and early 1985 in 4 areas with a high AIDS prevalence. Recipients of blood components from anti-HIV (+) donors and the donors of these components were enrolled in a longitudinal study. There were 37 donors under observation whose components were given to 50 recipients who survived and have been followed at 6-month intervals.
Results. Two of the donors have developed AIDS since their donation. Among their 7 recipients, 1 (14%) has developed AIDS. Among the 43 recipients whose 35 donors have not developed AIDS, 5 developed AIDS (12%). (Fisher's exact test, 1-tailed, p = 0.6.)
Conclusion. The progression of HIV-1 infection to AIDS in a recipient is independent of progression in the donor. Thus, clinical expression appears to be more characteristic of the host rather than the strain of virus.
(Sponsored by Contract No. NO1-HB-4-7003 of the National Heart, Lung, and Blood Institute.)

Th.A.P.107 PSORIASIS AS A CAUSE OF "FALSE-POSITIVE" HIV WESTERN BLOTS: DETECTION OF GAG-SPECIFIC ANTIBODIES IN VIRTUALLY ALL CASES

Schüpbach, Jörg*; Baumgartner, A.*; Bruckner-Tuderman, L.**,
* Swiss National Center for Retroviruses, Institute of Immunology and Virology, University of Zurich, Zurich, Switzerland
**Department of Dermatology, University Hospital, Zurich

Objective. To look for causes of indeterminate HIV Western blots (WB)
Methods. Sera from 54 psoriasis patients and 52 blood donors were tested for antibodies (AB) to HIV-1 and HTLV-1 by recombinant EIA, ENVACOR confirmatory assay (both ABBOTT), SERODIA ATLA, and WB, with serum diluted 1:25 and WB kits (DuPont) pre-screened for maximal sensitivity to gag AB. Competition WB was done to assess specificity and avidity of reactive AB.
Results. All sera were negative by HIV-1 EIA, ENVACOR, and SERODIA ATLA. On HIV-1 WB, 98% of psoriasis (44% of controls) had reaction with at least one HIV protein, with the following distribution: p24 96% (33), p17 44% (19), p55 13% (2), p66/51 in 4% (0). Six % (11) reacted faintly with HTLV-1 gag. Specificity assays showed that the AB reacted with viral, and not cellular, antigens, but were of lower avidity than those of HIV-positive controls.
Conclusion. The results indicate that some indeterminate WB in individuals not exposed to HIV are associated with psoriasis and suggest that such patients have been exposed to antigens related to HIV-1, but not HTLV-1. The results support a retroviral association of psoriasis, as suggested by the demonstration of retrovirus-like particles in psoriatic lesions (Dalen et al., Acta Path Microbiol Immunol Scand B91:221,1983) and the demonstration of psoriasis-like lesions in HIV infection of humans and transgenic mice.

Th.A.P.108 DOUBLE POSITIFS WESTERN BLOT VIH1 ET VIH2 DISCRIMINES A L'AIDE DE PEPTIDES SYNTHETIQUES

SANJUAN A., COT M.C., DELAGNEAU Jean François
Diagnostics Pasteur, Marnes, France

Objectif:Déterminer l'intérêt de peptides synthétiques dans le diagnostic différentiel des infections à VIH.
Méthodes : Une étude d'échantillons présélectionnés a été menée dans les laboratoires suivants : Hôpital C.Bernard (F.Simon); Hôpital St Louis (F.Ferchal); Institut Pasteur (S.Chamaret); INTS (AM.Couroucé); CRTS Lille (M.Maniez-Montreuil, F.Decamp-Chevalier); CTS Versailles (L.Noël); CTSA (A.Blanchart de Vaucouleurs).
34 échantillons double séropositifs (présence d'anticorps dirigés contre les protéines du VIH1 et du VIH2, dont les protéines d'enveloppe) en Western Blot (New LAV BLOT I(®), New LAV BLOT II(®), ont été testés à l'aide de deux peptides synthétiques (Genetic Systems, USA) mimant un épitope immunodominant de la glycoprotéine transmembranaire : du VIH1 pour le peptide 39 (RILAVERYLKDQQLLGIWGCSGKLIC), du VIH2 pour le peptide 41.2.1 (NVTAIEKYLQDQARLNSWGCAFRQVC) (PEPTI-LAV 1.2)(®). - (®) Diagnostics Pasteur
Résultats :

Échantillons n = 34	Peptide 39	Peptide 41.2.1	
6	++	-	Discriminés 30/34 = 88,2 %
10	-	++	
3	+	-	
11	-	+	
4	+	+	Non discriminés 4/34 = 11,8 %

Conclusion : Si le New LAV BLOT I et le New LAV BLOT II permettent de détecter les anticorps anti VIH1 et anti VIH2 avec une grande sensibilité, des réactions croisées sont enregistrées. Le PEPTI-LAV 1.2 permet de différencier les sérologies VIH1/VIH2 pour 88,2% des cas testés. Les 4 cas non discriminés sont d'origine africaine ou antillaise. Les données de la littérature concernant les cas de double infection en Côte d'Ivoire et la spécificité des 2 peptides utilisés tendent à renforcer l'hypothèse d'une double infection.

Th.A.P.109 PCR SUBTYPING OF HIV INFECTIONS EXHIBITING REACTIVE SEROLOGIC RESPONSES TO HIV-1 AND -2

Rayfield M*, Ou C-Y*, Kreta JW*, Odehouri K**, Heyward WM*, Schochetman G*, et al. *AIDS Program, CDC, Atlanta, GA, USA; ** Projet Retro CI, Abidjan, Cote d'Ivoire

OBJECTIVE: Use of the polymerase chain reaction (PCR) to subtype HIV infections in patients expressing broad serologic responses to HIV-1 and -2.
METHODS: Seroreactive patients from North America and West Africa were subgrouped by a comparative analysis of their Western blot (WB) banding patterns and reaction in type-specific peptide EIAs (PEIA). Peripheral mononuclear cells from 16 persons were evaluated in PHA-stimulated cocultures and screened for proviral sequences with type-specific primers and probes for HIV-1 and -2 by selective DNA amplification using PCR.
RESULTS: Immunologic findings indicated that 3 sera were HIV-1 specific, 2 were HIV-2, and 11 reactive to HIV-1 and -2. PCR analysis confirmed the HIV-1 and -2 subgroupings and further segregated the dual reactive patients into 11 HIV-1 only, 4 HIV-2 only and 1 mixed HIV-1 and -2 infection. This mixed infection was confirmed by hybridization of type-specific probes to proviral DNA amplified with a primer set common to HIV-1 and-2. While PCR often indicated a single virus type, 3 patients remained equally reactive by all serologic parameters (arguably some mixed infections may fall below limit of sensitivity for PCR).
CONCLUSIONS: PCR is a definitive adjunct in subtyping whenever comparative analysis of EIA, PEIA and WB findings alone are insufficient. Further, genetic subtyping via PCR reveals that, while broad serologic responses may be elicited by either HIV-1 or -2 singularly, mixed HIV infections do occur.

Th.A.P.111 DETECTION OF HIV-1 FROM NEEDLES DISCARDED BY I.V. DRUG USERS IN ZURICH AND BASEL USING POLYMERASE CHAIN REACTION. ASSESSMENT OF IN VITRO INFECTIVITY.

Raineri, Ines*; Senn, H.P.**; Scheidegger, C.***; Hornung, R.****; Lüthy, R.*; Vogt, M.*
*Division of Infectious Diseases, Dept. of Medicine and **** Institute for Social and Preventive Medicine, University Hospital Zurich; ** Institute for Medical Microbiology and *** Dept. of Medicine University Hospital Basel, Switzerland

Objective. In Zurich and Basel HIV-1 seroprevalence rates among regular iv drug users are approx. 60 percent. To avoid needle sharing, injection equipment is provided free or at low cost. Accidental needle stick exposures have occurred frequently via neglectfully discarded needles and the risk for HIV infection has never been determined in this specific setting.
Methods. Discarded syringes and needles were collected in Zurich (n=11) and Basel (n=12) and dried contents from needles only were processed. HIV-DNA was detected by PCR using cloned Taq-Polymerase (Ampli-Taq) and an oligonucleotide primer pair located in the pol gene. Amplified DNA was dotblotted and hybridized to a ^{32}P-labeled oligonucleotide probe. Additionally, HIV-1 cultures were performed from collected needles (n=3) and from 25 needles artificially filled with blood from HIV-1 seropositive patients. These needles first remained at room temperature for 0, 1, 4, 24, 48 hr and were cultured thereafter.
Results. HIV-DNA was detected in 2 of 11 collected needles from Zurich and in 2 of 12 needles from Basel, respectively. We were not able to culture HIV-1 from collected needles. Time exposure studies revealed that target lymphocytes could only be infected with needles exposed to room temperature for 4 hr or less.

Conclusion. HIV-1 DNA can be detected in discarded needles of intravenous drug users. In vitro infectivity of contaminated needles diminishes in a time dependent manner.

Th.A.P.113 Antibodies to HIV-1 gp120 Env epitopes correlate with uninfected status of the children born to seropositive mothers

Rossi, Paolo I**; Moschese V*; Broliden P.A.**Ljunggren K.*Jondal M*; Wahren B** and Wigzell H.*
* Dept. of Immunology,Karolinska Institutet, Stockholm, Sweden, ** Dept. of Virology,SBL, Stockholm,Sweden, *Dept. of Pediatrics, II University of Rome, Rome,Italy.

Objective. To analyse the protective and/or predictive value of anti HIV epitope maternal and transferred antibodies in children born to HIV infected mothers.
Methods. A retrospective analysis included newborn sera of 33 infants whose infected or uninfected clinical outcome was known. A prospective study included sera collected at delivery from 11 mother-child pairs whose infant clinical status has been then monitored for about 15 months. Peptide ELISA assay was performed using as antigen small linear peptides containing 15 aa and overlapping 10 aa representing the major immunodominant regions of env and gag encoded regions. Recombinant protein were also used and included, PB1,p2av9,p121 and p24/15.
Results. 31 % of newborn sera from uninfected at-risk children were found to contain antibodies to gp120/C57 (a.a. 324-338) peptide mapping the c-terminal part of the so called hypervariable loop of PB1 region. No such reactivity was present in sera from infected newborn. When mother-child pairs were analysed the same skewed reactivity pattern was observed with a highly significant seroprevalence(86 %) in sera of mothers giving birth to uninfected children. Analysis of contiguous aa sequences of the loop (gp120/C58, gp120/C51) also showed clustered reactivity to this group of individuals.
Conclusions. Presence of antibodies against the cysteine residue-containing sequences of the putative hypervariable loop of pB1 region in the sera of HIV infected mothers seems to be associated to uninfected outcome of the pregnancy.

Th.A.P.110 CONFIRMATION AND VIRUS TYPING USING PCR ANALYSIS OF HTLV-I ELISA REACTIVE SAMPLES

John J. Sninsky*, J.Lipka**, D. Kellogg*, N. McKinney*, S. Fong**, B. Poiesz***, S. Kwok* * Department of Infectious Diseases, Cetus Corporation, Emeryville,CA **Stanford University Blood Bank, Palo Alto, CA *** Suny, Syracuse NY

Objective. ELISAs are currently used to screen blood and blood products for the presence of HTLV-I. Confirmatory assays employing the Western blot procedure appear to have compromised sensitivity. In addition, because of cross reactivities of antibodies to the cognate HTLV-I and -II antigens, distinction between the two viruses is difficult. Method. Peripheral blood mononuclear cells were isolated from platelet fractions of 16 HTLV-I ELISA positive and 3 ELISA negative individuals. DNAs were initially analyzed with two different primer pairs and probes that amplify and detect either or both HTLV-I and -II. One primer pair/probe system amplifies and detects a region of tat of both viruses. The second primer pair amplifies a conserved region of pol of both viruses. Both group - specific as well as type-specific probes are available for this region. To confirm the presence of either proviral DNA, type-specific primers and probes were used.
Results. Of the 19 coded samples analyzed by PCR, two were positive with each of the two primer pairs that amplify and detect HTLV-I and -II. When type-specific probes were used, both samples were found to harbor HTLV-II. The presence of HTLV-II was confirmed with type-specific primers and probe. One of the two samples found positive for HTLV-II was confirmed positive by HTLV-I Western blot analysis since numerous viral antigens were recognized. The second sample had only a p24 band. Fourteen samples with indeterminate Western-blot patterns (either p19 or p28 only) were negative by PCR. The three HTLV-I ELISA negatives were negative by PCR.
Conclusion. PCR be used to differentiate between HTLV-I and -II infections and serve as a confirmatory test.

Th.A.P.112 A COMPARISON OF IFA AND EIA IN DETERMINING HTLV I SEROPREVALENCE IN THE IVORY COAST

Verdier, M.**; Anderson, E.*; Sangare, A.***; Canavaggio, Michel*; Denis, F.** and Glusic, W.* *Abbott Laboratories, North Chicago, IL 60064 USA, **Centre Hospitalo-Universitaire, Limoges, France ***Institut Pasteur Abidjan, Ivory Coast

OBJECTIVE. To compare the sensitivity and specificity of two different indirect immunoassays, EIA and IFA in detecting HTLV I seropositive subjects.

METHODS. Serum was collected from 2241 individuals belonging to 4 regions of the Ivory Coast; the coast, the center and the Eastern and Western borders. Samples were tested for antibody to HTLV I by both EIA and IFA. Samples repeatably reactive by either technique were confirmed for the presence of antibodies to HTLV I by Western blot and SDS-PAGE RIPA.

RESULTS. 71 (3.7%) and 170 (7.6%) samples were repeat reactive by EIA and IFA respectively. 36 of these samples were confirmed to contain anti-HTLV I antibodies. The EIA detected all of the confirmed samples while the IFA missed two. The highest rates of HTLV I infection were found in the coastal and central areas (1.96% and 3.23%, respectively) compared to the Eastern and Western borders (0.63% and 0.79%) of the Ivory Coast.

CONCLUSION. In this study, the EIA proved more sensitive and specific than the IFA. Clusters of HTLV I infection were present in the central and coastal regions of the Ivory Coast.

Th.A.P.114 STRAIN-SPECIFIC DNA PROBES TO STUDY THE EPIDEMIOLOGY OF HIV INFECTION

Ou, Chin-Yih.; Moore, J. L.; Robbins, K.; Villamarzo, Y.; Horsburgh, Jr. C. R.; Jason, J.; Evatt, B.; Schochetman, G. et al. Centers for Disease Control, Atlanta, GA. 30333

Objective. To study the transmission and evolution of HIV using strain-specific DNA probes.
Methods. A DNA primer pair was used to amplify a 320 bp envelope segment of HIV directly from lymphocyte DNA of infected persons by polymerase chain reaction (PCR). The amplified DNA includes two highly variable regions, V4 and V5 and a constant region, C3. Amplified DNAs were molecularly cloned and their nucleotide sequences determined. Based on the sequence information, strain-specific DNA probes were developed to study the presence of individual HIV strains in infected populations.
Results. Comparison of HIV sequences from a homosexual man from Boston (person A) and a hemophilic man from Philadelphia (person B) revealed the presence of a major genetic diversity in the V4 region. Strain-specific DNA oligomers were used to differentiate HIV strains by DNA hybridization. Among 20 homosexual men tested from the Boston area, a DNA probe derived from person A specifically identified a lymphocyte specimen from the same person collected 5 months later and two specimens from his sexual partner. Among 19 homosexual men tested from the San Francisco area, the same probe identified specimens from 4 homosexual men. A DNA probe derived from person B detected the presence of homologous HIV strains in 3 of the 5 hemophilic men who received the same lot of HIV contaminated antihemophilic factor.
Conclusion. We have developed a novel approach to study the transmission and evolution of individual HIV strains. This technology will play an important role in our understanding of the spread of HIV through the population.

Th.A.P.115 THE ESTABLISHMENT OF A ROUTINE SURVEILLANCE SYSTEM FOR DETECTING PREVALENCE OF HIV INFECTION IN SCOTLAND

David J Goldberg, J Emslie, C Guthrie, & D Reid
Communicable Diseases (Scotland) Unit, Ruchill Hospital, Glasgow, U.K..

INTRODUCTION & OBJECTIVE: Excluding blood donors, between 20,000 and 30,000 persons are tested for HIV each year in Scotland. Till very recently however, only infomration on those testing positive was recorded by the CD(S)U. To enable greater interpretation of seropositive data, it was decided to establish a national HIV surveillance system which would provide information not only on persons testing seropositive, but also on those testingseronegative.
METHODS: During 1988, a computerised network connecting the CD(S)U to all major HIV virology testing centres in Scotland was set up. In addition, a standard HIV laboratory request form, appropriately designed to encourage the documentation of details concerning: 1. Patient reference, 2. Referral source, 3. Reason for testing, 4. Transmission category, 5. Clinical information and 6. Additional information, was distributed to all clinicians working in hospitals and general practices throughout the country. Epidemiological information on all HIV specimens tested at these centres is entered onto laboratory computer terminals and from there, details uncoupled from patient identification are transmitted by telephone modem to a central database at the CD(S)U for collation and analysis.
RESULTS & CONCLUSION: The system started to function from 4th January, 1989. Summarised data on approximately 10,000 records will be presented to illustrate the system. We also describe how such a system was developed and discuss the difficulties we encountered in trying to establish it.

Th.A.P.117 COMPARISON OF THE SENSITIVITY OF VARIOUS ENZYME AND SUBSTRATE SYSTEMS FOR WESTERN BLOT ASSAY

Sam, Shirley W; Yap, [illegible] and Chan, L
Diagnostic Biotechnology (Pte) Ltd, Singapore

The conventional Western Blot (WB) assay is widely used for the confirmation of HTLV-I infection. However, as the WB assay is relatively insensitive in detecting antibodies to envelope proteins (gp46, gp61) other methods such as radioimmunoprecipitation (RIP) analysis and virus isolation have been used for more accurate confirmation. As such techniques are generally not available in most laboratories, there is a need to increase the sensitivity of the conventional WB system.
Objective: To evaluate the use of various enzyme and substrate systems to maximize the sensitivity of the conventional WB for HTLV-I infection.
Methods: Substrates for the horseradish peroxidase enzyme, diaminobenzidine (DAB) and Indophane (IND) were compared to 4-chloro-1-naphthol (4CN), the substrate widely used in commercial HIV-1 and HTLV-I Western Blot kits. An alternative enzyme and substrate system, alkaline phosphatase and 5-bromo-4-chloro-3-indolyl-phosphate / nitroblue tetrazolium (BCIP/NBT) was also evaluated. The sensitivity of the various systems were compared using: 1) Serial dilutions of anti-HTLV-I sera, and 2) Sera classified as indeterminate for HTLV-I infection by commercial HTLV-I WB kits.
Results: The DAB, IND and BCIP/NBT systems were consistently and repeatedly more sensitive than 4CN by a four to eight-fold serial dilution of positive sera. Sera (7) confirmed positive for HTLV-I infection by RIP assays but indeterminate by conventional HTLV-I WB were confirmed positive when the other systems were used. The sensitivity of detection of these systems correlated with results from RIP assays. Data from more HTLV-I indeterminate sera will be presented. It is thus possible to increase WB detection sensitivity by employing different enzyme and/or substrate systems.

Th.A.P.119 SEROCONVERSION: ANTIBODY PROFILES TO HTLV I

Lee, Helen*; Mann, A.**; Gibbs, J.**; Perol, M⁺; Tegtmeier, G.***, Ferchal, F.⁺ and Blattner, W.** *Abbott Laboratories North Chicago, IL. **NIH, Bethesda, MD, USA ⁺ Hopital St. Louis, Paris, France ***Community Blood Center of Greater Kansas City, KC, USA

OBJECTIVE. To determine the antibody profile to the various HTLV I proteins during seroconversion.
METHODS. Serial samples from humans and chimps infected with HTLV I were screened by EIA using purified HTLV I lysate and one using recombinant p40X protein. To study the sequence of the Ig class response, affinity purified anti-human IgG or IgM conjugates were used. The samples were also tested by Western blot (WB) and RIPA.
RESULTS. The anti-HTLV I IgM peak appeared first, 2-3 months after inoculation followed by IgG 1-2 months later. Antibodies to p40X appeared later at a lower level than the anti-HTLV I. Antibody profiles to core proteins (p19 and p24) or to envelope proteins (gp46 in WB and gp61 in RIPA) were varied. In 3 cases, anti-core (anti-p24 in 2 cases, anti-p19 and p24 in one case) was detected prior to anti-gp61. Preferential detection of IgG over IgM by the RIPA procedure may explain the apparent delay of anti-gp61 response. One patient developed antibodies only to p19 and gp61 with no anti-p24. This raises the question of the current guideline of confirmation which only uses anti-p24 as the anti-core marker.
CONCLUSION. The profile of anti-HTLV I reactivity follows a classical course: IgM response followed by IgG. In some cases, IgM antibodies persist, suggesting viral replication. Antibody to p40X is not an early marker in seroconversion. Anti-p19 should be considered as a supplemental marker to anti-p24.

Th.A.P.116 ARE SERONEGATIVE HIGH RISK SUBJECTS HIV-INFECTED ?

Lefrère, Jean-Jacques*; Vittecoq, D.**; Noël, B.***; Chamaret, S.****; Mariotti, M.*; Lambin, P.*; Courouce, A.M.*; Bach, J.F.**; Montagnier, L.****.
*INTS; **Hôpital Necker; ***CTS Chambéry; ****Institut Pasteur, Paris, France.

Objective. To investigate the possible latent infection of subjects exposed to HIV.
Methods. 42 subjects were studied: 17 HIV1 seronegative high risk subjects (11 homosexual men, 6 women) having had numerous unprotected sexual contacts during at least one year with seropositive subjects; 25 seronegative haemophiliac subjects polytransfused before the systematic screening of seropositive blood donations were studied at 2 controls at 6 month interval. Each control included: physical examination (lymph nodes); full blood count; total HIV1 antibodies by two Elisa assays (with confirmation by western-blot if at least one positive Elisa); p24 antigen by enzyme immunoassay; biological markers often abnormal in HIV infection (CD4 and CD8 lymphocytes, serum IgG and IgA levels, serum beta-2-microglobulin and neopterin levels); anti-nef antibodies by western-blot; Polymerase Chain Reaction (PCR): localisation on genome and nucleotide sequence of the primers and probes used were:
- GAG : primer I 1088-1115, primer II 1175-1202, probe 1132-1172
- POL 1 : primer I 2391-2416, primer II 2672-2698, probe 2539-2575
- POL 2 : primer I 4118-4135, primer II 4242-4259, probe 4167-4205

(200 symptomless seropositive HIV1 subjects and 100 healthy seronegative blood donors were respectively positive and negative controls for PCR assay using these primers).
Results. No clinical and biological anomaly was observed in the 42 subjects of the study; PCR (validated by the results of the controls) was negative in these 42 subjects.
Conclusion. This study indicates that latent HIV1 infection in seronegative high risk subjects is not a frequent event.

Th.A.P.118 A RAPID AND SENSITIVE HTLV-I ANTIBODY SCREENING METHOD WITH HIGH SPECIFICITY.

Drummond, J. E.[1], Warner, G. L.[1], Waters, D. J.[1], Blattner, W. A.[2], Breman, G. B.[3], and Thorn, R. M.[3]
[1]Program Resources, Inc., NCI-Frederick Cancer Research Facility, Frederick, MD, USA; [2]Division of Cancer Etiology, National Cancer Institute, Bethesda, MD, USA; [3]Cambridge BioScience, Worcester, MA, USA.

Objective. To develop a rapid and efficient method of screening serum or plasma that is both sensitive and specific.
Method. We assayed 1698 serum samples from various populations including Haitians, mother and infant pairs, IV drug abusers, tropical spastic paraparesis, other diseases, and normal controls for antibody to HTLV-I using the DuPont (DUP) whole virus ELISA and the Cambridge BioScience (CB) recombinant HTLV-I envelope ELISA, which contains a polypeptide with the amino acids 307-313 and 331-420, using the numbering system described by Seiki et al. (PNAS 80:3618(1983)). Samples positive by either assay were tested on the DUP HTLV-I western blot (WB).
Results. There were 65 WB+ samples (p19, p24, and one other viral band), 87 WB- (no bands) and 20 indeterminate WB band patterns. We calculate a specificity and sensitivity of 99.2% and 98.5% for the CB ELISA and 95.1% and 77% for the DUP ELISA. When the results were combined from the two ELISAs, the sensitivity and specificity was 100% and 94%.
Conclusion. The results indicate that the two ELISAs detect different subpopulations of HTLV-I WB+ sera. Their combined sensitivity and specificity allow one to detect all HTLV-I WB+ sera in a rapid ELISA format while minimizing the WB confirmatory testing currently necessary in blood screening studies.

Th.A.P.120 EPIDEMIOLOGY OF AIDS IN THE BAHAMAS

M. Perry Gomez, M.D., K Ofuso-Barko, M.D., R. Bain, R.N.
Princess Margaret Hospital, Ministry of Health, Nassau, Bahamas.

Objective. To describe the Epidemiology of Aids in the Commonwealth of the Bahamas.
Method. Data was obtained from the records of the Aids Outpatient Clinic, Infectious Disease Ward and the Blood Bank of the Princess Margaret Hospital over the period August, 1985 (when Aids testing, Abbot Elisa) was introduced, through December, 1988.
Results.

Year	Cases	M-F:Ratio	Nationality Beh:	Haitians	Cocaine Use	Deaths	Sero Positive
85	36	1.7:1	11	25	6-16%	16	20
86	50	2.1:1	19	31	13-26%	23	85
87	90	1.4:1	46	44	37-41%	44	255
88	93	1.6:1	53	40	36-38%	45	419
Cumulative	269	1.8:1	129	140	92-34%	138	779

Conclusion. Aids is mainly a heterosexual disease in the Bahamas. Contributing factors are Non-IV Use of Free Base Cocaine (crack), Haitian Immigration, and Promiscuity. The role of Free Base Cocaine in the Natural History of HIV Disease needs to be further studied.

A.501 HIV-SEROPREVALENCE AMONG PATIENTS OF A WEST-GERMAN INNER-CITY GENERAL PRACTICE

Zeschel, A.*, Meyer-Glauner, W.**
*Arzt f.Allgemeinmed., **Arzt f.Laboratoriumsmed., Hannover, FRG

Objectives: 1.) To screen selected subpopulations among patients of a general practice as an economical alternative to untargeted mass-screening. 2.) Early detection of HIV-infection among high- and low-risK groups. 3.)To counsel and treat these otherwise unrecognized HIV-carriers as a contribution to the containment of the epidemic. Methods: 175 patients (p) were studied by HIV-AG, -AB and WB-Assay during 2/87 and 10/88. 130 p presented with symptoms comparable to those of the acute retroviral syndrome.27 p were risk group members and 13 were without known risk.
Results:9/175(5.1%)of all tested subjects were AB+. 0 AG+. 4/9 (44.5%) were IVDA. 3/9(33.3%) were heterosexuals without contact to classical high risk groups. 2/9 (22.2%) were homo- or bisex. men. 5/9 (55.6%)were newly diagnosed including all heterosexuals of whom 1 man was infected by a female prostitute.IVDA were diagnosed in later stages of the disease than the others. The male/female ratio among infected p was 2.2:1.In 1988.there was a 2.2-fold number of infected p compared to 1987. All social contact cases of infected p were AB-.
Conclusions:Primary care physicians can detect.counsel and treat a lot of unrecognized AB+ p by screening selected groups of p. There is evidence for heterosex. HIV-spread among the general population.Prostitution is expected to be an important factor in this process.

A.502 HIV INFECTION RELATED TO THE USE OF CONTAMINATED MATERIAL IN COMMERCIAL PLASMA DONORS

B.Clotet,J.Carles,C.Tural,G.Sirera,M.Dominguez,J.Tor,M.Foz.
Infectious Diseases Unit.Hospital de Badalona "Germans Trias i Pujol",Badalona,Barcelona,Catalonia,Spain.

Objective:To identify the risk factors for AIDS reported by 33 HIV seropositive paid blood/plasma donors.
Material:Patients who donated blood in private centers in a retributed manner and were found HIV seropositive.In all cases HIV antibodies were evaluated by ELISA and Western Blot methods.
Results:In 11 out of 33 (33%) there was a history of parenteral drug abuse and in 8 out of 33 (24%) of homosexuality.In the rest,14 patients (43%),six reported sporadic prostitute contacts and the others 8 patients (24%) denied any known risk factors for AIDS.
Discussion:All these 8 patients have donated blood or derivates in private centers,including blood banks in Valencia,Spain, prior to the obligatory law of performing HIV antibodies test in any kind of blood/plasma donation in our country.The accidental recovery of HIV infected blood cells from other donor through the use of the same device system could explain the infection by HIV and the absence of other known risk factors.At least 3 patients have observed that they shared with others the same device for intravenous manipulation. When there is no explanation for the presence of HIV antibodies, people caring for patients at risk for AIDS should be aware of this possibility when questioning risk factors.Our findings agree with those reported recently by Navarro et al (Lancet 1988;ii:42).

A.503 RISK OF HIV TRANSMISSION TO HEALTH CARE WORKERS AND COMPARISON WITH VIRAL HEPATITIDES

Rastrelli, Mario; Ferrazzi, D; Vigo, B; Giannelli, F.
Niguarda Cà Granda Hospital, Milan, Italy.

Objective. To assess the risk of nosocomial transmission of HIV in comparison with viral hepatitides and record the effects of adopting further protective and educational means.
Methods. During the period June 1986-December 1988, all health care workers accidentally exposed to HIV in hospital had entered the study and been evaluated clinically and serologically for evidence of infection at time 0,45,90,180,360 days after exposure. All subjects exposed to viral hepatitides who were not vaccinated against HB and refused serum treatment were submitted to follow up.
Results. 102 subjects had an accidental exposure (needlestick injuries 80; cuts with sharp instruments 12; splashes on mucous membranes 7; splashes on cutaneous wound 3). They represented all occupational categories (nurses 72, physicians 21, midwives 4, others 5). None of them was HIV-positive at basal assay. No seroconversion at ELISA was observed at the follow up (80 patients yet controlled at 6 months). An important decrease of the rate of new accidents occurred after adoption of more protective means since June 1988 (e.g. "hands off" needles, new masks and glasses) and up to date revision of nursing guidelines: 13 cases versus 24,26,30, in the preceding half - year periods. 21 not vaccinated subjects suffered accidents with viral hepatitides contaminated materials and refused to be treated with specific Ig: 6 developed the disease (4 type B, 2 NANB hepatitides).
Conclusions. An important group of health care workers exposed to HIV has not shown evidence of infection whereas the risk of accidental transmission of viral hepatitides is far higher. Even if usual infection control guidelines in assisting HIV infected patients are sufficient to avoid viral transmission, the largest part of exposures (needlestick injuries and splashes) can be prevented using adequate nursing precautions and protective means.

A.504 MONITORIZING PREVALENCE OF HIV INFECTION AND EPIDEMIOLOGICAL PATTERNS THROUGH LABORATORY DATA

Casabona, Jordi.*; Bosch, A.*, Tor, J.**, Segura,A.*
* AIDS Program. Generalitat de Catalunya. Barcelona;
** Hospital "Germans Trias i Pujol". Badalona, Spain.

Objectives: 1.- To estimate the prevalence of HIV infection among people who request, the test in Catalonia. 2.- To describe the demographic and behavioral characteristics of this population.
Methods: All laboratories performing HIV test within the Public Health System are used. The total number of test and their results are collected in a monthly bases. To monitorize trends four periods of 15 days have been defined within a year. A standarized questionnaire on sociodemographic and behavioral data is used by the phisicians to collect information from all patients in which a HIV test has been performed in one the defined period.
Results: 652 (20.1%) out of 3245 performed tests from 17 hospitals during one month period were ELISA positive. Preliminary data from one of the participant centers show the following transmission category distribution of infected patients: 64.5% were intravenous drug users, 21% homosexual/bisexual men, 11.3% reported heterosexual contact as the only possible risk factor and 3.2% were children from parents at risk.
Conclusions: Although demands for HIV test are influenced by multiple varibles and they do not allow for extrapolation of prevalence figures, systematic and homogeneous collection of these data can be an important tool in evaluating the use of laboratory facilities and in the planification of health resources. In conjunction with surveillance of other sentinel populations, it can also result in a better understanding of the distribution and trends of HIV infection in a given population.

A.505 PREVALENCE OF INFECTION WITH HUMAN IMMUNODEFICIENCY VIRUS AMONG DRUG USERS IN PUERTO RICO

Gorbea, Hector F.* and Garcia, M.E.**
*University of Puerto Rico School of Medicine, San Juan, Puerto Rico, U.S.A., **Veterans Administration Medical Center, San Juan, Puerto Rico, U.S.A.

Objective. To study the prevalence of HIV infection among drug users (DU) in a drug treatment program in Puerto Rico (PR).
Methods. DU voluntarily agreed to participate in the study. Information concerning drug use, sexual and medical history was obtained. A screening test (EIA) and supplemental test (Western blot or IFA) were used to determine HIV antibody status.
Results. In 1987 and 1988 a total of 125 ambulatory and asymptomatic DU were tested. Mean age was 36 year-old (range: 24-64) and the mean duration of drug use was 11 years. There were 108 intravenous drug users (IVDU) and 17 non-intravenous drug users (NIVDU). Results are as follows:

Subjects	Number	Seronegative	Seropositive
DU	125	79 (63%)	46 (37%)
IVDU	108	64 (59%)	44 (41%)
NIVDU	17	15 (88%)	2 (12%)

Of the 105 heterosexual IVDU 42 (40%) were seropositive. Drug used by IVDU was reported as follows: heroin and cocaine (76%), heroin (22%), and cocaine (12%).
Conclusion. IVDU in PR are among those at greatest risk for HIV infection.Effective programs to reduce risk are urgently needed.

A.506 INTERNATIONAL NETWORKING OF HIV PUBLIC HEALTH SERVICES

Daniell, Fredric D.*; Skelly, R.*; Sanderson, R.*; Novak, D.**; Cunnion, S.**; et al.
*Navy Environmental and Preventive Medicine Unit, Naples, Italy and **Naval Hospital, Bethesda, Maryland, U.S.A.

Objective. To expand public health capabilities against the HIV epidemic, a networking of existing U.S. Navy preventive medicine programs and approaches was initiated during 1988, utilizing an STD model.
Methods. International networking involves utilization of services provided at a medical center caring for HIV-infected persons, which include specialized counseling and education for HIV-infected persons and their families; evaluation of sexual contacts including spouses and public health partner notification; tracing of involved blood products; screening of high risk populations; and determination of reportable diseases. The Environmental and Preventive Medicine Unit provides guidance on comprehensive public health policy and appropriate procedures; education and training; and consultations related to international sexual partners or blood product cases, throughout Europe, Africa and the Middle East.
Results. This network has collaborated with public health professionals in 40 of the 50 United States and 3 territories, 10 countries and the American Red Cross; in support of the World Health Organization's global strategy. Analysis of HIV and AIDS awareness in the evaluated populations has determined both a very high level of knowledge of potential transmission factors, and a need for additional education related to other aspects of the disease. Analysis of trends of potential transmission factors in over 350 HIV-positive individuals has documented a statistically significant increase in the reporting of blood donations and the history of a spouse, in 1988 as compared to 1987.
Conclusion. The use of an STD model and modification of existing public health procedures and approaches have allowed this network to implement a comprehensive international program in less than 12 months. Initial data indicate that education programs are of assistance in obtaining information leading to evaluations of individuals determined to have been at possible risk for transmission.

A.507 MEN MEET WOMEN: DIFFERENTIAL RISK-REDUCING NEEDS AND TACTICS IN ENCOUNTERS BETWEEN PEOPLE DRAWN FROM THE GENERAL POPULATION POOL.

Ronny A. Shtarkshall* and Awerbech T.**.
*The Hebrew University & Hadassah Faculty of Medicine, Jerusalem, Israel, **Harvard University, Cambridge, MA., U.S.A.

Utilizing equations which were developed for probabilities of HIV infection through sexual intercourse, we demonstrate the asymmetry of the probabilistic risks for a man and and a woman engaging in sexual intercourse in a Western society.
Two factors determine this asymmetry: 1.The prevalence of AIDS and HIV seropositivity varies widely between men and women of specific age groups; and, 2. the infectivity of insertive vaginal intercourse is also asymmetric between the sexes, women being at higher risk. The equations for the two extreme possibilities of a monogamous relationship with many events of intercourse and for multiple partners with one contact with every partner are respectively:

$$P_{monogamous} = pr\,(1-(1-i)^{N})$$
$$P_{multipartner} = 1-(1-pr \times i)^{N}$$

P - probability of being infected in the situation described; pr - probability that the partner is infected (the prevalence of HIV in the group from which the partner is selected); i - the probability that one contact with an infected partner will result in infection; N - the number of sexual encounters.

Solving these nonlinear functions for the ratios of P woman/P man give the relative risks of men and women to be infected in both types of encounters. In a situation where both the prevalence for men is higher and their i is lower for vaginal intercours the Pwomen is much higher.
The implications of these findings are profound when formulating the objectives and concepts of educational interventions among sexually active heterosexuals. While condoms are used by men, it is mainly in the interest of women that men should use condoms. Thus it may be essential to introduce altruistic "cooperative" motives into educational interventions to supplement the "egoistic" one of "safe sex." The introduction of "responsible sex" and its implications are considered.

A.508 "GROUPS AT RISK" AND "RISK BEHAVIORS": THE NEED TO UTILIZE BOTH CONCEPTS IN DESCRIBING TARGET POPULATIONS FOR EDUCATIONAL INTERVENTIONS AND DEFINING THEIR OBJECTIVES

Ronny A. Shtarkshall.
The Hebrew University & Hadassah Faculty of Medicine, Jerusalem, Israel.

The central claim of the paper is that the two concepts, "groups at risk" and "risk behaviror" are neither synonymous nor interchangeable, and that in order to describe target groups for educational or other interventions, both terms are needed. "Risk behavior" or its prevalence is only one component of the definition of a "group at risk;" its other component being the prevalence of HIV within that group. A comparison of two hypothetical groups, since the data on the sexual behavior of actual sub-groups are only approximate, will clarify the distinction betweenn the two concepts.

"RISK GROUP"	PREVALENCE OF HIV IN THE GROUP	PREVALENCE OF RISK BEHAV. IN THE GROUP*	CHARACTERIZATION OF THE GROUP
A	high	high	a group at immodiate risk
B	low	high	a group at future risk (vulnarable)
C	high	low**	low risk unless conditions change ***

* "Risk behaviors" in sexual practices are: multiple partners, low use of contraceptives in general and condoms in particular and high experimentation and variation in sexual practices (including insertive intercourse and/or anal intercourse)

** The prevalence may not be of a behavior but of a condition, i.e., a hemophiliac receiving an infected component.

*** A situation may arise in which the group itself is no longer a "group at risk" because of changing conditions, but its characterization will help to discern another group at risk.

Groups A and B approximate homosexuals/bisexuals and adolescents in Israel, respectively, while group C may represent the sub-population of hemophiliacs after the introduction on sterilized factor.
It is argued that from the point of view of public health, health planning, and the design of educational intervantions, both concepts are essential, since educational interventions for a group at future risk should differ from those for a group at immidiate risk not only because of the characteristics of the group but also because of the characteristics of the risk. "Groups at risk" is therefore a useful and necessary term.

A.509 SURVEILLANCE OF HIV-2 INFECTIONS BY ELISA USING HIV-1 AND HIV-2 SPECIFIC SYNTHETIC PEPTIDES

P. Leinikki, J. Hakulinen, M.-L. Kantanen and H. Brummer-Korvenkontio. National Public Health Institute, Helsinki, Finland.

Objective. To screen for HIV-2 cases in Finland and to evaluate a new test employing HIV-1 and HIV-2 specific synthetic peptides as antigens.

Methods. Serum samples sent for routine HIV-testing from healthy individuals and HIV risk groups were tested by an ELISA with either a combination of, or individual HIV-1 or HIV-2 specific synthetic peptides representing the N-terminal regions of GP-41 (COMBI-test, Pharmacia Inc. Uppsala, Sweden).

Results. Of the 5221 sera negative with other tests, 9 were repeately reactive in the COMBI-test indicating a specificity of 99.84. Among the 25 true positive sera 23 gave no or very little activity with HIV-2 compatible with true HIV-1 infections. Two samples, originating from the same individual reacted with the HIV-2 specific peptide. They also showed GP-reactivity in HIV-2 western blots. The patient had worked in endemic areas of Africa before returning to Finland. One falsely reactive sera also showed high activity against HIV-2.

Conclusion. The result indicates that the test has good specificity and is able to reveal HIV-2 positive cases among samples thought to be HIV-1 positives by conventional techniques.

A.510 HTLV$_I$ SEROPREVALENCE IN A GROUP OF HIV$_1$ POSITIVE ITALIAN SUBJECTS (IN MAJORITY INTRAVENOUS DRUG ABUSERS) - PROEMIAL DATA

Lucia Lopalco, F.Ciccomascolo, P.Lanza, A.Berretta, A.Bini*, S.Sabbatani*
Dipartimento di Bilogia genetica - Università di Milano, Milan;
* Divisione di Malattie Infettive - Ospedale Maggiore Bologna, Bologna, Italy.

Aims we detected the presence of specific HTLV$_I$ antibodies in HIV$_1$ positive subjects to evaluate (1) the percentage of double infection (2) if the subjects with double infection presented an evolutive pattern.

Metods the presence of specific HTLV$_I$ antibodies was tested by Elisa method in 240 HIV$_1$ positive subjects (215 were intravenous drug abusers). The HTLV$_I$ seropositive samples were investigated by Western blot assay.

Results The presence of HTLV$_I$ Elisa reactivity was found in 17 of the 240 HIV$_1$ positive sera (7.08%); this reactivity was not confirmed by Western blot in 2 subjects. 6/17 subjects were AIDS.

Conclusions The data confirmed the presence in Italy of HTLV$_I$ specific antibodies in HIV$_1$ positive subjects like suggested in other epidemiological studies. We need a follow up of HTLV$_I$ and HIV$_1$ positive subjects to evaluate a possible higher evolutive pattern towards AIDS.

A.511 INCIDENCE OF HBV MARKERS AND HIV ANTIBODIES IN BLOOD DONNORS IN LUANDA AND DUNDO, PEOPLE'S REPUBLIC OF ANGOLA

Lourenço, Maria Helena*, Cohen, T. **, Octávio, F. **, Santos-Ferreira, M. O. *, Mota-Almeida, M. J ***, Azevedo Pereira, J. M. *
*Lab. Virology, Fac. Pharmacy, Univ. Lisbon, Portugal **Agostinho Neto Univ.Med.School, Luanda, R P Angola; ***Hosp. Sta. Maria, Lisbon, Portugal.

JNICT GRANT 87-679

Objective: To determine the prevalence of HIV 1 and HIV 2 infection and hepatitis B markers among a cohort of blood donners in two regions of Angola.
Methods: The incidence of HBV markers and HIV antibodies was evaluated in 124 blood donners living in Luanda (74) and Dundo (50). Serological tests for detection of HIV antibody, include the specific HIV 1 and HIV 2 ELISA kits, IFA, W.B.. Cross-reactivity between HIV 1 and HIV 2 large glycoprotein were further tested against a synthetic peptide corresponding to the dominant epitope of transmembrane protein. Serological tests for detection of HBV markers were preformed with ELISA kits.
Results: As shown on table.

Distribution of HIV antibody and HBs Ag, HBs Ab, HBe Ag and HBe Ab according to Laboratory

Service	N°	Seropositivity N° (%)					
	Samp.	HIV-1	HIV-2	HBs Ag	HBs Ab	HBe Ag	HBe Ab
Luanda	74	-	1/74(1.4)	14/74(18.9)	28/74(37.8)	7/74(9.5)	9/74(12)
Dundo	50	3/50(6.0)	8/50(16.0)	21/50(42.0)	21/50(42.0)	10/50(20)	13/50(26)
TOTAL	124	3(2.4)	9(7.3)	35(28.2)	49(39.7)	17(13.7)	20(16.1)

Discussion: The incidence of HBs Ag in sera from Luanda and Dundo is high. HIV 1 and HIV 2 infection exists among blood donners. The highest percentage of positive cases was in Dundo, Northeastern region, border of Zaire. The social and economic consequences of these problems have to be considered.

A.512 ANALYSIS OF A SCREENING PROGRAM FOR HIV1 AND HIV2 INFECTION IN WOMEN OF REPRODUCTIVE AGE.

Victorino, Rui*, Teles L.C.**, Ferreira M.O.***, Guerreiro D.**, Lourenço M.H.***
Foundation of "Bom Sucesso"**, Faculty of Medicine of Lisbon*, and Faculty of Pharmacy of Lisbon***
Av. Prof. Egas Moniz - 1600 LISBON - PORTUGAL.

OBJECTIVES: 1 - To study the prevalence of antibodies to HIV1 and HIV2 in a population of women attending a Family Planning Clinic (FPC) and a antenatal clinic (AC) serving a urban population of 30.000 people where about 10% are of African origin. 2 - Devise a protocol of a study which would maintain characteristics of the "anonymous"studies without the usual limitations of a lack of detailed clinical and epidemiological information about the individuals identified as positive for HIV. 3 - Analyse the problem of the false positive rate in a population of HIV low prevalence.

MATERIAL AND METHODS: All women attending the FCP and the AC from January 1987 to December 1988 were interviewed by a nurse and examined by a doctor, who completed a questionaire covering relevant epidemiological and clinical information related to HIV infection. Blood was collected for routine tests in 700 women (around 80% of those attending the clinics during the period)and a sample saved for testing HIV antibodies anonymously (Elisa from I.Pasteur and Western blot in the Elisa positive cases).A second sample was obtained "anonymously" from cases who were positive in the first sample using the fact that women attend the Center regularly and blood is colected at intervals for routine tests and for this study,under code.

RESULTS: Three out the 650 Portuguese women were positive for HIV1(0.46%)and one out of 50 African women were positive for HIV2(2.0%) in the two samples colected at different times.If the criteria for defining women as seropositive did not include tests on a second sample, the number of "seropositives" in this study would be more than the double of the recorded one.

CONCLUSIONS: A representation of both HIV1 and HIV2 in this urban population was found and the importance of testing a second sample as a means of reducing false positive is documented in this study, where a protocol to repeat anonymously the blood tests was implemented, taking advantage of the special conditions in this health Center.

A.513

Stochastic Models Illustrate Vividly the Connection between Behavior and Risks for HIV Infection.

Gonzalez, José J.*; Myrtveit, M.**; Vavik, L.**.
*ASA, Arendal, **Teachers College Stord, Rommetveit, Norway.

Objective. To use use the power of modern Personal Computers to display graphically the connection between behavior and risk for HIV infection.

Methods. A stochastical simulation model takes into account behavior parameters in a hypothetical risk environment. The correlation between behavior patterns and risk for HIV infection is displayed by means of powerful graphics.

Results. We describe the application of our stochastic simulation model to train medical personnel and school teachers in Norway and West Germany.

A.515

:IS SEXUAL PROMISCUITY A RISK FACTOR FOR HHV6 IN EAST AFRICA?

Fox, Emile*; Constantine, N.* and Abbatte, EA.**
*U.S. Naval Medical Research Unit No.3, Cairo, Egypt (A WHO collaborating center for AIDS), **Direction Technique de la Santé, Djibouti, Djibouti

Objective. To investigate if the B-cell lymphotropic virus HHV6 shares the sexual transmission route of HIV in East Africa.
Methods. 200 sera belonging to 4 groups of individuals from the East African city of Djibouti were tested for antibodies against HHV6. Study groups comprised sexually promiscuous individuals at high risk for HIV, but HIV-western blot negative: 50 female prostitutes in Group 1 and 50 males with a sexually transmitted disease in Group 3; Group 2 comprised 50 female controls and Group 4, 50 male controls. All sera were screened at a 1:20 dilution using IFA (Pan Data Systems) incorporating HHV6 infected and uninfected cells as substrate. Sera with positive reactions were titrated further.
Results. Despite the slightly higher percentage of positive sera (%PS) at the screening dilution in the two study groups, these differences were not statistically significant. Moreover, median titers and geometric mean titers of positive sera were very similar in all 4 groups.

	Group 1	Group 2	Group 3	Group 4
%PS:	82	66	74	70
Median titer:	40	40	40	40
Geometric mean titer:	39	37	38	39

Conclusion. Sero-epidemiological data indicate that HHV6 infection was not more prevalent among sexually promiscuous subjects. Thus, HHV6 does not seem to share the sexual transmission route of HIV in East Africa.
Supported by NAVMEDRSCHDEVCOM, Bethesda, MD Work Unit No. 3M463105H29.AA.335.

A.517

ACCIDENTAL EXPOSURES TO HIV-POSITIVE BLOOD AMONG HEALTH-CARE WORKERS IN 2 SWEDISH HOSPITALS.

JÖRBECK, HANS; Marland, M.; Steinkeller, E. Danderyd Hospital, Danderyd, Sweden.

Objectives: To document circumstances, frequency and outcome of accidental exposures to HIV-positive blood and bloody body fluids among health-care workers.
Methods: This prospective study was started in January 1, 1985. It includes health-care workers in 2 Swedish hospitals giving medical care for HIV-infected persons. All reported notifications of damage with exposure to HIV-positive blood or bloody body fluids among more than 2 500 health-care workers have been studied. Blood samples (including an early blood sample) of the exposed workers have been regularly taken and examined (ELISA).
Results: Around 70 accidents have been reported, so far. Different kinds of parenteral exposures were dominating. So far, all anti-HIV antibody tests have been negative.
Discussion and conclusions: Seroconversion after percutaneous HIV-accidents with blood has been estimated to 5 per 1 000 exposures. In our study no seroconversion in around 40 percutaneous and 30 other HIV-accidents have yet been confirmed, which is to be expected. The majority of the percutaneous HIV-accidents were caused by needle-sticks in combination with phlebotomy, blood-culturing and injections. To our judgment, around 1/3 of the accidents might have been prevented.
This study clearly shows that hazardous circumstances, among others, were manipulation with needles (recapping, disposal, "cleaning up" a o), laboratory work (tubes) and surgery (suture needles). To minimize the hazards in the future we have to identify hazardous circumstances, work etc and do something about it (guarded needles, puncture proof boxes, safe work practice)! Further, we have to educate and inform health care workers, as well as others, about the hazards and change their behavior if needed!

A.514

HIV Screening Efforts in a Low-Risk Population

Magruder, Charles D.*, Sanchez, Jose L.**, Huffman, Paulette*, Lewis, Vassel M.*, Quattromani, Frank L.*.
*Womack Army Community Hospital, Ft Bragg, NC; **Walter Reed Army Institute of Research, Washington, DC, USA.

Objective. To determine the prevalence of HIV antibody seropositivity in a low-risk population.
Methods. The U.S. Army requires HIV testing at least biennially for individuals on active duty. Blood donors are also routinely screened for HIV infection. During the past year, inpatients and some outpatients have received an HIV antibody test. These patient categories are listed below.
Results. High-risk patients, which include people with clinical evidence of HIV infection, individuals treated for substance abuse and contact referrals, have the highest HIV antibody prevalence rate. Patients treated at a sexually transmitted disease (STD) clinic had the next highest prevalence. Routine hospital admission and blood donor screening showed rates similar to or lower than that seen in active duty screening.

HIV SCREENING RESULTS

	# Pos/#tested	Prevalence/1000	95% C.I.
High-risk group	34/2370	14.3	(9.8,19.3)
STD Clinic	11/3107	3.5	(1.0,13.5)
Med/Surg Admissions	2/1812	1.1	(0.0,11.1)
OB/GYN Admissions	1/2246	0.4	(0.0,10.4)
Blood Donors	12/15412	0.8	(0.2,10.0)
Active Duty Screening	61/59004	1.0	(0.8,1.3)

Conclusion. Adjunct HIV screening of routine hospital admissions does not appear to be warranted.

A.516

A PROSPECTIVE STUDY OF HIV INFECTION IN FORMER DRUG USERS: A 4-YEAR STUDY OF 114 PATIENTS

Alessandro Gringeri, M.G.Rumi, M.Colombo, A.R.Zanetti, R.Romeo and P.M.Mannucci. University of Milan, Milan, Italy.

Objective: to assess whether or not stopping drugs has any beneficial effect on the course of HIV infection, inactive drug users living in the community of San Patrignano (Italy) were prospectively followed. Methods: these patients voluntarily enrolled into a rehabilitation program based on agricultural, handicraft and industrial activities and were forcibly taken off drugs during residence. Except for married couples, they had no sexual contacts. Results: since 1985, 293 seropositive, western-blot confirmed, asymptomatic patients have been followed at 6-month intervals for 6-48 months (median 12). 179 patients (59%) were lost because they either reached the end-point of rehabilitation (27%) or left the community (32%).114 patients (81 M, 33 F, 16-42 yrs of age, median drug abuse: 6 yrs) are currently being followed. 65 patients (21.9%, 6.4% annual incidence by life-table analysis) deteriorated to stage IV (CDC), 6 developed full-blown AIDS (5.2%, 1.3% annual incidence). The annual deterioration rate for a control group of 41 active drug users who were followed as out patients between 1985 and 1988 was 28.4% (6.4% vs 28.4% P< 0.01). Conclusions: stopping illicit drugs may be beneficial to the outcome of HIV infection.

A.518

RISK FACTORS FOR HIV INFECTION AMONG INDIVIDUALS SEEKING TESTING IN THE DANISH POPULATION

Schmidt, Kirsten*; Zoffmann, H.*; Krasnik, A**; Brøndstrup, E*; Kvinesdal, B.*
*Statens Seruminstitut **University of Copenhagen, Copenhagen, Denmark.

Objective. To characterize individuals seeking HIV antibody test and to estimate the prevalence of anti-HIV among tested. Methods. Selfadministered anonymous questionnaires distributed together with test results to individuals requesting HIV test in all parts of the health care system in two weeks in Nov. 1987 and April 1988. 2169 (55%) completed the questionnaire. Results. Sexratio F:M=1:0.95; 38%; 34%; and 27% was in the agegroups 15-25, 26-35 and 36+ years of age. 20% of women and 30% of men reported more than one risk factor. Distribution based on hirachical classification of risk factors was:

	Men			Women		
	Anti-HIV neg.		pos.	Anti-HIV neg.		pos.
Reported risk factor	N	(%)	N	N	(%)	N
IV drug abuse	78	(7)	4	40	(4)	
Male homosexual behaviour	163	(16)	13	-		
Sex with IV drug abuser	38	(4)		52	(5)	3
Sex with person from Africa,women:sex with bisexual male	88	(9)	1	198	(18)	
≥1 heterosexual partner within the last 12 months prostitution/sex with prostitute	455	(44)	2	445	(41)	2
None of above	208	(20)		352	(32)	1
Total	1030	(100)	20	1087	(100)	6

The overall prevalence of anti-HIV was 1.2%, highest among men with homosexual behaviour: 8%.
Conclusion: Many individuals seeking HIV-testing are heterosexuals and have a very low prevalence of anti-HIV. Being unable to make valid estimations of the prevalence of HIV infection in the general population sequential prevalence studies may give valuable information about trends in infection rates.

A.519

NATIONAL STUDY OF HIV SEROPREVALENCE IN NATIVE AMERICANS

Conway, George A.*, Hooper EY**, Helgerson SD***, Petersen LR,* Leach R**, Johannes P**
*Centers for Disease Control, Atlanta, Georgia; **Indian Health Service, Phoenix, Arizona; ***Indian Health Service, Tucson, Arizona, U.S.A.

Objective. To assess existing levels and future trends of HIV infection among American Indians and Alaska Natives in the United States.
Methods. Following approval from tribal authorities, blinded seroprevalence testing will be conducted on sera obtained for syphilis screening from prenatal patients, patients undergoing initial evaluation for a sexually transmitted disease, and patients entering drug or alcohol treatment programs. The study will be conducted throughout the Indian Health Service (IHS) (user population of approximately 1,144,000 individuals). Approximately 75,000 sera will be tested for HIV antibodies during a one-year study interval starting in 1989. Results will be stratified by reason for sera being obtained and by rural or urban clinical setting. Data will be aggregated by clusters of ≥ 20,000 service population to further protect confidentiality and ensure statistical reliability of results.
Results. The pilot phase will begin in January, 1989. By March, 1989, surveys are expected to be implemented in many of the IHS service areas.
Conclusion. These surveys will provide relatively unbiased estimates of seroprevalence for the clinic subpopulations of IHS service users. It should also serve as a baseline that may be followed through time for the assessment of the progress of the epidemic and preventive activities in this population.

A.521

SEROPREVALENCE OF HIV ANTIBODY IN A CITYWIDE SAMPLE OF EMERGENCY ROOM PATIENTS

Modesitt Steven* ; Jui J.** ; Stevens P.** ; Hulman S.*; Shriver J.*; Fleming D.**. Oregon Health Division, ** Oregon Health Sciences University, Portland, Oregon, USA.

Objectives. To determine prevalence of HIV antibody in a citywide population of patients seeking emergency room (ER) care.
Methods: Seven hospital-based emergency rooms providing 90% of Portland's emergency services collaborated to simultaneously measure HIV seroprevalence in their combined patient population. During two 48-hour periods in the summer of 1988, all bloods drawn from patients for other purposes were tested for HIV antibody after personal identifiers had been removed. Specimens were also screened for hepatitis B surface antigen (HBsAg) and core antibody (HBc). Demographic and risk factor information as obtained by routine ER practice was linked with test results.
Results. Blood from 444 patients was tested. Patients' residences were evenly distributed throughout the metropolitan area. The largest proportion of patients were in the 20 to 30 year age group (24%)year age group (38%) and in the 60 and over group (38%). Twenty-one patients (0.5%) were identified as intravenous drug users. No males were identified as being homosexual. Seven percent of patients had experienced trauma. Invasive procedures were performed on 34% of patients. Only 2 patients (0.45%, 95% CI ±.62%) tested HIV positive. One of these patients was already known to be HIV positive. Three of 444 (0.68%, 95% CI ±.76%) patients were HBsAg positive and 55 of 444 (12%) were HBc positive.
Conclusion. The rate (0.45%) of HIV seropositivity in this city-wide cohort was low and approximated the rate of HBsAg seropositivity (0.68%). In contrast, the prevalence of HBc (12%) indicates a substantial proportion of this population may be at risk for future HIV infection. This method of population sampling may provide a simple way to estimate HIV infection rates in a general population.

A.523

ACCEPTANCE OF HIV-ANTIBODY SCREENING AND PREVALENCE OF ANTIBODIES AGAINST HIV AT A STD CLINIC

Birgit B. Kvinesdal* and Worm, AM.**
*Statens Seruminstitut; **Bispebjerg Hospital, Copenhagen, Denmark.

During periods of three weeks repeated every third month from October 1987 to November 1988, all persons attending a STD clinic in Copenhagen for examination were offered a blood test for HIV-antibodies. The test could be performed anonymously or not. Data concerning sexual orientation, prostitution, drug abuse and sexual contact with high risk groups were collected. During all four periods 1753 persons attended the clinic. HIV-antibody testing was not accepted by 12.6% of heterosexual men, 9.6% of homo-/bisexual men and 9.9% of the women. No major difference in acceptance of HIV-antibody testing during the four periods was seen. Four heterosexual men, 11 homo-/bisexual men and one woman were found HIV-antibody positive.
The data support that a constant number of clients attending a STD clinic refuse even anonymously HIV-antibody testing and underline the necessity for blinded HIV-antibody testing in order to disclose the true prevalence in this group.

A.520

DETECTION OF HIV ANTIBODIES IN DENTAL SCHOOL AT THE UNIVERSIDAD DE BUENOS AIRES

Crespo,D*;Sabelli,C*;Trica,A*;Brizuela,L*;Ramella,M*;Muchinik, Guillermo**,et al.
*Course of Microbiology,Facultad de Odontología,Universidad de Buenos Aires, **IIHEMA,Academia Nacional de Medicina,Buenos Aires,Argentina.

Objective. To determine HIV-infection seroprevalence in dental professionals, as they represent an important group to study HIV-infection occupational risk.
Methods. A total of 617 subjects was included in this study: 400 first-course students at the School of Dentistry, 112 predoctoral students and 105 dental professionals. Serum samples were tested for HIV antibodies by means of ELISA (Abbott recombinant HTLV III ELISA). Samples reacting positive by ELISA were confirmed by Immunofluorescence or Western Blot.
Results. Only 3(0.75%) males out of the 400 first-course students had HIV antibodies. Risk-factors analysis in the seropositive cases showed that 1 subject was homosexual and intravenous drug abuser and 2 were intravenous drug abusers.
Conclusion. Though dental professionals are likely to be repeatedly exposed to HIV-infected persons, we did not find infection in any of the 112 predoctoral students, nor in the 105 dental professionals, assuming a low risk for the studied group.

A.522

SEXUAL MIXING MODELS WITH LIKE-WITH-LIKE PREFERENCE

BLYTHE, Steve* and Castillo-Chavez, Carlos**.
*Strathclyde University, Glasgow, Scotland. **Cornell University, Ithaca, New York, USA.

Objective. To develop an alternative to proportionate mixing in sexually transmitted disease models.
Methods. Starting from the three fundamental constraints on a mixing function (it must be positive, normalized, and conserve the number of partnerships), a new mixing model can be constructed by finding an appropriate transformation of a suitable function (describing mixing between individuals of similar activity).
Results. A new mixing model is derived, based on a transformation of a local mixing function ("like-with-like") which has the property $f(x-y) = f(y-x)$. Different choices of f provide different degrees of localized mixing in the population, and affect the dynamics of an STD epidemic. We look at three alternatives: Gaussian, rectangular, and "sharp" f superimposed on the general mixing.
Conclusion. Predictions of epidemics of STDs are very sensitive to the extent of like-with-like mixing in the population.

A.524

THE INFLUENCE OF CHANGES IN SEXUAL BEHAVIOUR ON THE TRANSMISSION DYNAMICS OF HIV-1 IN THE UK

Gupta, Sunetra; Blythe, S*; Anderson, R.M.
Imperial College, London, UK; *Strathclyde University, Glasgow, Scotland.

Objective: To assess the consequences of changes in sexual behaviour on the transmission dynamics of HIV-1 with reference to the male homosexual community in the United Kingdom.
Methods: The distribution of sexual activity (rate of acquiring new partners) and transmission probabilities (mirroring the adoption of "safer sex") are altered in a simple model of the transmission dynamics of HIV-1. The model incorporates distributed infectious and incubation periods.
Results: The future course of the HIV-1 epidemic is highly sensitive to the timing and the magnitude of changes in sexual behaviour. The effects of changes in sexual behaviour are not linearly proportional to either the magnitude of the change or the time of its initiation.
Conclusions: The timing of a change in sexual behaviour is crucial in reducing the numbers of future AIDS cases. Great benefit is obtained by changing sexual behaviour as soon as possible, and any delays drastically reduce the impact of a change.

A.525

HIV SEROPOSITIVITY IN IVDU VIETNAM COMBAT VETERANS

Kocurek, Kathryn*, Bacchetti, P.*, Gorter, R.*, Meakin, R.*, Moss, A.R.*. *University of California, San Francisco, California, USA.

OBJECTIVE: To determine the rate of HIV infection in heterosexual military veterans who use intravenous drugs and are seen in methadone treatment facilities.
METHODS: Heterosexual IVDUs attending methadone treatment facilities in San Francisco between February and December 1988 were recruited, screened for military service, and tested for HIV seropositivity. 129 veterans were studied including 34 who were Vietnam combat veterans. 27 subjects were recruited from a Veterans Administration (VA) hospital treatment facility and the remaining 102 from non-VA drug treatment programs.
RESULTS: 0/27 (0%) of veterans screened at a VA drug treatment facility were HIV+ compared with 7/102 (7%) of veterans treated at non-VA programs. 4/34 (12%) Vietnam combat veterans were HIV seropositive, compared with 3/96 (3%) for all other veterans (p=.078). Of the seropositive veterans, four were black, two were Native American, and one was white. Vietnam combat veterans recruited from non-VA facilities had an HIV seropositivity rate of 15% (4/27). For comparison, non-veteran heterosexual IVDUs screened over the same time period had a seropositivity rate of 9%.
CONCLUSIONS: There is a discrepancy in HIV seroprevalence between veterans screened at VA and non-VA drug treatment facilities. The highest prevalence of HIV seropositivity was seen in IVDU Vietnam combat veterans who were not being treated at VA facilities. Larger studies are indicated to assess the significance of HIV infection in this unique population.

A.526

COMPLETENESS AND ACCURACY OF RISK FACTOR INFORMATION IN A GENERAL POPULATION SURVEILLANCE OF HIV INFECTION

Perucci, Carlo A.; Arca', M.; Carboni, A.; Orchi, N.; Spadea T.; Regional Epidemiology Unit, Rome, Italy.

Objective. To detect and quantify the biases due to missing information about risk factor in data from a general population surveillance of HIV.
Methods. Anonymous notification of every confirmed anti-HIV positivity, including available information on risk factor, has been collected by the Latium R.E.U. from local laboratories since October 1985. Multiple notifications referring to the same subject are linked using the available individual data as keys. Further steps are the linkages with clinical follow-up records and notifications of AIDS cases. Every step makes the information about risk factor more complete.
Results.

CUMULATIVE IMPROVEMENTS IN COMPLETENESS OF INFORMATION BY YEAR OF DIAGNOSIS

STEPS YEAR	INFORMATION AVAILABLE %				
	1985	1986	1987	1988	TOTAL
A = FIRST NOTIFICATION	44.5	47.4	64.5	68.5	57.4
B = A + FOLLOWING NOTIFICATION	57.1	56.2	69.8	70.4	64.6
C = B + FOLLOW UP & AIDS CASES	58.8	58.9	72.3	73.6	67.1

RISK FACTOR DISTRIBUTION (%) BY SOURCE OF INFORMATION

SOURCE		MALES				FEMALES		
		IVDA	HOMO	HETERO	BLOOD	IVDA	HETERO	BLOOD
FIRST NOTIFICATION	n=1842	84.7	12.3	1.7	1.3	84.5	14.0	1.4
FOLLOWING NOTIFICATIONS	n= 357	87.8	9.4	2.8	0.0	85.4	13.6	1.0
FOLLOW-UP & AIDS CASES	n= 122	50.0	40.6	6.3	3.1	65.4	34.6	0.0

Conclusions. Willingness of reporting risk factors and validity of surveillance system in assessing them are likely to vary among risk categories. This may result in biased risk factor distributions when based on available information. Use of different sources improves completeness of surveillance data and suggests a way for reducing biases. Data presented must be analyzed by time of testing to take into account changes over time in size and direction of the considered biases.

A.527

TEMPORAL TRENDS OF HIV PREVALENCE IN BLOOD DONORS AND USE OF BLOOD BANKS AS TESTING SITES IN LATIUM (ITALY).

Perucci Carlo A.; Arca' M.; Abeni D.; Chierchini P; Regional Epidemiologic Unit, Rome, Italy.

Objective. To evaluate changes over time in number and characteristics of blood donors and their effect on observed prevalence trends of HIV infection and to evaluate the effectiveness of screening programmes.
Methods. In the Latium region (about 5,000,000 inhab.) screening of every donated blood unit has been mandatory since October 1985. Diagnostic activity for non-donors is still offered by a number of blood banks. Data on number of screened units and positive test results, in occasional and periodic donors, are monthly reported by blood banks to R.E.U. together with anonymous notifications of every positive test results.
Results.

SCREENED DONATIONS AND PREVALENCE OF HIV INFECTION BY YEAR AND DONOR CLASS

YEAR	PERIODIC		OCCASIONAL		TOTAL	
	SCREENED UNITS	P (x10,000)	SCREENED UNITS	P (x10,000)	S.U.	P
1985 (inc.)	4,832	-	10,036	-	14,868	-
1986	30,986	2.9	55,776	2.7	86,762	2.8
1987	43,124	2.6	99,274	4.3	142,398	3.8
1988	56,531	1.4	77,133	5.3	133,664	3.7

NOTIFICATIONS OF HIV POSITIVITY BY YEAR AND TYPE OF REPORTING STRUCTURE

YEAR	LABORATORIES		BLOOD BANKS-DONORS		BLOOD BANKS-NON DONORS	
1985 (inc.)	547	74.7%	126	17.2%	59	8.1%
1986	1578	77.4%	275	13.5%	185	9.1%
1987	2364	85.8%	54	2.0%	337	12.2%
1988 (inc.)	1865	87.8%	31	1.5%	227	10.7%

Conclusions. Number of donated blood units has not significantly decreased; donations from periodic donors increased, while those from occasional ones decreased in 1988. A strong opposite trend is evident for prevalence in the compared donor classes. Even though the proportion of HIV+ reported by blood banks among donors has dramatically decreased, data suggest a still high use of blood donation as a way of obtaining an HIV test. More information on self deferral, and an increased availability of alternative testing sites are needed to ensure safety of blood transfusions.

A.528

HIV SEROPREVALENCE IN HISPANIC AMNESTY APPLICANTS AT A SEXUALLY TRANSMITTED DISEASES (STD) CLINIC, LOS ANGELES, CALIFORNIA, 1988

Nahlen, Bernard*, Keradt, P.**, Ford, W.**, Johnson, M.**, Waterman, S.**
*Centers for Disease Control, GA. USA;**Los Angeles County (LAC) Department of Health Services, CA, USA.

Objective. To estimate and compare HIV antibody (Ab) seroprevalence in undocumented Hispanics seeking legal amnesty with that of other Hispanics attending the same STD clinic.
Methods. Amnesty applicants must prove residence in the USA since Jan. 1, 1982, and undergo HIVAb testing. Repeat ELISA positives are confirmed by immunofluorescent antibody (IFA). Medical charts of all 324 Hispanic amnesty applicants seen at one county STD clinic between Feb. 1-Aug. 31 were reviewed for HIVAb status, demographic characteristics, risk factors, and history of other STDs. HIVAb prevalence in a consecutive sample of 555 non-amnesty Hispanics undergoing confidential or blinded testing in the same clinic was also determined.
Results. *Amnesty:* Males were more likely than females to refuse testing; 87 (51%) of 171 males and 37 (67%) of 55 females accepted. Fifteen percent (18/124) of all tests were HIVAb positive. No females were seropositive. The seropositivity rate for males was 21% (18/87): 61% (11/18) were homosexual and 39% (7/18) were bisexual; none had a history of intravenous drug use or blood transfusion. *Non-amnesty:* 7% (13/186) of Hispanics who accepted confidential testing were HIVAb positive; 5% (20/369) of sera submitted for blinded testing were HIVAb positive. Amnesty applicants were more likely to be HIVAb positive than other Hispanics in this population (p=0.001; Relative Risk 2.44, 95% CI 1.42, 4.19).
Conclusion. Prevalence of HIVAb and risk factors for infection in undocumented Hispanic immigrants to the USA is poorly understood. The seropositivity rate for both groups of Hispanics attending this STD clinic is unexpectedly high. Although no seropositive females were identified in the amnesty group, the high proportion of bisexual seropositive males indicates the potential for heterosexual transmission. Legalization of amnesty applicants provides an opportunity to target more effective education and intervention strategies to this high-risk group.

A.529

SEROPREVALENCE OF HIV ANTIBODY IN IV DRUG USERS AND OTHER PATIENTS IN A CONNECTICUT HOSPITAL

Lyons, Robert W.; Krisiunas, E; Madden, G; Rubinstien, E; Smith, C. and Dauphinais, R. St.Francis Hospital and Medical Center, Hartford, Connecticut, USA.

Objective. To examine the demographics of HIV antibody seroprevalance at a 592 bed community teaching hospital in the northeastern United States in 1988.
Methods. Sex, race, age, and risk-group information was obtained by the laboratory from the ordering physician on all HIV antibody tests done. Patient identifiers were removed before analysis by the epidemiology section. A positive result was positive by both ELISA and Western Blot (RIBA).
Results. 632 adults and 58 infants were tested with their permission. 131 were positive. An analysis of intravenous drug users (IVDU) by race and sex is shown here; similar analysis of the other groups will be given in the presentation:

Group	Total	Pos	%	Group	Total	Pos	%
IVDU	299	85	28.4	Gay	36	13	36.1
Blk Male	102	32	31.4	Gay/IVDU	6	4	66.7
Blk Female	49	13	26.5	Heterosexual	120	9	7.5
Hisp Male	72	26	36.1	Blood Recipient	19	2	10.5
Hisp Female	27	9	33.3	Adult - No Risk	152	10	6.6
Wht Male	27	1	3.7	Child of IVDU	41	8	19.5
Wht Female	22	4	18.2	Child - No Risk	17	0	0.0

Conclusion. The majority of the HIV+ patients tested are Black and Hispanic IVDU. Prevalence rate among white IVDU is significantly less than among IVDU from minority groups.

A.530

THE EPIDEMIOLOGY OF AIDS IN MARYLAND, 1981 - 1987

Horman, Joseph* and Hemidi, Cyrus*
AIDS Administration, MD Department of Health, Baltimore, MD, USA

Objective: Describe the epidemiology of AIDS in Maryland for the years 1981 through 1987.
Methods: Case reports completed as part of the Maryland AIDS Reporting System were analysed.
Results: A total of 1,017 nonincarcerated adult AIDS cases was reported during this 7 year period. The greatest proportion of cases occurred in Baltimore City and Prince George's and Montgomery counties (79% of total), Maryland's largest metropolitan areas. These same jurisdictions had the highest cumulative incidence rates for both blacks and whites. Overall, 50.5% of the cases were black. Statewide, the cumulative incidence rate for blacks is 3.6 times that for whites. Many rural counties had relatively high cumulative incidence rate among black residents (up to 1,266 cases per million). Homosexual/bisexual male was the transmission category most responsible for AIDS. Blood transfusion cases represented 6.3% of the total (compared to 2% nationally). IVDA was a greater factor in the black population than in the white (28% vs. 4%). Temporal trends indicate that IVDA, heterosexual contact (particularly for females) and blood transfusion assumed more importance as a risk factor in Maryland during the years 1985-1987 as compared to 1981-1984. During this period, 23 cases of pediatric AIDS were reported. Eight were female and 15 male. Seventeen were black, 5 white, and 1 hispanic.
Conclusion: The demographic breakdown of Maryland cases was similar to national data for the years 1981-1987. Two major exceptions were a disproportionate number of black cases and cases due to blood transfusions.

A.531

SUIVI PENDANT 3 ANS DES LYMPHOCYTES T4 ET DE LA ß2 MICROGLOBULINE SUR UNE COHORTE DE 166 SUJETS INFECTES PAR LE VIH

BRUGNETTI,Anne ; NEGRE,M ; PESCE,A ; FUZIBET,J.G. ; QUARANTA,J.F. ; DUJARDIN,P ; CASSUTO,J.P. .
C.H.R.U. de Nice, FRANCE. Ligue Régionale Française de lutte contre le SIDA

166 séropositifs groupes II, III, IV ont été suivis pendant 3 ans au plan clinique et biologique avec fréquence trimestrielle.
Objetif : apprécier les modifications de 2 paramètres : la lymphocytose T4 et la ß2 microglobuline sérique, en fonction du temps écoulé et de la survie, afin de voir quel est leur potentiel pronostique indépendamment d'une éventuelle thérapeutique.
Lymphocytes T4, groupe II : 107 cas, taux initial moyen 694 ± 300, à 1 an sur 47 cas : 604 ± 283, à 2 ans sur 33 cas : 523 ± 294, à 3 ans sur 12 cas : 465 ± 249. Groupe III : 47 cas, taux initial moyen 498 ± 291, à 1 an sur 17 cas : 428 ± 267, à 2 ans sur 16 cas : 400 ± 197, à 3 ans sur 10 cas : 302 ± 173. Groupe IV : 12 cas, taux initial moyen 218 ± 233.
ß2 microglobuline : groupe II : 97 cas, taux initial moyen 2,83 ± 1, à 1 an sur 21 cas : 3,14 ± 1,3, à 2 ans sur 7 cas : 4,3 ± 2,4, à 3 ans sur 2 cas : 4,2 ± 1,27. Groupe III : 42 cas, taux initial moyen 3,4 ± 1,4, à 1 an sur 9 cas : 4,1 ± 5,8, à 2 ans sur 9 cas : 3,3 ± 0,72, à 3 ans sur 5 cas : 3,6 ± 0,82. Groupe IV : 12 cas, taux initial moyen 3,9 ± 1,14.
Conclusion : A stade identique, le taux moyen de T4 diminue modérément en fonction du temps alors que le chiffre de ß2 microglobuline augmente discrètement. Il apparaît que ces paramètres ne sont pas suffisamment discriminants pour déterminer l'ancienneté de l'infection ou dégager un pronostic.

A.533

FEDERAL SUPPORT OF STATE AND LOCAL HIV PREVENTION PROGRAMS IN THE UNITED STATES

Bowen, G. Stephen, West, G.R., Kirby, J., Cates, W., Hinman, A.R., Centers for Disease Control (CDC), Atlanta, GA, U.S.A.

Objective: To provide financial and technical assistance to State and local health departments for the prevention of HIV transmission in the U.S.
Methods: CDC is the lead federal agency in the U.S. Government for development, implementation, and evaluation of national efforts to prevent transmission of HIV and to control sexually transmitted diseases (STD). These programs are administered by State and local health departments. CDC has established multi-year cooperative agreements for HIV prevention with all 50 states, Puerto Rico, five large cities, and more than 75 community-based organizations (CBO) in 27 large metropolitan statistical areas. A wide range of mutually reinforcing prevention activities are supported including local/State public information campaigns; studies of knowledge, attitudes, beliefs, and behaviors; counseling, testing, and partner notification; STD treatment; funding of minority and other CBOs to educate and change target community behavior norms; and, outreach and referral of drug users for treatment.
Results: Funds and technical assistance from CDC to health departments and CBOs have greatly increased - from approximately $26 million in 1986 to $143 million in 1989. In 1989, it is estimated that more than 5 million persons will receive risk reduction counseling, 860,000 will elect to be tested, and approximately 43,000 will be seropositive. Since 1987, more than 400 CBOs have been funded.
Conclusion: The foundation for a comprehensive national HIV prevention program in the U.S. has been established. A model for a core HIV prevention program has been defined and partially funded by the federal government.

A.535

AN ANALYSIS OF AIDS IN BRITISH COLUMBIA

Rekart, Michael L. STD Control, Ministry of Health, Vancouver, British Columbia, Canada.
Objective To describe reported cases of AIDS in B.C. through 1988 and to analyze trends.
Methods The 464 AIDS cases reported in B.C. to the end of 1988 are divided into two halves: the initial 232 cases (Group I) and the latest 232 cases (Group II). The characteristics of these two groups are described and compared.
Conclusions Recently reported cases of AIDS in British Columbia are occurring more frequently as a result of heterosexual transmission. All other characteristics have remained stable over time. The incidence of AIDS has slowed considerably.

Results	Group I	Group II	%Total
Male	228	224	97%
Female	4	8	3%
20 y/o	1	1	1%
20-29	45	47	20%
30-39	98	93	41%
40-49	67	68	29%
50+	21	23	10%
Urban	208	202	88%
Rural	24	30	12%
Homosexual - Bisexual	217	208	94%
IVDU	0	2	1%
Homosexual-IVDU	4	5	2%
Hemophilia	1	3	1%
Heterosexual	1(p=.06)	6	1.5%
Blood Tx	6	3	2%
NIR	3	5	2%

Year	New Cases	Cumulative Cases	Rate of Increase
1983	7	7	-
1984	25	32	3.57
1985	56	88	2.24
1986	105	193	1.88
1987	124	317	1.18
1988	154	471	1.24

A.532

SCREENING FOR HIV INFECTION AMONG IV DRUG USERS IN THE PRISONS OF BRUSSELS.

Donot Antoine*, Verhoeven-Lespagnard Liliane*, Lumer Gunter**
* CMC Prison de St Gilles, Brussels;
** Université de l'état, Mons, Belgium.

Objective. To monitor the epidemic of HIV infection among IV drug users (IVDU) in the Brussels area through screening of the inmates of Brussels prisons and, at the same time, monitor the effect of information on the behavior of the IVDU population.
Methods. Since May 1985, an information campaign on AIDS was launched in Belgian prisons. In 42 months, we have tested, having obtained their consent, 3126 newly identified inmates having used IV drugs at least once.
Results. The seropositivity rates were, per semester, 7.1%, 7.1%, 7.7%, 3.2%, 5%, 3.4%, 3.1% respectively.
Conclusions. These results indicate a decrease of the HIV prevalence among the delinquent IVDU of the Brussels area, an urban district of 1,500,000 inhabitants having free access to sterile injection material. We explain the observed decrease by behavioral changes due to the information and screening and we produce a simple mathematical epidemic model consistent with that explanation.

A.534

HTLV-I/II INFECTION IN HIGH-RISK GROUPS IN SPAIN

Genesca, Juan*; Viladomiu, Ll.**; Talavera, JC.**; Shih, J.*; Alter, H.* and Esteban, JI.**. *Department of Transfusion Medicine, NIH, Bethesda, MD, USA; **Hospital Vall d'Hebron, Barcelona, Spain.

Objective. To determine the prevalence of HTLV-I/II infection in Spanish populations at high-risk for HIV infection.
Methods. Serum samples were obtained from 150 subjects (1987-88) distributed in 110 drug users, 15 heterosexual contacts, 22 homosexuals and 3 post-transfusional HIV infections; 93% of them were anti-HIV+ and 10% were symptomatic (ARC/AIDS). Anti-HTLV-I were tested by 3 licensed EIAs (Abbott, Dupont, Cellular Prod.). Repeatedly reactive (RR) samples were confirmed with WB, RIPA and a recombinant p21E (env) WB (Biotech). A + result was defined as the presence of p24 and an env product in any of the 3 tests.
Results. Nine samples (drug users) were RR in at least one of the EIAs:

	PATIENT								
TEST	1	2	3	4	5	6	7	8	9
EIA 1	RR	RR	-	RR	-	RR	-	-	-
EIA 2	+/-	RR	RR	RR	RR	-	RR	RR	RR
EIA 3	-	RR	RR	RR	-	-	RR	-	RR
WB	p24	p19,24	-	p24	p19	-	p19,24	p24	-
RIPA	gp68	gp68	-	gp68	-	-	-	-	-
p21E	+	+	-	+	-	-	+	-	-

Only 4 samples (2.6% drug us.) were interpreted as + (No.1,2,4,7). None of the EIAs was + in all 4 samples. All + samples were detected by the recombinant WB assay.
Conclusion. 1) The prevalence of HTLV-I/II infection in HIV infected groups in Spain is very low; 2) Additional confirmatory testing for HTLV-I/II infection is absolutely necessary; 3) The recombinant p21E WB assay might be an useful confirmatory technique for HTLV-I/II infection.

A.536

EVOLUTION TOWARDS AIDS IN A GROUP OF ITALIAN INTRAVENOUS DRUG ABUSERS(IDA) WITH PGL

Roberto Luzzati,D.Giraldi,M.Malena,R.Mazzi,S.Ciaffoni*,C.Rosta .Institute of Infectious Diseases,Verona *Blood Transfusion Service,Verona,Italy.

Objective.To evaluate the 3-year progression rate to AIDS in a group of IDA with PGL in Verona (Italy).
Methods.One hundred and thirtytwo IDA (mean age 27 ± 6 years) with PGL were enrolled in a prospective study between July 1984 and June 1986.Except for PGL,all patients were symptomless and had CD4+ lymphocytes above 400/ml.The patients were followed up at intervals of 3-6 months for a median period of 36 months (range 30-40 months).None received anti-HIV or immunorestaurative drugs during the period of observation.Progression to full-blown AIDS was established according to CDC revised surveillance definition (1987).Kaplan-Meier analysis was used to estimate the 3-year incidence rates of AIDS.
Results.AIDS was diagnosed in 5 patients.The 1-year incidence rate for AIDS was 1.23% ; the 2-year rate was 1.33% and 3-year rate was 4.64%.Therefore,the rate of progression to AIDS increased over the period of follow-up.The current actuarial progression rate of PGL to AIDS at 3 years results 7.2%.
Conclusion.The beginning of HIV epidemic in large italian cities dates back at least to 1981.Our finding suggests that IDA could present lower progression rates to AIDS than other groups at risk of HIV observed in recent prospective studies.

A.537

IMPACT OF REVISED CASE DEFINITION ON AIDS SURVEILLANCE IN EUROPE

Ancelle-Park, Rosemary*; Couturier, E.*; Brunet J.B.* and national surveillance correspondants of 31 countries
*WHO Collaborating Centre on AIDS, Paris, France.

Objective: To determine the modalities of application and impact of the revised CDC/WHO AIDS case definition on surveillance in Europe.

Methods: A survey was carried out among the 32 countries of the WHO European region investigating modalities of surveillance of AIDS and application of revised cases definition.

Results: Of 20 countries having answered by end of january 1989, 15 have set up a surveillance system for HIV+ individuals. 20 countries have an AIDS surveillance system of which 13 are mandatory and 6 voluntary. Under reporting has been assessed by few countries 9/20 mostly by matching AIDS cases with death certificates. Revised case definition was applied in all 20 countries by 01/01/88. Six countries have actively carried out a retrospective investigation on cases previously reported with AIDS and 3 have also investigated HIV patients not previously diagnosed with AIDS. 636 AIDS patients fitting the revised case definition have been reported representing an increase of 4%. This is much lower than figures reported in literature.

Conclusion: Most of the 20 countries having answered by end of january 1989 had applied the case definition by first of january 1988. Impact of new cases is extremely low and will be assessed when complete set of answers are received.

A.538

THE INCIDENCE OF GLOVE PUNCTURE DURING CAESARIAN SECTION AND VARIOUS POTENTIAL SOLUTIONS.

J R SMITH* & J M GRANT†, Departments of Obstetrics, *St Mary's Hospital, London, and †Bellshill Maternity Hospital, Lanarkshire, United Kingdom.

A study was performed to ascertain the incidence of glove puncture at lower uterine segment Caesarian section. The increasing incidence of Hepatitis B and HIV infection in women makes this of increasing importance to surgeons. The following results were obtained:

Total Caesarian sections	200	
Total where glove(s) punctured	107 (54%)	
Puncture Occurred - During emergency Caesarian section*	64/116 (55%)	
- During elective Caesarian section	39/74 (53%)	χ^2 = 0.0111; 0.10 < p < 0.05
-Uterus eventrated#	51/85 (60%)	
-Uterus not eventrated	50/110 (45%)	χ^2 = 4.063; p < 0.05
-During closure of uterine muscle	34/60 (57%)	

*Not stated whether emergency or elective section in 10 cases. #Not stated whether eventrated or not in 5 cases. This trial shows the highest rate of glove puncture yet reported during a surgical procedure. We are currently undertaking a controlled trial of a new forceps designed to grip both uterine muscle and needle more effectively. The use of double gloving, blunt tipped needles, new gloves thickened at the fingers and the increasing use of staples for skin closure should also reduce this unacceptably high rate of puncture.

A.539

MODIFICATIONS ET VARIATIONS GEOGRAPHIQUES DES GROUPES DE TRANSMISSION DE L'INFECTION A VIH EN FRANCE

Jestin, Christine, Ligue Française pour la Prévention des Maladies Infectieuses, France.

Objectif. Préciser la répartition actuelle des groupes de transmission sur l'ensemble des sujets infectés par le VIH quelque soit le stade, en France.
Méthodes. Recensement de tous les sujets séro-positifs hospitalisés ou vus en consultation dans 20 Services de Maladies Infectieuses du 1er juillet 1987 au 1er juillet 1988.
Résultats. Sur 3873 sujets recensés, dont 80 % non atteints de SIDA, la répartition des groupes de transmission était la suivante : homosexualité ou bisexualité 37 %, toxicomanie iv 43 %, hétérosexuels 7,8%, transfusion et hémophiles 6,8 %, autres et indéterminés 5,1 %. Le pourcentage de toxicomanie iv était le plus élevé dans le Sud, à Marseille, 80 % et à Nice 66,6 %, et le plus faible dans le Nord, à Lille, 12 %.
Conclusion. Le groupe de transmission toxicomanie iv est pour l'ensemble des sujets séropositifs nettement plus important que pour le seul groupe des SIDA déclarés (20 % des SIDA en 1988). Ce groupe est surtout important dans la zone méditérranéenne, comme pour l'Italie et l'Espagne. Il représentera le groupe le plus important des malades atteints de SIDA dans les prochaines années en France.

A.540

HIV SEROPOSITIVE MEN INFECTED WITH MULTIPLE CMV STRAINS: A LONGITUDINAL STUDY OF THE RELATIONSHIP TO T-CELL SUBSETS

Leach, Charles*; Detels, R.**; Visscher, B.**; Giorgi, J.* and Cherry, J.*
UCLA *Sch. of Medicine and **Public Health, Los Angeles, CA, USA.

Objective. To investigate the relationship between serial infection with multiple CMV strains and T-cell subsets.
Methods. We identified 56 asymptomatic HIV-1 seropositive homosexual men participating in a study of HIV-1 infection who excreted CMV from semen at two visits 5 to 9 months apart. CMV DNA was isolated from paired isolates in six men, cut with restriction enzyme and then subjected to junctional hybridization. Lymphocyte subsets were determined by flow cytometry.
Results. Paired isolates from each of 2 men gave identical banding patterns (Group 1). Four men were found to excrete a non-identical strain at the second visit (Group 2). Both groups had lower CD4 and CD8 counts at the second visit (mean decrease in CD4: 27% (Group 1), 35% (Group 2); mean decrease in CD8: 14% (Group 1), 33% (Group 2)).
Conclusion. Serial excretion of multiple CMV strains occurs in asymptomatic HIV infected homosexuals. All 6 subjects persistently shedding CMV had decreases in CD4 and CD8 cell counts. Evaluation of the remaining CMV isolates (in progress) is necessary in order to determine whether men with multiple strains have different changes in T-cell subsets than men with identical strains.

A.541

SAFER SEX BEHAVIOR REINFORCEMENT IN PUBLIC PARKS

Lerro, M., Freeman, A., Valentine, J., Haley, Charles E.
Dallas County Health Department, Dallas, Texas, USA.

Objective: Reinforce safer sex behaviors among sexually active gay men.
Methods. Health department staff learned of the high frequency of contact for sexual purposes among gay and bisexual men, particularly at one public park in a gay-identified neighborhood in Dallas. The health department employees prepared packets for distribution in the park. Each packet contained condom packages coded with a red stripe, safer sex brochures, and a list of services available at the health department, including anonymous HIV antibody testing and counseling. The packets were distributed to park patrons who appeared to be in the park for the purpose of arranging sexual contact. Adult male park patrons were approached individually by health department staff using casual, non-threatening behavior. The park patrons were offered the plain white packets and were told the packets were "free product samples." Anecdotal information was collected about the manner of the patrons, the frequency of entering and leaving the park, the peak hours for patron contact in the park. Demographic information was collected.
Results. Coded condom packages were found in the park after the health department began the packet distribution. Patrons accept the packets, are not threatened, appear interested in the material and appreciate our effort in coming to them. Patrons have called the health department and ordered literature on HIV in individual and in bulk quantities. Conclusion: The low-key approach used by health department staff promotes a sensitive image of the health department as it also facilitates safer sex behavior reinforcement.

A.542

PREVENTION OF PERINATAL TRANSMISSION OF HIV

Berman, Stuart. Centers for Disease Control, Atlanta, GA U.S.A.

Objective: To report progress to date by projects to prevent perinatal HIV transmission.
Methods: Nine demonstration projects evaluate and facilitate the use of contraception and encourage risk reduction among women HIV-infected or at highest risk for infection.
Results: The projects, funded for $4.6 million per yr, are a major way for CDC to develop perinatal HIV prevention interventions for implementation by State programs and provide additional resources targeting minority and highest-risk populations. Projects will address 2 factors determining HIV seroprevalence among newborns: HIV prevalence among women (15-44y) and birth rates among those HIV(+). Efforts have focused on limiting spread and increases in prevalence of HIV among women. However, effective program development requires data about contraceptive practices and attitudes and about reproductive decision-making among women such as female intravenous drug users (IVDUs) and sex partners of drug users--the mothers of 75% of pediatric perinatally-acquired AIDS cases. In 10 cities women who are crack users, IVDUs, sex partners of IVDUs, prostitutes, or HIV+ will be accessed in public clinics, obstetric units, drug treatment, through referral by community organizations, and by outreach; among 4000, efficacy of referral, use of contraception, and risk reduction will be evaluated and facilitated. Among them, pregnancy rates, knowledge, attitudes, and determinants concerning use of contraception will be assessed.
Conclusions: These projects should provide information to direct efforts to prevent perinatal HIV transmission.

A.543

VIH, SYPHILIS ET TOXICOMANIE.

ESPINOZA Pierre*, LOUBEYRE J.L. *, BENAMOUZIG R.*, BOUCHARD I*
* Etablissement d'Hospitalisation Public National de Fresnes, FRANCE.
Allée des Thuyas 94261 FRESNES CEDEX FRANCE.

INTRODUCTION : L'échange de seringue chez les toxicomanes expose au risque de contamination VIH, les taux de séropositivité sont élevés (> 50%) chez les drogués en région parisienne. Les riques de transmission sexuelle sont peu documentés dahs cette population.

OBJECTIFS - METHODES : Préciser et comparer le mode de vie sexuelle, les taux de séropositivité VIH1, les marqueurs de la syphilis chez les toxicomanes IV et les toxicomanes sniffeurs. Conditions : consentement, confidentialité, anonymat.

RESULTATS : Population : toxicomanes de sexe masculin, incarcérés en Juin 87 : 63IV, 18 sniffeurs (jamais d'injection) Pas de différence statistique pour l'âge (27 ans), la fréquence de l'usage de drogue (3/jour) la durée de la toxicomanie (5ans), les caractéristiques de la vie sexuelle : 72 étaient hétérosexuels, 2 homosexuels, 5 bisexuels,pas de rapport 2 cas. 21 avaient des rapports uniquement avec leur concubine et 9 (11%) avec des prostituées. Parmi les partenaires sexuelles féminines 40% utilisaient des drogues IV. Une différence statistiquement significative est retrouvée pour les facteurs suivants :

	VIH +	VDRL et/ou TPHA +	Nouveau partenaire(1an)
IV n = 63	30 (45%)	17 (27%)	4
Sniff n = 18	0	2	1

CONCLUSION : lacontamination VIH1est liée à la toxicomanie IV. La fréquence de la syphilis chez les IV et sniffeurs fait craindre des risques de transmission hétérosexuelle du VIH1

A.544

DETECTION OF OCCLUSION vs LEAK IN CONDOM.RHEOLOGICAL TEST.

Torres,José*;Anabitarte,M.*;Usieto,R.*;
Noguera,E.*;
*Comité Anti-SIDA, Barcelona, Spain.

Objective.The condom is recommended and used as an efficient barrier against HIV and others.In practice,the film of a condom may present irregularities or leaks.This has been resolved efficiently with rigorous sampling plans for leak-detection tests,realized in all standards by conductometric or electronical test(ET).But,as the test is made on a condom in repose and without mecanical tension,eventually existing micro-occlusions or micro-chaps would not be detected as leak.Given that a condom in use in sexual relations is submitted to forces and mecan.deformations,there could appear leaks,invisible in condom without tension,and the protection the is lost.To evaluate this loss of protection vs HIV due to appearance of leaks while using(stretching)condom,it is proposed to test with Rheological test(Pat.Met.) Methods.We tested with usual test ET and Rheological Test 2 homogenuous lots of 2 different manufacturers, considering the presence of leak at the indication of 50mV(ISO 4074,UNE 53625) and 50mV(Rheological Test RQTS 88.E1.PM1.) Results. With standard method ET (condom in repose)there was no leak found.The Rheological Test detected 1 and 14 leaks in the two manufacturers respectively. Conclusion.1) Condoms can present micro-occlusions or micro-chaps which will be transformed into leaks and holes and they will loose their protection effect against HIV when submitting them in use to forces and deformation.

2) The leak detection tests for condoms with the Rheological Test permit to reject non-safe condoms with micro-occlusions or micro-chaps which would not be detected by usual tests(ET).

A.545

EARLY COURSE OF HIV INFECTION IN 40 SEROCONVERTERS

Alessi,E.;Muratori,Simona;Zerboni,R.;Cusini,M.;Carminati,G. and Mansi,M.
1st Clinic of Dermatology,University of Milan,Milan,Italy.

Objective. To study the natural history of HIV infection.

Methods. Forty homosexuals, who became seropositive from December 1985 to January 1988, were followed from 11 to 36 months (mean 23 months). The mean time between the last negative and first positive tests was considered to be the time of infection. Clinical,immunological and virological parameters were assessed at enrolment and every 4 months.

Results. Generalized lymphadenopathy developed in 15 patients from 3 to 15 months,hairy leukoplakia in 4 (after 6,15,17 and 22 months)and constitutional symptoms in 3 (after 11,21 and 29 months). The development of constitutional symptoms was accompanied by HIV antigenemia, but symptoms and antigenemia spontaneously regressed in 2 of 3 patients after few months.No statistically significant modification of immunological parameters was observed in about 50% of patients. Only one patient developed profound immunosuppression.

Conclusion. Our follow up study demonstrated the variability of the course of HIV infection. None of the laboratory parameters analyzed seemed of value in predicting the disease progression.

A.546

NATURAL HISTORY OF HIV INFECTION IN FEMALES SEEN AT THE MEDICAL COLLEGE OF VIRGINIA (MCV).

Barry, Alison, Fortner, C., Settle, J., Kaplowitz, L., Medical College of Virginia, Richmond, VA, U.S.A.

Objective. To describe the natural history of HIV infection in females seen at MCV.

Methods. This study retrospectively compares the clinical course of 66 HIV infected women with 412 HIV infected men followed at MCV from 4/86 to 1/89.

Results. Females comprised 14% of the HIV infected population seen at MCV; 50 (77%) were black, 14 (22%) were white, and 1% was Hispanic. Their major risk factor for acquiring HIV was IV drug use 31 (47%), sexual contact 26 (40%), blood products 8 (12%) and 1% health care exposure. During this time 33% of the women had AIDS compared to 52% of the males. Although a similar proportion of men and women were taking zidovudine the mortality rate for females was only 16% compared to 30% of the male HIV infected population (p <0.05). Ten percent of men and women took zidovudine and T-cell counts were higher in women (p<.05). Of patients still alive survival time (date of HIV diagnosis to present) was longer in men than women (p<.05).

Conclusion. The natural course of HIV infection in women is less well known than in HIV infected men. The lower mortality rate for women in this study may reflect later infection. Further investigation is required concerning the natural history of HIV infection in women.

A.547

PROFIL ÉPIDÉMIOLOGIQUE DES INFECTIONS DUES AU VIRUS D'IMMUNODÉFICIENCE HUMAINE (VIH) EN ESTRIE.

Duperval,Raymond; Boivin,D.;Marcoux,JA.;Lépine,M.;SAAD,WP.;
Université de Sherbrooke, Sherbrooke, Québec, Canada.

Objectif. Décrire la population infectée par le VIH dans un milieu plutôt rural afin d'en souligner les différences par rapport au milieu urbain.

Méthodes. Étude rétrospective de tous les cas de SIDA (S), para-SIDA (P.S.) et infections asymtomatiques (IA) diagnostiquées au CHUS et dans ses hôpitaux affiliés entre octobre 1982 et octobre 1988.

Résultats. 85 personnes infectées ont été diagnostiquées dont 30 S,20 PS et 35 IA. Les facteurs de risques (FR) pour cette population se lisent comme suit: homo-bisexualité 60%, drogues IV 2.3, sang et dérivés 17.6 et contact hétérosexuel 14.1. Le nombre de cas de S est passé de 3 par an en 1986 à 1 par mois en 1988. 40% des S étaient des hétérosexuels (He), dont 20% de femmes. Le contact avec une personne infectée (25%). La promiscuité He (33.3) et la transfusion de sang ou dérivés contaminés (33.3) étaient les FR le plus souvent identifiés chez les He. L'âge moyen des S est de 48.3 pour les femmes et 39.75 ans pour les hommes. 86% des cas de S ont été diagnostiqués en Estrie, mais 37% seulement se sont infectés en Estrie.

Conclusion. L'infection par le VIH est en progression constante en Estrie. Le S atteint la population He de façon plus importante que dans le reste du Canada (40% vs 18%): l'âge médian des personnes He atteintes, est relativement élevée (56a.). La contamination He (23% vs 5.9) et sanguine (13% vs 4.6) est plus élevée que dans le reste du pays. Une proportion importante des S diagnostiqués en Estrie s'est contaminée hors Estrie. Ces particularités régionales de l'infection à VIH devront être prises en considération dans les campagnes d'information et de prévention.

A.548

LONG TERM FOLLOW-UP OF HOMOSEXUAL MEN WITH PERSISTENT LYMPHADENOPATHY: ATTACK RATE FOR AIDS.

Sepkowitz,K.; Gold, J.W.M.; Campbell, S.W.;
Armstrong, D.
Memorial Sloan-Kettering Cancer Center (MSKCC),
New York, N.Y, U.S.A.

Objective. To determine the attack rate for AIDS in a cohort of 93 homosexual men identified with lymphadenopathy between 1981-1983.

Methods. Cases of AIDS occuring in a previously described cohort (Medicine 1985; 64: 203-213.) followed at MSKCC were documented. Patients lost to follow-up (LF) were traced. The attack rate as of 30 Jan., 1989, was calculated (Kaplan-Meier survival curve).

Results. 25/41 LF were traced. 52 patients had been continuously followed. 3 HIV negative patients were excluded. 40 patients developed AIDS, 1 died without AIDS, 30 were alive without AIDS and 19 were LF. The attack rate for AIDS was 58.4% at 7 years.

Conclusion. The average annual attack rate for AIDS has been 8.3%/year in this population.

A.549

LACK OF ASSOCIATION BETWEEN FREQUENCY OF BLOOD DONATION AND SEROPOSITIVITY FOR HIV AND OTHER INFECTIONS; AN UNEXPECTED FINDING IN RIO DE JANEIRO - BRAZIL.

Ramos Filho,C.F.*; Perez, M.A.*; Chain, R.*; Martins, F.S.V.*; Jesus, V.C.* and Martins, C.N.*
* Federal University of Rio de Janeiro, Rio de Janeiro (RJ) Brazil.

Objective: Due to the importance of blood transmission in the difusion of infectious disease in RJ we have performed this study in order to better understand blood transmitted disease and frequency of blood donation.
Methods:2,858 (non-paid) blood donors (18 to 60 years old) from the hemoterapeutic center of our hospital, between january and june 1987 were submitted to VDRL, ELISA-ABOTT (HIV), Complement Fixation (Chagas) and RIA (HBsAg). An extensive questionnaire was submitted by a trained nurse in order to determine possible risk factors. Chi Square test and confidence limits were used for statistical analysis.
Results: The prevalence among blood donors (95% confidence interval) was found to be 4.45% for Lues (3.69-5.21);0.56% for Chagas (0.29-0.83);0.7% for HBsAg (o.39-1.1);0,21% for HIV (0.04-0,38); The overall reaction for at least one of these infections was 5.67% (4.82-6.52). There was no statistical significance ($p<0.05$) between frequency of blood donation and seropositivity for HIV, Chagas and HBsAg.Statistically significant results were found for Lues and blood donation frequency ($X2=7.75$ $p<0.001$). We have also tested for possible association among the positive blood samples, in wich Chagas and HBsAg were statistically significant ($X2=51.46$ $p<0.001$).
Conclusion: Our results show that the association between frequency of blood donation and reaction to most of the disease studied was very poor as it was for sexualy and blood transmited disease. Fidings about Chagas and HBsAg were unexpected.

A.550

SEROEPIDEMIOLOGY OF HUMAN IMMUNODEFICIENCY VIRUS TYPE-I AND VIRAL HEPATITIS INFECTION IN NEW YORK CITY INTRAVENOUS DRUG USERS (IVDUs)

Brown, Lawrence S.*+; Kreek, M.J.**; Trepo, C.***; Chu, A.*; Ajuluchukwu, D.*; Phillips, R.*, et al. *Addiction Research and Treatment Corporation, Brooklyn, +Harlem Hosptial Center, **Rockefellar University, New York, NY, USA; ***Faculte Alexis Carrell, Lyons, France.

Objective. To examine the behaviors associated with HIV-1 and viral hepatitis infection in IVDUs enrolled in drug treatment.
Methods. As a part of a larger HIV seroprevalence study in which a standardized questionnaire was administered, 50 subjects recruited from patients enrolled in drug treatment in NYC in 1987. Sera was collected and analysed for HIV-1 antibodies (using ELISA and Western blot assays) and for hepatitis B virus (HBV) and hepatitis delta virus (HDV) antibodies and antigens.
Results. The HIV-1 infection rate was 54% and 86% of the subjects had at least one marker for HBV infection. Serological evidence of anti-HBc, anti-HBs, anti-HBe, HBsAg, and HBeAg was found in 86%, 70%, 38%, 2%, and 0%, respectively of the sample. No subject had serological evidence of HDV infection and HIV-1 was associated with anti-HBc ($p=.0073$) serostatus.
Conclusions. These findings are consistent with similar mechanisms of transmission between HIV-1 and HBV and suggest that a HBV vaccination program among IVDUs enrolled in drug treatment would have significant public health benefits.

A.551

TRENDS IN AIDS INCIDENCE BASED ON ACTIVE SURVEILLANCE IN 12 MEDICAL SCHOOL AFFILIATED HOSPITALS

Lavenhar Marvin A. and Schneider, D.J.
UMDNJ-New Jersey Medical School, Newark, New Jersey, U.S.A.

Objective. To demonstrate how trends in AIDS incidence can be assessed utilizing data obtained through active surveillance in 12 hospitals affiliated with the New Jersey Medical School.
Methods. Analyses will focus on descriptive methods for presenting data in tabular or graphic form. Survival analysis (with co-factors) will be used for comparing survival following diagnosis among population subgroups.
Results. Some of the major findings to be presented include:

1. Since 1981, 2219 confirmed adult cases of AIDS have been reported, including 75% males, 68% Black, 20% White, and 12% Hispanic.
2. After annual increases from 1981 to 1987, new cases declined in 1988.
3. The primary modes of transmission were: a) IV drug use (66%), b) homosexual/bisexual contact (16%), a and b (5%) and heterosexual contact (8%).
4. AIDS incidence among homosexuals/bisexuals has decreased; heterosexually transmitted AIDS has increased, accounting for 12% of new cases in 1988.
5. Case fatality rates are highest among homosexuals/bisexuals with AIDS.
6. Among homosexuals/bisexuals with AIDS, the incidence of Cryptococcosis and Kaposi's sarcoma is increasing; HIV encephalopathy is increasing among heterosexuals with AIDS.

Conclusion. The application of descriptive methods to local surveillance data can be useful for projecting future treatment needs, targeting population subgroups for intervention, and identifying leads for further investigation.

A.552

COINFECTION VIH1 ET HTLV1

Patey, Olivier*; N'Go, N**; Dublanchet, A.**; Lafaix, C.*
* Service des maladies infectieuses et tropicales, ** Laboratoire de microbiologie, Villeneuve St Georges-France.

Objectif : rechercher la séroprévalence du HTLV1 chez des patients infectés par le VIH.
Méthodes : 170 sérums positifs pour le VIH ont été testés pour le HTLV1 par ELISA. Les sérums appartenaient à différents groupes à risque (toxicomanes, homoxesuels, post-transfusionnel, materno-foetal, et hétérosexuel). Les sérums positifs en ELISA ont été confirmés en Western Blot.
Résultats : 4 sérums ont été positifs en ELISA dont 2 confirmés par Western Blot.

	Sexe	Age (ans)	Origine géographique	Facteur de risque	P19	P24	P28	P53
Patient 1	M	27	France	Toxicomane	+	+	+	+
Patient 2	M	38	Sénégal	Hétérosexuel	+	+	-	-
Patient 3	F	31	Congo	Hétérosexuel	+	+	+	-
Patient 4	F	31	Haïti	Hétérosexuel	+	+	+	+

Un seul patient toxicomane était positif et présentait par ailleurs une cirrhose post-hépatique B. Le conjoint de la patiente 4 est VIH + mais HTLV1 -.
Conclusion : la séroprévalence ELISA HTLV1 apparait faible (2,4%) et survenant essentiellement chez des patients venant de zones de forte prévalence (Afrique, Caraïbes). Ces résultats apparaissent identiques à ceux d'autres études effectuées en région parisienne.

A.553

Human Immunodificiency Infection in the Elderly: A Retrospective Analysis of 20 patients

J. Thompson M.D., R. Kapila M.D., and F. Tecson M.D.
New Jersey Medical School and VA Hospital East Orange N.J. U.S.A.

From January 1985 to June 1988 Twenty (20) patients over the age 60 years were diagnosed with HIV Infection/Aids according to CDC criteria group I-IV. Their ages ranged from 60-85 years with a mean of 66.1. The group included 18 men and 2 women. The risk factors for the men were Homosexuality, 6/18 (33%), IVDA 3/18 (15%), Hetersexual contact 1/18 (6%), both IVDA and sexual contact 2/18 (11%), blood transfusion 2/18 (11%), unknown risk factor 4/18 (22%). The risk factor for both females was heterosexual contact. The initial presentation of AIDS in the men was opportunistic infection. Pneumocystic (PCP) 9/18 (50%), Mycobacterium Tuberculosis(MIB) 3/18 (11%), concomitant PCP and MIB, 1/18 (6%) and fatal bacterical sepsis 2/18 (11%). Two males had malignant lesions; one with Kaposis Sarcoma and the other with Multiple Myeloma. On of the two women had PCP and the other was an asymptomatic carrier. 50% of both males and females presented with oral thrush and 45% had a history of Herpes Zoster. Several significant differences were noted in contrast to younger patients (YP) less than the age of 60. 1. The course of the disease was more aggressive. Only 1 of 10 patients with PCP (100% with Adult Respiratory Distress Syndrome) survived the initial episode. 2. 75% of elderly patients died within 3 months of diagnosis, compared to an average life span of 18-24 months in YP. PCP was often confused with exacerbation of Chronic Lung Disease and Congestive Heart Failure. 4. Cryptococcal meningitis, Cerebral Toxoplasmosis and HIV Encephalitis were often confused with organic brain syndrome, cerebral arterosclerosis and alcohol related brain injury, with initial manifestations of mental deteriation and fatigue. 5. Drug toxicity including Azidothymedine was extremly common, (up to 70% in the elderly HIV population compared to only 30% in YP).
In conclusion elderly patients with HIV usually have a typical predentation, increased severity and prognosis of HIV related illness and greater drug toxicity.

A.554

HIV INFECTION IN JUDICIAL AUTOPSIES

Barbieri, DD*; Buchala, CM**; Guidugli, R*** - Lima, LO*
*Centro de Regerência e Treinamento da Secretaria de Estado da Saude de Sao Paulo; **Faculdade de Saude Publica, Universidade de Sao Paulo; ***Instituto Médico Legal-Sao Paulo Brazil.

The violent deaths, the suspects deaths and deaths with any delictous evidence must be investigated by a judicial autopsy. Considering the stigmatizing character of AIDS, the high incidence in homosexual and drug abusers and the high prevalence in prisons we expected that suicide, homicides and suspect deaths could occur in persons with AIDS more than in the general population. Through a retrospective approach of the reports of the "Instituto Médico Legal" of Sao Paulo City a statistical analisis will be done of the victims seropositives to the HIV as well as a comparison with the behavior of AIDS in Sao Paulo City. It will be also discussed the probable nexus between AIDS and the mechanisms of death. From May 1985 to October 1988, 97 bodies infected by HIV arrived at the "Instituto Médico Legal". They represented 0,3% of all the autopsies performed in this period. Of these cases, 55,7% were from natural death, 23,7% from suicide and 20,6% from homicide.

A.555

ESTIMATES OF THE AIDS EPIDEMIC IN COSTA RICA, 1989-1993

Mata, Leonardo*; Valadez, J.**; Marranghello, L.**,
*INISA, University of Costa Rica, San Pedro, Costa Rica;
**HIID, Harvard University, Cambridge, MA, U.S.A.; ***Ministry of Health, San José, Costa Rica.

Objective. To estimate the size and impact of the AIDS epidemic.
Methods. Five-year projections were obtained by fitting onto four statistical models all cases from epidemic onset in 1984 through December 1988.
Results. The data best fitted the power curve. Linear regression, exponential and logarithmic curves produced smaller R^2's and improbable case projections that are either too small or too large. 1) Epidemic in homo/bisexual men: the power curve projected 1989 cases (R^2=1) to be about twice those of 1988; thereafter, the doubling time likely increases. 2) Total AIDS cases: fitting by models yielded numbers lower than the number of cases already detected. 3) Total cases minus homo/bisexual cases: estimates were also low. The poor fitting of this subcategory of cases is accounted for by the early and now controlled epidemic in hemophiliacs, with occurrence of similar yearly number of cases, since 1984.
Conclusion. AIDS incidence in homosexuals is rising steadily, with no evidence to decline in the next decade. AIDS in hemophiliacs is not rising.

A.556

[illegible] INFECTION (HIV-1, HIV-2, HTLV-1) IN ASYMPTOMATIC WEST AFRICANS LIVING IN SPAIN

[illegible] [illegible], Tor J, Ribera E*, Fernandez JL**, Rego I, Foz M
Infectious Diseases and Blood Bank* Units. Hospital de Badalona "Germans Trias i Pujol", Universitat Autònoma de Barcelona. Hospital de Sant Jaume**, Mataró. Barcelona, Spain.

Objective. It has been postulated an African origin of Human T-lymphotropic retroviruses. While HIV-1 and HIV-2 produced AIDS, the HTLV-1 may be the etiologic agent of a subacute myelopathy and an acute T lymphocitic leukemia. However, the world widespread of these viruses may occur by infected African persons which have emigrated to developed countries. We studied the prevalence of HIV-1, HIV-2 and HTLV-1 antibodies in West Africans immigrants of Barcelona, an industrial region of Spain.
Methods. We studied 102 subjects (96 males and 6 females) who came from Gambia (50), Senegal (22) and Mali (29). They have been living in Barcelona since 1983. Mean age was 26.3. None of them referred risk factors for HIV infection, but more than 70% were heterosexual promiscuous, with frequent sexual intercourse with Spanish prostitutes. Antibodies to HIV-1, HIV-2 and HTLV-1 were investigated by ELISA and Western blot was used as confirmatory test in repeatedly reactive samples.
Results.

	HIV-1+	HIV-2+	HTLV-1+
ELISA	3	8	5
WESTERN BLOT	0	3	1

Conclusions. a) Presence of serological markers of HIV-2 and HTLV-1 infection (but not HIV-1) in asymptomatic West African residents in Spain. b) Heterosexually promiscuity is involved in all cases of HIV-2 and HTLV-1 positive men. As most of Spanish prostitutes are also intravenous drug abusers, we wish to draw attention to the possible role of prostitutes as transmitters of HIV-2 and HTLV-1 from subjects from endemic areas.

A.557

EVALUATION DE LA SUSCEPTIBILITE A LA PREVENTION DU SIDA CHEZ LES ETUDIANTS DES UNIVERSITES D'AIX-MARSEILLE

BERESNIAK Ariel*, ENEL P.*, SAMBUC R.*, SAN MARCO J.L.*
* Laboratoire de Santé Publique, Faculté de Médecine, Marseille, FRANCE.

Objectif : L'information est l'outil principal de la stratégie de prévention contre le SIDA. Une enquête d'évaluation de cette information a donc été entreprise chez les étudiants des Universités d'Aix-Marseille.
Méthodes : Un échantillon de 3.200 étudiants a été réalisé par la méthode des quotas en fonction des éléments statistiques des Universités (répartition par âge, sexe, année et type d'études). 3.200 questionnaires à volet de réponse anonyme ont donc été envoyés par courrier par l'organisme d'Assurance-Maladie couvrant ces étudiants. 844 réponses ont été exploitées.
Résultats : La population étudiante est informée principalement par les médias (87 %) et est très sensibilisée au risque de SIDA. Toutefois, leur comportement sexuel s'est peu modifié (73 %). 33 % possèdent des préservatifs mais seulement 8 % les utilisent toujours (fille ou garçon). Parmi ces 8 %, 79 % considèrent le SIDA comme une menace personnelle. Ceux qui n'utilisent qu'occasionnellement le préservatif sont plus nombreux (25 % des filles, 40 % des garçons). Les principaux défauts reprochés aux préservatifs sont tout d'abord la diminution de la spontanéité puis du plaisir. Enfin, 52 % des étudiants aimeraient bénéficier d'un dépistage gratuit et anonyme pour en connaître les résultats (84 %) et 75 % accepteraient de faire partie d'un groupe témoin subissant un test.
CONCLUSION : Nous récoltons les fruits d'un programme national de prévention basé sur l'information mais dont la réalisation a été anarchiquement monopolisée par les médias. Ceux-ci mélangent couramment les informations journalistiques aux informations à but préventif. Des efforts restent à faire pour coordonner toutes les sources d'informations afin d'aboutir à un programme cohérent qui gagnerait en impact.

A.558

THE HIV EPIDEMIC BEYOND THE EPICENTER: "INNER CITY" EPIDEMIOLOGY IN A PREDOMINANTLY WHITE SUBURBAN POPULATION

Sharp, David; Kaplan M; Smith M; Muggeo C. Cornell Univ. Medical College, North Shore University Hospital, Manhasset, NY, USA.

Objective. To characterize the epidemiology of HIV infection seen in a university-affiliated teaching hospital located in a suburban setting beyond the New York City limits in Long Island.
Methods. Hospital and clinic records of the Div. of Infectious Disease were used to create a computerized data base. Referral patterns were determined using home phone area codes.
Results. From 1981 to 1988, 808 patients with HIV infection were seen. 63% were from Nassau and Suffolk Co. (area 516), and 26% from Queens/Brooklyn (area 718). The characteristics of the group (in %) are as follows:

MALE	FEMALE	WHITE	NON-WHITE	GAY	IVDA	HETERO	TRANSF	CHILD	UNK
76	24	79	21	40	36	10	5	4	5

The population was predominantly white in all risk groups. However, 59/195 (30%) of women were non-white compared with 110/613 (18%) men (p<0.01) and 25/79 (32%) heteros were non-white compared with 144/729 (20%) with other risks (p=0.02). 68% of hetero cases occurred in women. No trends were discernible when case distribution was analyzed by year.
Conclusion. An epidemiologic pattern of HIV infection like that seen in non-white inner city populations, with an increased proportion of cases occurring in women, IVDAs and by heterosexual contact, is present in a largely white population drawn mostly from suburban Long Island. However, even in this setting, non-white women are over represented among heterosexual cases and in the group as a whole.

A.559

REGIONAL DIFFERENCES IN SURVIVAL WITH AIDS AMONG GAY WHITE MALES IN THE UNITED STATES

Piette, John*
*Brown University, Providence, Rhode Island; USA.

Objective. To examine geographic variation in survival with AIDS among gay white males in the United States.
Methods. Survival curves are calculated using data from a census of 24,668 AIDS cases reported to the Centers for Disease Control by 10/3/88. Analyses are presented by region and controlling for the presence of PCP. Randomly selected sub-samples of n=2,500 are used to calculate Mantel-Cox statistics testing for regional variations in survival.
Results. Median survival in the Northeast=20.8 months; median survival in all other regions is less than 15.6 months. Survival density functions are presented for all regions. Survival is shortened for cases with PCP, however, Northeast survival time is longer for both PCP and non-PCP cases. (Mantel-Cox chi-square w/4 df.=21.94;p=.0002) No differences are found in reporting bias or patient mix which explain the phenomenon.
Conclusion. Cases diagnosed in the Northeast survive significantly longer than cases diagnosed in other regions of the U.S.A.. Possible explanations include differences in the health care provided, patients' treatment preferences, and regional differences in the prevalence and severity of opportunistic diseases affecting persons with AIDS.

A.560

POSSIBILITIES OF FORECASTING HIV SPREAD IN LARGE POPULATIONS. A MODELLING TOOL FOR DECISION MAKERS

* MICHAEL G. KOCH, ** Dietrich Dörner, *** José J. Gonzalez, **** Johannes L'age-Stehr, ***** Pål Davidsen, ****** Ulrich v. Welck

* Vårdcentralen, S-546 00 Karlsborg, Sweden; ** Psychology II, University, D-8600 Bamberg, FRG; *** ASA, N-4890 Arendal, Norway; **** Robert-Koch-Institute, BGA, D-1000 Berlin 65, FRG; ***** Institute for Informatics, University, N-5007 Bergen, Norway; ****** ACS, D-8000 München 60, FRG.

In comparison between different methods of forecasting the development of an epidemic, computer based simulation techniques are well established and show several advantages, among them high speed, flexibility, transparency, and reproducibility.

The program "AIDS Spread Simulations and Projections" (ASSP) is a modelling tool and was elaborated under the years 1985-1988. The user's interface is didactically guiding and does not require special mathematical knowledge. It is, adapted to a personal computer of good standard (IBM AT or compatible), used by several health authorities since early 1988. The principal structure of the program and possible applications are described.

A.561 CORRELATION OF INCUBATION PERIOD AND PROGRESSION TO DISEASE IN HIV CARRIERS

* MICHAEL G. KOCH, ** Pål Davidsen, *** Ulrich v. Welck, **** José J. González

* Vårdcentralen, S-546 00 Karlsborg, Sweden; ** Institute of Informatics, University, N-5007 Bergen, Norway; *** ACS, D-8000 München 60, FRG; **** ASA, N-4800 Arendal, Norway.

Comparing about 90 different clinical follow-up studies from various regions in the world, we tried to define the progression rates of HIV infected persons to AIDS. The main problem is that different patient groups never are fully equivalent concerning important variables as their distribution into age and risk categories. Although a point of time may be known, when they were infected, it is usually unknown, when exactly they got infected. Comparing various studies, the co-factor time shows to dominate and to explain the apparent inconsistency of results referred by different authors. The shape of the probability distribution of incubation periods seems to be influenced by a continuous malignification of the dominating virus strain in the host, a feature we do know as enhancement of pathogenicity by repeated host passages, here, intraindividually, speeded up to a regularly occuring event by selective pressure due to the rapid antigenic drift of lentiviruses and their tendencially changing receptor tropism.

A.562 HIV SEROPREVALENCE AT COOK COUNTY HOSPITAL, CHICAGO: A TWO-YEAR FOLLOW-UP

Seibert, D. *; Taul, P.**; Cohen, M.*; Nash, A.***; Sherer, Renslow.* et.al.
* Cook County Hospital AIDS Prevention Service; ** Cook County Hospital Blood Bank; *** Cermak Health Services, Cook County Jail. Chicago, Il, U.S.A.

Objectives. To determine the prevalence of HIV infection among persons at risk of HIV infection at Cook County Hospital, Chicago, in 1987 and 1988, and to compare trends among groups at risk.
Methods. From 1/1/88 to 12/31/88, 2,084 clients received HIV antibody counseling. Demographics: 42% women, 58% men; 69% black, 15% Hispanic, 15% white. Of 2,084 persons counseled, 1,146 (55%) were tested in 1988; in 1987, 1,042 people were counseled and 522 (50.0%) were tested. Two positive EIAs and a positive Western Blot were considered positive. Class IV HIV infection was excluded.
Results. Table I shows the results: TABLE I * - to be presented

	1987			1988		
	N	POS	%	N	POS	%
GAY/BISEX	181	110	60.8	*	98	*
GAY/BI IVDU	15	11	73.3	*	7	*
IVDU	200	66	33.0	*	121	*
HETERO PARTNER AT RISK	50	12	24.0	*	9	*
TRANSFSN RECIP	10	3	30.0	*	0	*
MULT HETERO PARTNER	66	6	9.1	*	33	*
PEDIATRIC - MTHR AT RSK	10	3	33.3	*	4	*
TOTALS	522	208	39.8	1,146	272	23.7

Of those positive in 1988, 181 (82%) were male, and 31 (18%) female. By race, 181 (66.5%) were black, 55 (20.2%) Hispanic, and 34 (12.5%) white. Four (1.5%) were newborn & 31 (11.4%) were 18-24.
Conclusions. Overall, a 30.7% increase in HIV seropositivity was observed from 1987-1988. Increased access to HIV counseling and testing resulted in a 170.3% increase in HIV seronegative persons at risk counseled. Increased numbers of infected IVDUs and heteros were identified.

A.563 WOMEN WITH AIDS: A CONTINUING STUDY 1988

Kloser, Patricia; Bais, P.; Lynch, A,; Lombardo, J.; Kapila, R. University of Medicine and Dentistry of New Jersey, Newark, New Jersey, USA.

Objective: To describe the epidemiology and natural history of HIV infection in women in Newark, New Jersey.
Methods: This is a continuation of our study of women with HIV disease started in 1980. The addition of 174 new cases in 1988 makes a total of 538 women seen with HIV infection at our facility.
Results: The women represent the population of the area surrounding our hospital (Newark has been described as the poorest large city in the US), with 156 (89.6%) Black, 13 (7.5%) Hispanic and 5 (2.9%) White. Their age range was 19-55 with 1 (.6%) less than 20, 42 (24.1%) aged 20-29, 106 (60.9%) aged 30-39, 21 (12.1%) aged 40-49 and 4 (2.3%) aged 50-55. Their risk for infection was IVDA in 105 (60.3%), hetrosexual exposure in 37 (21.3%), unknown in 29 (16.7%) and transfusion in 3 (1.7%). Of 46 documented opportunistic infections (OI) 22 (47.8%) were PCP, 13 (28.3%) tuberculosis, 6 (13.3%) cryptococcal meningitis, 4 (8.9%) toxoplasmosis and 1 (2.2%) lymphoma. There were 25 deaths in 1988 with an average age of 34.1 years. The average length of time from diagnosis to death was 15.5 weeks with a range of 2 days to 44 weeks. (14.5 weeks - 1987).
Conclusion: This is the first year that the number of new cases is not much increased from the previous year (169 new cases in 1987). PCP and tuberculosis remain the most common OI. Of concern is the increased number of deaths in 1988 (20 in 1987) and the continued short time span from diagnosis to death in the inner-city woman.

A.564 SURVEY OF STREETWALKING PROSTITUTES IN NEW YORK CITY FOR ANTI-HIV-1 ANTIBODIES

Wallace, Joyce I.* and Beatrice, S.**; *Foundation for Research on Sexually Transmitted Diseases, New York, NY, USA and **New York City Department of Health, New York, NY, USA.

Objective. To determine the rates of HIV-1 exposure in streetwalking prostitutes of New York.
Methods. In 1985-1988 prostitutes working on the streets of New York City were tested for anti-HIV-1 antibodies. Blood was drawn on-site, and was tested for antibodies by ELISA with Western Blot confirmation. The women were queried as to their ages, number of years worked, and histories of risk behavior: including history of transfusions, intravenous drug use, or lovers who were known to be intravenous drug users.
Results. The rates of positivity declined from 1985 to 1988.

	1985	1986	1987	1988
Number HIV-1 Positive	4 (19%)	4 (9%)	4 (6%)	2 (5%)
Total Number of Samples	22	43	67	37

A total of 169 women were examined, of whom 14 (8.9%) were found to be infected. Of the 20 (12%) who admitted to intravenous drug abuse, 6 (30%) were positive. Of the 149 (88%) who denied intravenous drug use, 8 (5%) were positive. In 1982, a similar survey of T_4/T_8 cells among women who worked the brothels and the streets of New York City, showed a rate of 19% immune deficiency.
Conclusions. Although there has not been an increase in the rate of infection among prostitutes, there remain significant numbers (as many as 5%) of infected women working the streets. An in-depth study and program of outreach to prostitutes in all of metropolitan New York City will begin in March of 1989.

A.565 *EFFECT OF AGE ON AIDS ATTACK RATE IN HEMOPHILICS IN CALIFORNIA*

Gomperts, Edward; Holman, R.**; Jason, J.**; Evatt, B.**; Addiego, J.***; Hartman, G.***; Lewis, B.***; Glader, B.***; Katz, J.***; Dietrich, S.***; Abildgaard, C.***; Koerper, M.***; Anderson, H.***; Sun, T.***. *Childrens Hospital of Los Angeles, Los Angeles, California; **CDC Host Factors Division, Centers for Disease Control, Atlanta, Georgia; ***The California Hemophilia Study Group,* CA, U.S.A.

Comprehensive Care is provided to 90% of hemophiliacs in California by 13 Centers. For the year 1987, these centers reported on patient HIV antibody status, age of patient, level of clotting factor deficiency and hemophilia type. The number of AIDS cases in California for the purposes of this study, was that reported to the CDC to 12/31/1987. The increase by age groups in the HIV positivity rate and AIDS rate was statistically analysed. HIV serological status was reported on a total of 1438 individuals with hemophilia A and B. Of these there were 860 individuals (59.8%) whose serological status was known: 537 known a-HIV positive patients (62.4%), 323 negative (37.6%) and 578 patients (40.2%) had not been tested. The attack rate of AIDS is defined as the number of cases of AIDS patients reported as compared with the number HIV positives. This rate for the group as a whole was 11.5% or 62 cases among 537 seropositives; 14.6% (54 in 527) for those patients over 21 years of age and 4.8% (8 in 167) for those under 21 years (p .001). Despite an equivalent distribution of the date of diagnosis of AIDS, there was a bimodal distribution in the rate of AIDS among the age groups with the 6-12 year old and > = 21 year age group showing higher frequencies than those in the 13-20 age group.

A.566 PREVALENCE OF ANTI-HIV IN I.V. DRUG USERS OF LATINA PROVINCE,ITALY.

Perroni Luigi,LeFoche L.,Mercurio V.,Tacconi L.,Zanini R.andSoscia F.
Dept.of Infectious Diseases, Latina General Hospital,Latina.Italy.

Objective.To investigate the prevalence of HIV infection in i.v. drug users (i.v.d.u.) and to assess the distribution of other know risk factors.
Methods.All the i.v.d.u. attending public methadone maintenance clinics in the province of Latina,were offered the HIV antibody test.
Subjects repeatedly HIV positive (Elisa Abbot) confirmed by Western Blot (W.B.) were also tested for Hepatitis B markers and for syphilis (VDRL,FTA,-TPHA).History and clinical examination were performed to detect presence of genital warts and other sexually transmitted diseases (S.T.D.).
A standardized questionnaire with questions on sexual preferences, number of sexual partners,prostitution, needle sharing was submitted to them.
Results.Results are shown in table; 90% often shared syringes,while 20% had 3 or more sexual partners in the previous year,5% were omo-bisexual and 3% were prostitutes.

i.v.d.u.	tested	HIV+	HBsAg+*	HBsAb+*	VDRL/FTA/TPHA*	S.T.D. (*of 302 HIV+)
1203	658	302	25	140	16	24

Conclusion.Our data show the high prevalence of HIV infection in i.v.d.u. in our province.The high frequency of needle sharing is noteworthy.
The possible contributory role of sexual at risk habits to HIV transmission in i.v.d.u. should be further investigated.

A.567

36 MONTHS FOLLOW-UP OF HIV-1 SEROPOSITIVE INDIVIDUALS

I.Mezzaroma, C.Papetti, A.M.Pesce, G.D'Offizi, E.Pinter, G.Luzi and F.Aiuti

Dept. of Allergy and Clinical Immunology, University of Rome "La Sapienza", Rome, Italy.

Objective - To evaluate the re-classification risk in HIV-1 seropositive patients at various clinical stages according to the CDC system.
Methods - Patients belonging to at risk categories were included: 25 homosexuals, 211 drug addicts, 22 heterosexuals. They were classified at the first medical check according the CDC system: 40 CDC-II, 218 CDC-III. Selected patients were admitted to a follow up protocol (24 and 36 months). Every 6 months a clinical up date was performed.
Results - The percentage of re-classified patients is as it follows

from CDC-II

CDC	6	12	24	36
II	100	89	64	42
III		11	29	14
IVA			3	22
IVC1			2	12
IVC2			2	10

from CDC-III

CDC	6	12	24	36
III	100	90	73	70
IVA		2	8	10
IVC1		1	5	7
IVC2		7	14	13

Conclusions - Immunological features and clinical evolution show that a high risk population is included in CDC-II patients, who appear less stable during the follow up (58% evoluted if compared with 30% of CDC-III).

A.568

ABSENCE ACTUELLE DE HIV2 A BRAZZAVILLE(CONGO)

P.YALA*, M.BIENDO*, J.MADZOUKA*, N.COFIN*, B.CARME*
*CHU BrazzavilleBP32 , Brazzaville, Congo.

OBJECTIFS: Contribution à épidémiologie de HIV2 en Afrique, à étude de réactions croisées HIV1 et HIV2.

METHODES: Dans 1022 sérums de malades, sélection selon critères Bangui, et 573 sérums de donneurs de sang: détection d'anti HIV1 et anti HIV2 par ELAVIA I et II et confirmation(quelques sérums) par LAV BLOT I et II.

RESULTATS: 1°- ELISA: 1.1-Malades: HIV1+ et HIV2- = 490/1022(47,9%);HIV1 + et HIV2 + = 26/1022(2,5%); HIV1 - et HIV2+ = 34/1022(3,3%).- 1.2-Donneurs de sang: pour mêmes tests successivement:20/573(3,4%); 28/573(4,8%) 79/573(13,78%). 2°- WESTERN BLOT: avec HIV1: Chez malades: 62/64(96,8%); profil fréquent: Env: GP160, GP110, GP41; Core: P18, P25, P34, P40, P55, P68. Un seul cas de perte de P25.Chez donneurs de sang: 25/48(52,08%) confirmés, mais 16/48 réactions seulement avec 1 ou 3 protéines du Core: P18, P25, P34, P40, P51, P55. 7/48: aucune réaction. Avec HIV2: ni chez malades, ni chez donneurs de sang aucune protéine Env(GP36/41, GP105/130) n'a donné de réaction. Mais 31/64(48,4%) : réactions croisées avec core (1 ou plusieurs protéines): sur 31 cas, P36 trouvé 30 fois(96,7%), P26= 19(61,2%), P41 = 8(25,8%), P6 et P56= 1fois chacun(3,2%).

CONCLUSIONS: a)- HIV2 actuellement absent à Brazzaville, mais nombreuses réactions croisées(nécessité de tests de discrimination).b)-Confirmation de réaction croisée dans Core. c)- Problèmes de faux positifs en transfusion. d)- Perte de P25 rare chez nos malades.

A.569

HETEROSEXUAL TRANSMISSION OF HIV INFECTION IN A GROUP OF POPULATION OF MADRID CITY

Ortíz, Carmen; Babín, F; Andreu, P; Bru. F; Pascual, I; Colomo, C.;
C.P.S. Centro, Madrid Council , Madrid, Spain.

Objective. Epidemiological study of HIV infection in 318 subjects with the only risk of heterosexual transmission.
Methods. Computerized data of Internal Medicine and Dermatology Units of the Clinic were used for the analysis. Twenty two social and sanitary parameters of 318 patients (51 men and 267 women) were followed during two years.
Results. The incidence of HIV infection was of 26 cases (8,17%), (21 cases of stage II, 2 cases of stage III and 3 cases of stage IV). In the study of concomitant disease, of HIV infected patients, oral candidiasis and seborreic dermatitis were found statistically significant.
Anal intercourse was the only risk habit found with statistically significant differences. Low use of condom in HIV infected (23,07%) and seronegative patients (20,54%) was also observed.
Conclusion.

- The results are similar to others obtained in other big cities
- Condom use must be a great task for health professionals, and more knoledge is needed in health are education to improve the use of preventive methods.

A.570

SAFE AND UNSAFE SEXUAL PRACTICES AMONG HOMOSEXUAL MEN, AND THE RISK OF HIV INFECTION

Messiah Antoine*, Bucquet D***, Rouzioux C**, Mosnal J-F**. *INSERM, **Hôpital Necker, Paris ; ***INSERM Montpellier, France.

Objective : To assess the risk of HIV infection among homosexual men, with regard to safe and unsafe sexual practices.

Methods : Cross-sectional study among 300 homosexual outpatients of general practitioners and venereologists of the Paris area. The subjects were of unknown or of previously negative serological status. Before being tested, they were ask to fill a self-administred questionnaire, which focused on frequencies of protected and unprotected sexual practices ; for protected ones, the frequency of lubricant use was asked, since oily-based lubricants might have damaged the condom. To adjust for previously established risk factors, i.e. promiscuity and unprotected anal receptive intercourse, the comparisons were made using the Mantel-Haenszel procedure. Significant variables were then tested using a logistic regression.

Results : Practices associated with seropositivity were : protected anal receptive intercourse with lubricant (base unspecified) ; receptive ano-oral sex ; and rectal douching after sex. Practices not associated with seropositivity were : insertive and receptive genito-oral sex ; protected anal receptive intercourse without lubricant. Forty percent of the subjects used oily-based lubricants.

Conclusion : Reducing promiscuity and unprotected anal intercourse would not seem to achieve total prevention of infection. The use of oily-based lubricants with condoms and rectal douching after sex should be avoided.

A.571

UNE CLASSIFICATION CIM-9 POUR LES INFECTIONS PAR LE VIH L'EXPERIENCE FRANCAISE EN MORBIDITE HOSPITALIERE

BOULAY Fabrice*, PIBAROT ML.*, JESTIN C.**, LAPORTE A.***, BRUNET JB***.

* Direction des Hôpitaux. ** Service des Statistiques, des Etudes et des Systèmes d'Information. *** Direction Générale de la Santé. Ministère de la Santé. Paris. France.

Objectifs : Evaluer de nouveaux codes CIM-9 pour les infections VIH en morbidité hospitalière.
Méthodes : Par rapport aux codes nord-américains, la version française a été simplifiée et actualisée (définition OMS 1988). Les codes des diagnostics principaux et secondaires de 3 911 hospitalisations (court séjour et hôpital de jour) réalisées dans 16 centres de référence durant l'année 1988, ont été analysées pour juger de l'utilisation de ces nouveaux codes.
Résultats

	N	%	
044.0 Infection aigue	19	0.5	
.8 Asymptomatique	862	22.1	24.2
.9 Infection VIH.SAI	64	1.6	
043.0 Lymphadénopathie	609	15.6	32.6
.3 Autres formes mineures	663	17.0	

SIDA avéré avec :	N	%	
042.0 Infections opportunistes	834	21.3	
.2 Tumeurs malignes	130	3.3	
.3 Troubles neurologiques	56	1.4	
.4 Troubles généraux	183	4.7	43.2
.7 Affections multiples	462	11.8	
.8 Autres affections	16	0.4	
.9 SAI	13	0.3	

Les codes Sans Autre Indication (SAI) sont très peu utilisés (1.9 %) et concernent fréquemment des SIDA pédiatriques (6/13). Le code 042.8 est utilisé pour les pneumonies interstitielles lymphoïdes (7/16). Deux codes particuliers à la version française (042.7, 043.3) sont précisés : 1) en cas d'affections multiples (042.7), on note toujours une infection opportuniste (pneumocystose 51.3 %, toxoplasmose cérébrale 18.1 %, cytomégalovirus 15.6 %, candidose oeso-trachéo-bronchopulmonaire 13.4 %) souvent associée à un Kaposi (32.7 %) ; 2) les autres formes mineures (043.3) sont pour 56.3 % des infections (candidoses 53.5 %, zona 20.6 %) et pour 28.7 % des affections immuno-hématologiques (thrombocytopénies 71.4 %, agranulocytoses 19.9 %).
Conclusion : Ces codes CIM-9 apparaissent adaptés à la morbidité hospitalière.

A.572

EVALUATION OF A PEDIATRIC AIDS OUTPATIENT PROGRAM.

Perez-Alvarez,Teresa; Merodio, C.; Babín, F.; Andreu, P.; Quintero, Y.; Vivar, P.

C.P.S. Centro. Madrid Council. Spain.

OBJECTIVE: To evaluate the children's AIDS program carried out in an outpatient clinic located in the "Centro" district of Madrid city.

METHODS: 130 children ranging from the age of 15 days to 13 years were studied. Biological and psychosocial parameters were analized.

RESULTS: 108 children (83%) were seronegative and 22 (13%) had antibodies at any time of their. All seropositives children had seropositive mothers. 33 per cent of the 12 children over the age of 15 months, are infected (7,3,4, and 4 years of age). All except one of them of 4 years (P2-A), are asythomatics after 18 months of follow-up. Two children were not followed-up.

Of those infants under 15 months, 20 per cent (2) became seronegative and 80 per cent (8) are still seropositive.

No one of the 86 children living with seropositive adults, and sharing house hold goods (57% of these considered risk goods), were infected

CONCLUSIONS: A diminution of the incidence of HIV infection in children over the age of 15 months, was observed.

The lack of transmission in house holders.

To emphasize the importance of biologic and social factors in health state of these children.

The low rate of abandonment of the program as it was carried out in an outpatient clinic in the community.

A.573

FIRST CASE OF HIV1/HIV2 INFECTION IN CAMEROON

KAPTUE, L.* ; ZEKENG, L.** ; NGU, K. ** ; OUATTARA, A*** ; MONNY-LOBE, M. **** ; SALLA, R. *.
* NATIONAL AIDS COMITTEE YAOUNDE, CAMEROON ** UNIVERSITY TEACHING HOSPITAL YAOUNDE, CAMEROON *** INSTITUT PASTEUR, ABIDJAN, COTE D'IVOIRE
**** CENTRAL HOSPITAL, YAOUNDE, CAMEROON.

Objective. To report the first case of HIV1 and HIV2 infection diagnosed in a cameroonian patient. Up till june 1988, 6 000 sera were screened for HIV2 antibodies and all were found negative.

Methods. Systematic screening of patients referred to the University teaching Hospital, using Elisa test (Behring HIV1 and Elavia2) and Western Blot (Dupont and Diagnostic Pasteur) for confirmation.

Results. A 28 years old patient referred for prolong fever, weight loss and oral candidosis was recently found HIV1 and HIV2 positive. Looking at the past medical history, the patient had frequented West Africa.

Conclusion. From this case study, we should start thinking about the presence of HIV2 in Cameroon, considering the frequent movement of people between neighbouring countries.

A.574

HIV SPREAD IN PROSTITUTE POPULATION IN TOULOUSE (FRANCE)

Gayet-Mengelle C.*, Puel Jacqueline*, Averous S.**, Bazex J.**
*Laboratoire de Virologie, CHU Purpan;
**Service de Dermatologie, CH La Grave, Toulouse, FRANCE.

Objective. To assess the risk of contamination through prostitution (male or female) in our city.
Methods. We systematically screened anti HIV-1 antibodies in 97 female prostitutes (9 coming from Ghana) and 16 travestites or transsexuals, regularly consulting at the Venereal Diseases Centre since May 1985, to January 1989. Screenings were realised using 2 immunoenzymatice techniques (Abbott and Wellcome). All positive sera were confirmed by the Western-blot assay (Du Pont De Nemours)
Results. 5 of the 97 prostitutes were seropositive : we screened the first one in 1985, two others in 1986, one in 1987, and one who seroconverted in 1988. But two of them were intravenous drug abusers, so it was not possible to incriminate sexual transmission with certainty. None of the Ghanean was seropositive. Among the travestites and transsexuals, one patient seroconverted in 1985, and 3 patients were seropositive (2 in 1986 and 1 in 1987). For these patients drug addiction is unknown.
Conclusion. The prostitute population of Toulouse seems to be relatively free of HIV-1 contamination. But these results do not entirely reflect the true situation as a marginal prostitution also exists with people who are generally not subject to any control. Although these results are relatively reassuring, elementary precautions must be taken to prevent the spread of the disease, since contamination through prostitution has been shown to be a real risk.

A.575

THE NEW CASE DEFINITION CRITERIA, ITS IMPACT ON EPIDEMIOLOGICAL SURVEILLANCE IN SPAIN.

De Andrés, Rafael*; Tello, Odorina**; Madrano, Mª José**.
* Secretaría General del Plan Nacional sobre el SIDA;
** Subdirección General de Información Sanitaria y Epidemiología, Madrid Spain.

Cumulative AIDS cases in Spain on date December 21st. 1988 are 2165. Modifications of case definition criteria for reporting AIDS were undertaken in August 1987 by CDC, accepted by WHO in September and applied by the European countries since January 1st 1988. We have studied the impact of these new criteria of case definition among cases diagnosed in Spain since 1981. Since January 1st. 1988 a 72.58% case increase has been detected applying the new criteria of case definition in respect to the old ones. By the new criteria the retrospective revision of cases diagnosed before this last date classified as no AIDS by the old criteria means a 13.19% increase in 1984, 10,76% in 1985, 13,88% in 1986 and 30.13% in 1987. This impact is clearly higher among IVDU (47,34%) and children born from mothers at risk (58.33%) than in the homosexual transmission category (17.27%). The impact is also different by pathological and transmission categories. Kaposi sarcoma is increased 1.29% in the homosexual transmission category and 4.76% among the IVDU. Nevertheless, a 22.56% increase associated to opportunistic infections is detected in the homosexual transmission (800% increase associated to extrapulmonar tuberculosis) 26.93% among IVDU (7,900% increase associated to tuberculosis extrapulmonar), a 10.00% in the heterosexual transmission category and 47.22% among children born from mothers at risk. Conclusions: 1) Different impact is observed in different country areas in respect to pathological background and epidemiological pattern. 2) The relevance of these results is important for epidemiological analysis, trends and predictions. 3) This different impact should be considered by Publich Health strategies and policies on people's perception about the case number increase.

A.576

PREVALENCE OF DIFFERENT RETROVIRUS IN SPANISH INTRAVENOUS DRUG USERS DURING 1.987-1.988. CLINICAL FINDINGS OF SEROPOSITIVES.

Contreras G., Garcia Saiz A., Vallhonrat E., Varela J.M., Peres Alvarez L., Najera R. Instituto de Salud Carlos III, Madrid, Spain.

OBJETIVE.- To analyze the seroprevalence of HIV-2 and HTLV-I in spanish intravenous drug users (IVDA) and the clinical findings of seropositives to HIV-1 in relationships to the antigenemia status. We determine as well — the incidence of coinfection with other infectious agents.

METHODS.- Sera collected from 4.269 IVDAs were tested (1.888 in - 1.987 and 2.381 in 1.988). The presence of anti-HIV-1, -HIV-2, -HTLV-I antibodies was revealed by ELISA. IFA and WB was used as a confirmatory test. — Antigen ELISA test was used for HIV p24 antigen detection.

RESULTS.- The prevalence of HIV-1 was 64,7% in 1.987 and 61,9% in 1.988. Data collection are ongoing and analysis suggests up to date that a - 70% of seropositives still asyntomatic and a 30% shows some patology related with HIV infection. We are currently performing the seroprevalence of anti-HIV-2 and HTLV-I in a group of IVDAs with statistic significance. A 8% shows HBsAg and a 2,5% active syphilis.

CONCLUSION.- The prevalence rate, about 60% during 1.987 and 1.988 and similar to previous years, is high enough to indicate a serious problem of HIV infection among the spanish drug users. Very preliminary results indicate no incidence of HIV-2 and HTLV-I in this IDVA population.

A.577

CONTROL OF HIV TRANSMISSION IN THE NATIONAL BLOOD BANK IN MALI

M. K. Maiga, S. Traore, A. Guindo, O. Fofana, Comité de lutte scientifique et technique contre le SIDA, Bamako, Mali.

Since the beginning of the national AIDS program in Mali in 1987, the national blood bank was one of the strategic points for detection, prevention of the transmission of the human retrovirus and the follow up of the prevalence of HIV infection among blood donors. Blood donation was performed from pregnant women, young military recruits and students. Consecutivly in 1987 a total of 1140 blood samples and in 1988 a number of 1841 were tested using "Rapid Elisa mixt" to detect HIV1 and HIV2.

The positive samples were then confirmed by Western Blot.

Results : A steady increase in the seroprevalence of HIV infection was observed. Among 1140 sera in 1987, nineteen (19 = 1.66 %) and 1988 out of 1841 sera, seventy six (76 = 4.1 %) were found positive. This represent a total increase of 256.25 % in one year.

Conclusion : In both years the studied cohort was not randomised and and is not representative of the Malian population. Allthough in the country the infection rate is generally low, an evidence of rapid expansion of the epidemic is demonstrated in this study. Beside dispositions undertaken for transfusion of safe blood only, a large restructuration program has started which intend to improve the technical basis and conservation of blood.

Thus the efforts of the national AIDS committee to prevent the transmission of the retrovirus should be activly reinforced.

A.578

THE NEW CASE DEFINITION CRITERIA, ITS IMPACT ON EPIDEMIOLOGICAL SURVEILLANCE IN SPAIN. De Andrés, Rafael*; Tello, Odorina**; Madrano, Mª. José**.
* Secretaría General del Plan Nacional sobre el SIDA;
** Subdirección General de Información Sanitaria y Epidemiología, Madrid, Spain.
Cumulative AIDS cases in Spain on date December 21st. 1988 are 2165. Modifications of case definition criteria for reporting AIDS were undertaken in August 1987 by CDC, accepted by WHO in September and applied by the European countries since January 1st 1988. We have studied the impact of these new criteria of case definition among cases diagnosed in Spain since 1981. Since January 1st. 1988 a 72.58% case increase has been detected applying the new criteria of case definition in respect to the old ones. By the new criteria the retrospective - revision of cases diagnosed before this last date classified as no AIDS by the old criteria means a 13.19% increase in 1984, 10,76% in 1985, 13,88% in 1986 - and 30.13% in 1987. This impact is clearly higher among IVDU (47,34%) and children born from mothers at risk (58.33%) than in the homosexual transmission category (17.27%). The impact is also different by pathological and transmission categories. Kaposi sarcoma is increased 1.29% in the homosexual transmission - category and 4.76% among the IVDU. Nevertheless, a 22.56% increase associated to oportunistic infections is detected in the homosexual transmission (800% increase associated to extrapulmonar tuberculosis, 26.93% among IVDU (7,900% increase associated to tuberculosis extrapulmonar), a 10.00% in the heterosexual transmission category and 47.22% among children born from mothers at risk. Conclusions: 1) Different impact is observed in different country areas in — respect to pathological background and epidemiological pattern. 2) The relevance of these results is important for epidemiological analysis, trends and predictions. 3) This different impact should be considered by Publich Health — strategies and policies on people's perception about the case number increase.

A.579 AIDS IN THE NORDIC COUNTRIES - PREVENTION AND CONTROL

Westphal-Christensen, B.*; Bjørner, J.**; Eriksson, B.***; Krasnik, A.**.
*Danish Institute for Health and Nursing Research, Copenhagen, Denmark, **Inst of Social Medicine, Copenhagen, Denmark, ***Nordic School of Public Health, Göteborg, Sweden.

Psychological, social, administrative and political aspects of AIDS in the Nordic countries have been reviewed by the Nordic School of Public Health.

As expected, the countries appear quite similar. Specified AIDS-commissions have been established, closely linked to governments. Specific target groups like homosexuals have been involved in preventive activities. Health education has been depicted the most important issue to combat AIDS. Large campaigns have been launched directed to the general public and towards groups like school children and health personell. Knowledge about AIDS has been seen to be generally good and improving. Systematic knowledge about sexual behaviour, however, is virtually nonexisting. Donated blood and organs are compulsorily tested. Anyone person can have a test and remain anonymous except in Iceland where the person has to identify himself at the test site, but is reported by code.

Treatment and care is similar in the Nordic countries basically handled by the health authorities. Voluntary and private organisations are, however, more important than generally in the health sector.

Differences exist in legislation. In Sweden and Iceland HIV-infection is under the law for sexually transmitted diseases. In Finland, it is a notificable disease while there are no specific legislation concerning HIV-infection in Denmark and Norway.

A.580 RISK PROFILE FOR HIV INFECTION AT A SEXUALLY TRANSMITTED DISEASE CLINIC.

Beidas, Sary *; LoConte J.**; Byrnes D.**. *Saint Michael's Medical Center, **East Orange Health Department, Newark, N.J.,U.S.A.

Objective. To determine HIV risk profile of HIV infected individuals in an STD clinic population, and coexisting STD's at time of diagnosis.
Methods. One hundred and forty patients were counselled and tested for HIV antibody, at an inner city STD clinic over a 7 month period. Thirteen (9 %) patients tested positive for HIV antibody by ELISA and Western Blot. Due to anonymous testing only 6 patients could be identified for post testing counselling and follow up.
Results. All 6 patients were males, mean age 29.2 ±7.4(SD) years. Risk factors identified were : Intravenous Drug User, 5 (39 %) patients; Homosexuals, 4 (31 %) patients; Sex with prostitute, 2 (15 %) patients; Intravenous Drug User and Homosexual, 1 (7 %) patient; Unknown, 1 (7 %). Four homosexuals had syphilis with an RPR titer ranging between 1 : 8-4096. 1 patient had a rising RPR titer despite treatment with I.M Penicillin (total 7.2 million units). 3/6 patients had evidence of an ulcer or skin breakdown at the time of diagnosis.
Conclusion. The above data suggest that the majority of patients identified with HIV infection in an STD setting are still within a recognised high risk group. However sexual behaviour patterns need to be modified in order to limit heterosexual transmission. Patients with genital area skin breakdown appear to particularly be at increased risk for acquiring syphilis and HIV infection.

A.581 Evaluation of a multidisciplinary HIV diagnosis anc management centre, Sydney, Australia.

Morlet, A.; Michelmore, Harry; Turbitt, P.; Begley, K.; Gold, J.
Albion Street (AIDS) Centre, Sydney Hospital, Sydney, Australia.

Objective: To provide a multidisciplinary diagnosis, ambulatory care and early intervention service for persons infected with HIV.
Method: The Albion Street (AIDS) Centre, established in March 1985, is staffed by 45 full time professional and support staff including doctors, nurses, counsellors and research officers. The Centre provides free and confidential pre and post-test counselling, HIV antibody testing, medical management of HIV related signs and symptoms, referral and emotional support groups. A computer based medical record system was developed and implemented to enable management of ongoing epidemiological surveillance, evaluation of risk education programmes and early intervention drug trials.
Results: To the end of December 1988 a total of 11340 clients had been tested at the Centre, 9049 male, 2259 female, 24 transsexual or unknown, 1179 intravenous drug users and 401 prostitutes. Of the total 1448 (12.8%) were diagnosed as HIV antibody positive, 1365 (94%) were homosexual or bisexual. 36 (5.6%) of the heterosexual intravenous drug users and 7 (1.5%) of blood transfusion recipients tested were infected. Over 70% of cases initially diagnosed by private physicians.
Conclusion: The comprehensive and specialised services provided by the Centre have resulted in it becoming the major referral clinic for management of early HIV infection. The Centre provides an early diagnosis and management model that facilitates effective implimentation and evaluation of intervention strategies aimed at slowing disease progression.

A.582 VIRAL HEPATITIS B(HBV)AND AIDS IN RISK COMMUNITIES IN THE NORTH-EAST OF ARGENTINA(NEA)

Fay,Oscar* **;Biglione,J**;Fernández,E*;Galíndez,J**;Guagnino,L**;Navarret,N**,et al.
*Centro de Tecnología en Salud Pública,UNR;**Comité Prevención SIDA,Rosario, Santa Fe,Argentina.

Objective. To study the attack rate of HBV and HIV in drug addicts(IVDA)and homosexuals(HS),compared with the general population as per samples collected from voluntary blood donors(VBD).
Methods.Studies were made on samples from communities seeking medical advice in response to COPRES appeal.HBV-carriers were differentiated thru ELISA HBsAg and previously infected ones, thru ELISA anti-HBc. All sera were searched for HIV thru ELISA and confirmed thru immunoelectrotransference(WB).
Results.

Community	HIV	(No)	HBsAg(+)	%	Anti-HBc(+)	%
IVDA	(+)	(154)	16	(10)	90	(58)
	(-)	(373)	32	(8.6)	231	(62)
TOTAL		527	48	(9.3)	321	60
HS	(+)	(43)	3	(7)	32	(75)
	(-)	(408)	28	(7)	306	(75)
TOTAL		451	31	(7)	338	75

Conclusion.HBV-infection is 5 to 8 times more frequent in the above risk population than among VBD in the NEA. HBV attack rate is higher among HS than among IVDA. HBV-chronic carriers were found more often among IVDA than among HS. There are more HBV-chronic carriers among HIV+IVDA than among HIV+HS. If IVDA samples are received in blood banks as VBD ones, HBV transmission risk will grow accordingly, unless adequate controls are implemented. HIV presence is not statistically significant to determine HBV presence in each population.

A.583 LYMPHADENOPATHY IS A WEAK PREDICTOR OF CLINICAL OUTCOME IN HIV INFECTION

Lang, William*; Anderson, R.**; Royce, R.***; Shiboski, S.***
*Children's Hospital, San Francisco, CA, USA; **ViRx, Inc., San Francisco, CA, USA; ***University of California, Berkeley, CA, USA.

Objective. To determine the relationship of lymphadenopathy to clinical outcome in HIV infection.
Methods. Lymphadenopathy was measured by trained examiners in a population-based sample of 385 men from the San Francisco Men's Health Study who were seropositive at entry in Fall 1984. The incidence of symptoms of progressive HIV infection and of AIDS were determined at 42 month's follow-up.
Results. The presence of ≥2 extrainguinal nodes ≥1 cm and the presence of total peripheral lymphoid mass ≥ 10 cm were both associated with slight but not statistically significant increased risk of developing both HIV-related symptoms and AIDS.

Risk of:	Symptoms	Odds Ratio (95% CI)		Odds Ratio (95%CI)
< 2 Nodes	31/83 (37%)	1.4 (1.0-1.9)	14/98 (14%)	1.5 (0.9-2.6)
≥ 2 Nodes	121/232 (56%)		63/285 (22%)	
< 10 cm	78/159 (49%)	1.3 (1.0-1.7)	38/192 (20%)	1.5 (0.9-2.4)
≥ 10 cm	31/47 (66%)		18/60 (30%)	

In a multiple regression analysis controlling for CD-4, beta-2 microglobulin and symptoms, lymphadenopathy did not independently predict AIDS (p=0.7).
Conclusion. Lymphadenopathy measured in two ways predicts future development of clinical illness or AIDS only weakly in HIV infection.

A.584 DIAGNOSIS AND MORTALITY TRENDS IN AN OUTPATIENT AIDS CLINIC

Keyes, Craig; Kelly, J.; Marte, C.
Bellevue Hospital Center/Community Health Project NY,NY USA.

Objective: To review trends in diseases of diagnosis and death in a community based primary care AIDS clinic population as a basis for improved management.
Methods: All cases (169) of AIDS diagnosed from 1/1/86 to 1/1/89 in a primary care out-patient AIDS clinic were reviewed for index diagnosis, year of diagnosis, diagnosis of death and year of death.
Results: Trends in diseases of diagnosis and diseases of death over three years are as follows:

Disease of Diagnosis

	1986	1987	1988
PCP	21(41%)	21(40%)	19(40%)
KS	22(43%)	17(32%)	13(27%)
All Other	8(16%)	15(28%)	16(33%)

Disease of Death

	1986	1987	1988
PCP	8(36%)	4(11%)	0(0%)
KS	1(5%)	7(20%)	8(35%)
Unknown/ Wasting	2(9%)	10(29%)	10(37%)
All Other	11(50%)	14(40%)	9(33%)

Conclusion: With the advent of PCP prophylaxis and improved management, mortality from PCP has decreased while the incidence of PCP has not changed significantly in our clinic population. More aggressive PCP prophylaxis may reduce the incidence of PCP as an index diagnosis. Mortality from pulmonary KS has increased, although KS has been less frequently diagnosed overall in these patients. The increasing number of AIDS diagnoses based on other diseases suggests that one should be alert to subgroups who would benefit from earlier diagnosis and treatment. Of special concern are the increased deaths from unknown causes. Perhaps more aggressive work-up might have elicited a definite diagnosis amenable to treatment, e.g., extrapulmonary pneumocystis.

A.585

SEROLOGICAL TREND FOR 22 MEXICAN HOMOSEXUAL PATIENTS THAT ARE SINTOMATIC AND ASINTOMATIC SEROPOSITIVE

Morales C.*; Romero M.*; Delgadillo S.* and Dominguez J.*
*Centro Nacional de la Transfusión Sanguinea, México, D.F., Mexico

Objetive.
To determine the presence of HIV Ag and the absence of p24 for one full year in 22 patients that were positive asintomatic and sintomatic.
Methods. The study was done in 16 asintomatic patients, 3 in fase I, 2 in fase II, and 1 with ARC. A determination of ENV/CORE and detection of HIV Ag in serum was made to each and everyone of them.
Results. The ones on fase II showed absence of p24 and only one was positive for HIV Ag; the patient with ARC was negative for p24 and positive for HIV Ag and one of the asintomatic patients showed absence of p24 and HIV Ag negative the rest of the patients did not show presence of p24 non HIV Ag
From this group of patients 5 have died and only one with HIV Ag positive in serum manifested all fases of the illness while the other four were victims of fulminant neurological alterations
Conclusion.
Acording to these finding we can conclude that for the group of patients, the trending stablished turned out to be quite interesting since for those patients that go through all fases of the illness it is posible to detect HIV Ag and the loss of p24 at a certain stage while in those that presented neurologicial alterations the HIV Ag was never detected.

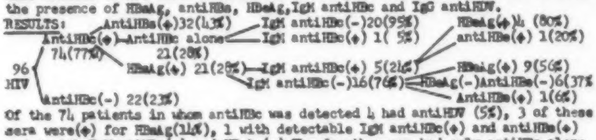
A.586

PREVALENCE OF HBV AND HDV MARKERS IN PATIENTS INFECTED WITH HIV IN BUENOS AIRES.

DRES. FAINBOIM H, BENETUCCI J, ASTARLOA L, GOMEZ N, CASTELLO T, SCHULKIN S, COMPAGNUCCI A, de SOUZA J, CORTI M and DIAZ LESTREM M. HOSPITAL F.J.MUÑIZ. BUENOS AIRES. ARGENTINA.

OBJETIVE: The purpose of this study is to evaluate the prevalence of HBV and HDV markers in a group of patients infected with HIV. METHODS: 96 patients (70 males-26 females between 15 and 53 years) were studied. 72 were IVDA, 17 homosexual, 6 partners of HIV(+)Patients and 1 hemophilic. The HIV seropositivity was detrmined by EIA and WB and they were all studied with HBV and HDV markers by EIA. AntiHBc titers were screened and on the positive patients it was detected the presence of HBsAg, antiHBs, HBeAg, IgM antiHBc and IgG antiHDV.

RESULTS:



Of the 74 patients in whom antiHBc was detected 4 had antiHDV (5%), 3 of these sera were (+) for HBsAg (14%), 1 with detectable IgM antiHBc(+) and antiHBe(+) and 2 with IgM antiHBc(-) and HBeAg(+). The fourth serum had only antiHBc alone (AntiHBcIgM-); 2 of these patients were IVDA, 1 homosexual and 1 bisexual IVDA. CONCLUSIONS: It's to be concluded that in the wholed population studied 77% had positive HBV markers and in the 22% HBsAg was found. The high prevalence of AntiHBc alone to be linked to parenteral addiction. The 5% of antiHDV that represents the 14% of the positive HBsAg sera, confirms the high rate of this virus in relationship to intravenous drug abusers in our country.

A.587

HAUTE PREVALENCE DE L'HTLV-1 ET FAIBLE PREVALENCE DU HIV CHEZ LES LEPREUX DE COTE D'IVOIRE.

A.Sangaré*, M.Verdier**, B.Sorro***, G.M.Gershy-Damet*, G.Léonard**, François Denis** et coll.*Institut Pasteur et ***INSP Abidjan Côte d'Ivoire ;**Virologie CHU Dupuytren, Limoges, France.

Objectif : Les études concernant lèpre et HIV ou HTLV-1 sont exceptionnelles. Il était intéressant d'étudier :

- la prévalence HIV et HTLV-1 chez les lépreux par rapport aux témoins
- l'influence des formes de lèpre et des zones géographiques sur la séropositivité

Matériel et méthodes : 584 sérums de lépreux et 812 sérums de population témoin ont été soumis à des tests de :

- dépistage HIV-1 et HIV-2 par ELISA Abbott recombinant HIV-1/HIV-2 EIA
  HTLV-1 par ELISA Abbott HTLV-1 EIA
- Confirmation HIV par Western blot Pasteur (Rapid Lav Blot 1 et 2)
  HTLV-1 par Western blot "maison" avec la souche HUT 102

Résultats :

	Lépreux	Témoins	Stat.
HIV	4,9 %	3,9%	NS
HTLV-1	14,4 %	1,9%	S (p 0.001)

En fonction des zones géographiques les prévalences chez les lépreux varient de 0,9 à 7,7% pour HIV et de 3,2 à 30,3 % pour HTLV-1. Il n'y a pas de différence significative de séropositivité pour un rétrovirus donné selon la forme de lèpre.
Conclusion : Les lépreux de cette étude menée en Côte d'Ivoire ne sont pas plus souvent infectés par le HIV-1 et/ou HIV-2 que les populations témoin.
Le virus HTLV-1 est retrouvé de façon significativement plus élevée chez les lépreux que chez les témoins (14,4% contre 1,9%). Il semble exister chez les lépreux des "clusters" HTLV-1.

A.588

EPIDEMIOLOGIC SURVEILLANCE OF HUMAN IMMUNODEFICIENCY VIRUS IN THE INDUSTRIAL CITY OF SIBERIA

Bela Anatolyevna Denisenko*, L. A. Bulwachter**, A. D. Malphanov,
*Head, Chair of Therapy; **Head, Chair of Dermatology, Institute for Advanced Medical Studies, Novokuznetsk, U.S.S.R.

Investigation of the epidemiology of human immmunodeficiency virus (HIV) is based on case detection in the Centers for Disease Control. As of December 1988, 45,807 cases of HIV have been tested in non-endemic areas. In the first stage of our investigation the inquiry-test data for all persons with clinically manifested immunodeficiency were used for detecting cases needed further clinical and immunological assays. A total of 1,078 of 45,807 reported cases with clinically manifested immunodeficiency were subjected to clinical and immunological testing. HIVs kill by damaging and ultimately destroying host's immune system, therefore cases with T-helper cell insufficiency were of our special concern. A randomized study for HIV identification was carried out in 40,7033 donors and in 3,473 cases, members of a high-risk group (homosexuals, drug addicts, intravenous drug abusers and women at risk), as well as in 523 foreigners and Soviet people who might have imported HIV from abroad. Immunoenzyme analyses were assayed in 37,867 cases by Soviet test-system and by MR-700 Microplate Reader, Zeidel Medizin Technik FRG. Our epidemiologic surveillance helped to detect one seropositive patient for HIV. This patient had been on a business trip abroad for about two years. Our data suggests that epidemiologic surveillance is recommended for AIDS identification in the non-endemic areas. All individuals at risk should be tested for direct HIV control.

A.589

AIDS: KNOWLEDGE AND ATTITUDES AMONG DIFFERENT ETHNIC GROUPS

Eskander, Gamal S.*; Jahan, M.* and Carter, R.*
*Meharry Medical College, Nashville, Tennessee, USA

AIDS is an international as well as a national public health problem. Since the identification of acquired immunodeficiency syndrome (AIDS) in 1981, the number of cases has steadily increased throughout the world. The World Health Organization estimated that the world total of AIDS cases will reach up to three million over the next five years. Despite the considerable national effort to promote AIDS education among the public, there are still some misconceptions regarding some alledged modes of transmission of AIDS.

To study the ethnic differences in knowledge, attitudes, and beliefs abount AIDS, we surveyed 161 U.S. residents from 31 different countries. An anonymous self-administered questionnaire was developed to compile this data.

The results of this survey suggest that AIDS-related knowledge is generally incomplete and there are still misconceptions about AIDS regardless of ethnicity or national origin. However, Americans and Europeans were more aware of some of the modes of contracting AIDS than people from Asia, the Middle East, or Africa. We conclude that some ethnic and nationa groups are more likely to have misconceptions about AIDS than others. Therefore, additional public educational programs and activities with special outreach programs for ethnic groups in the United States must be accomplished through methods that are culturally sensitive if they are to be effective.

A.590

AIDS ON LONG ISLAND.

Bruce D. Asins, M. Montgomery, S. Forlenza. Nassau County Medical Center, East Meadow, N.Y.

Objective. To describe the characteristics of the AIDS epidemic on suburban Long Island.

Methods. A retrospective review of epidemiologic and demographic data from the records of AIDS patients seen at Nassau County Medical Center (NCMC) during 1987 and 1988 was performed.

Results. Nassau County is the suburban area with the largest number of AIDS patients in the United States. NCMC is a NY State-designated AIDS Center operated by the county government. The AIDS Program includes a 25-bed inpatient unit and an outpatient clinic with >1500 visits annually. During 1987 and 1988, 229 CDC-confirmed AIDS patients were seen. Of these, 172 were men (75%) and 57 were women (25%). 57% were intravenous drug abusers (IVDAs), 28% were homosexual or bisexual males (HS/BS), 3.5% were from an endemic area, 3% were heterosexual contacts of HIV-infected persons (HET), and 4% had no identifiable risk. The others were children or acquired HIV through exposure to blood products. Among IVDAs (n=113), 55% are black and 45% are white. In 1988 specifically, 51% were white and 49% were black.

Conclusion. Risk factors for AIDS on suburban Long Island parallel those of New York City. At NCMC, blacks account for nearly half of all AIDS patients seen during the past two years, although they comprise only 7% of the total population in Nassau County. Women now account for 25% of cases. In contrast to New York City, the number of white IVDAs on Long Island is significantly larger, and equal to the number of black IVDAs in the region. These trends may reflect the patterns of AIDS demographics in suburban communities, especially those in close proximity to New York City and should be useful in planning for the care of the increasing numbers of HIV-infected patients expected in the future.

A.591

ELECTRONIC REPORTING SYSTEM FOR AIDS SURVEILLANCE IN CANADA

Nault, Penny; Elmslie, K. Federal Centre for AIDS,
Health Protection Branch, Ottawa, Ontario, Canada.

Objective: To describe the development of an electronic system for national reporting of AIDS surveillance data.
Methods: AIDS is a reportable condition in all provinces and territories in Canada. Through collaborative efforts between the provincial/territorial Ministries of Health and National Health and Welfare, a systematic method of reporting AIDS cases was established using a standardized case report form.
Results: The case report form was developed to collect demographic information, behavioural risk factors, clinical, and laboratory data. Completed forms are sent to the provincial/territorial Ministries of Health for evaluation and are then forwarded to the Federal Centre for AIDS. In 1986 the provinces/territories were introduced to an electronic bulletin board system, designed to facilitate data collection and dissemination. They were provided with custom computer software, and hardware where needed, to standardize the method of reporting cases electronically. Training workshops were provided to familiarize key groups with software and the process of transmitting data electronically.
Conclusions: This standardized method of reporting provides rapid collection of data and dissemination of reports. Effective communication between key groups plays an integral part in the success of this and other surveillance systems.

A.593

AN UPDATE ON HIV-SEROPREVALENCE STUDIES IN THE NETHERLANDS.

Lumey, L.H.;Houweling H.;Jager J.C.
Natl Inst Publ Hlth Env Hyg (RIVM), Bilthoven, the Netherlands.

Currently available data on HIV seroprevalence among selected groups in the Netherlands are inadequate to assess the spread of the epidemic among homosexual men, intravenous drug users or the population-at-large. So far, only volunteer studies have been conducted. Additional surveys are required: 1) to establish a base-line of infection levels in selected groups, 2) for public health management and policy, and 3) for modelling and prediction of the course of the epidemic.
Various options for conducting such surveys are discussed, and existing blood collections and hospital samples are identified. Anonymous testing of some of these blood samples is proposed to eliminate the self-selection bias which renders studies comprised of voluntary participants uninterpretable. Some legal and ethical objections have been raised that so far have prevented anonymous testing in the Netherlands. There is no general agreement yet that anonymous testing is needed to collect information that otherwise would not be available, and that such testing is justifiable if anonymity of the data is assured. In the meantime seroprevalence studies with informed consent will be considered in pre-selected institutions, to document wether compliance is high enough for valid inferences to be made from such studies.

A.594

PREVALENCE OF HIV-1 ANTIBODY AMONG GAY MEN IN THE U.K.: DIFFERENCES BETWEEN CLINIC ATTENDERS AND NON-ATTENDERS.

Davies, Peter*; Coxon, A.P.M.**; McManus, T.J.*** and Sutherland, S.****. Project SIGMA, *South Bank Polytechnic, London, U.K., **University of Wales, Cardiff, U.K., ***King's College Hospital, London, U.K., ****Dulwich PHLS, London, U.K.

Objective: To estimate the prevalence of HIV-1 antibody in the homosexually active male population of England and Wales and, bearing in mind that current estimates of prevalence and possible spread are based on those attending STD clinics, to estimate the differences between clinic attenders and non-attenders.
Methods: 525 gay and bisexual men in two centres in the U.K., London and South Wales, were recruited using a variety of methods and interviewed in a non-clinic setting. Blood samples were volunteered from 346 (66%) of these and tested for HIV-1 antibody using the Wellcome competitive assay. Positives were confirmed in the first instance with the Abbott recombinant assay.
Results: In London, 19 (9.4%) of the bloods tested positive to HIV-1 antibody. and in South Wales, 5 (3.4%). When allowance is made for verifiable test results from those who did not provide blood samples, these rates rise to 13.4% and 3.9% respectively. The proportion of positive results among those attending clinics was 13.4% in London and 7.4% in South Wales while the proportions among non-clinic attenders were 5.7% and 1.1% in the two sites. The higher rates among the clinic attenders are comparable with those obtained in clinic studies in comparable areas of the U.K.
Conclusions: Rates of seroprevalence of HIV-1 among gay and bisexual men based on bloods collected at clinics appear to be overestimates.

A.595

LA DEMANDE D'EXAMEN SEROLOGIQUE HIV CHEZ LE MEDECIN GENERALISTE

V. VAN CASTEREN, A. STROOBANT
INSTITUT D'HYGIENE ET D'EPIDEMIOLOGIE, BRUXELLES, BELGIQUE

Depuis le mois de mai 1988, la demande pour un test HIV a été introduite dans le progamme d'enregistrement de morbidité de 150 médecins généralistes sentinelles constituant un réseau représentatif des médecins généralistes de Belgique. L'objectif est d'évaluer dans quelle mesure le médecin généraliste est confronté avec le problème du SIDA, de suivre l'évolution de la demande au cours des années et de caractériser les situations dans lesquelles cette demande est formulée.
L'enregistrement est anonyme et comprend les données suivantes : âge et sexe, motif de la demande, comportement à risque éventuel, test HIV effectué ou non.
Les résultats des premiers mois de l'enregistrement montrent que moins d'une demande par mois et par médecin (0,8) est actuellement rencontrée. Près de 70% des femmes qui demandent un test ne présentent aucun facteur de risque alors que la proportion n'est que de 44% chez les hommes. Le taux de positivité des tests demandés est de l'ordre de 1,3%. Les résultats sont comparés avec ceux qui ont été enregistrés en France et en Suisse par des réseaux comparables.

A.596

A.597 EPIDEMIOLOGICAL, POLICY AND PLANNING ISSUES IN HIV DISEASE IN A BRITISH HEALTH REGION

Zwi, Anthony* and Kearns, William. North East Thames Regional Health Authority and *Department of Community Medicine, University College and Middlesex School of Medicine, London, England.

Objective To describe the epidemiological, policy and health services planning issues in relation to HIV disease within a region of the British National Health Service.
Methods Data on the regional epidemiology of HIV disease and the distribution of services were reviewed and the strategic policy and planning issues identified.
Results The North East Thames is the British health region second most affected by AIDS and has consistently contributed approximately 18% of all cases of AIDS diagnosed in the United Kingdom. Analyses of the geographic distribution of people with AIDS by where they receive medical care and where they live reveals that a few central London districts have attracted a disproportionate number of people with AIDS. These central London districts would be unable to continue to provide care for the vast majority of people with AIDS in the region. The Regional Health Authority has developed a policy for service development based upon the available epidemiological information. The strategy includes upgrading genitourinary medicine and problem drug services throughout the region, providing care as close as possible to where people live and establishing an appropriate balance between hospital, home and non-home non-hospital services. All districts have been funded to undertake educational, training, counselling and health promotion activities. Limitations within this approach to planning services are identified.
Conclusion The British National Health Service provides the potential for developing coordinated services of a high standard on a regional basis.

A.599 DECONTAMINATION OF AN HIV CONTAMINATED CPR MANIKIN:

Corless, Inge*, Lisker, A.*, Buckheit, R.U., Jr.*, Smiley, M.L.**, Langlois, A.J.***, Weinhold, K.***
*University of North Carolina-Chapel Hill; **Burroughs Wellcome, Research Triangle Park, N.C.; ***Duke University, Durham, N.C.

OBJECTIVE: Manikins are used widely for cardiopulmonary resuscitation (CPR) training. Simulating a "worst-case scenario", a manikin was contamined in different experiments with either cell-free or cell associated HIV-1. Recommended decontamination procedures were compromised by maintaining a wet surface for 10 or 5 sec rather than the recommended 30 sec. The experiment also addressed the relative contributions of chemical disinfection and the mechanical action of wiping.
METHOD: The manikin was contamined with either a virus saturated swab containing cell-free HIV-1 ($5x10^5$ infectious units/ml) or with a pipette containing cell-associated HIV-1 ($5x10^6$ chronically infected CEM cells/ml). The decontamination procedure consisted of 70% isopropyl alcohol sponge or spray or dry 4x4 sponge for 10 or 5 sec, drying time of 30 sec and 5 sec of wiping the surface. After each maneuver a sample from the manikin surface was obtained, cultured in AA5 or CEM cells and the presence of virus determined by reverse transcriptase assay and by quantitative p24 antigen detection (Elisa).
RESULTS: HIV-1 was detected after manikin contamination but not after disinfection with alcohol for 10 or 5 sec. HIV-1 was detected both after initial contamination and after wiping with a dry 4x4 sterile sponge.
CONCLUSIONS: Decontamination of an HIV-1 cell free or cell associated contaminated CPR manikin was achieved in 5 sec with either a 70% isopropyl alcohol sponge or spray, but not using only a dry 4x4 sponge demonstrating the importance of chemical disinfection.

A.601 RESISTANCE OF HUMAN IMMUNODEFICIENCY VIRUS TO DISINFECTANTS AND FIXATIVES

Peter Hanson*, D. Gor**, DJ Jeffries**, JV Collins*.
*Brompton, *St. Stephen's and **St. Mary's Hospitals, London.

Previous reports that HIV is susceptible to disinfectants are based on suspension tests. We tested 70% alcohol (IMS, Alcohols Ltd.; final concentration ethanol 63.8%, methanol 3.5%, water 26.5% v/v), acetone, 1% and 2% alkaline glutaraldehyde (Cidex, Surgikos Ltd) against HIV dried on a surface. The following inocula were dried in triplicate on to sterile coverslips and immersed in disinfectant: 1) Cell-free HIV in 10% serum at 10^4 TCID (TCID = reciprocal of the highest dilution of virus infecting tissue cultures within 7 days); 2) 10^4 HIV-infected T-lymphocytes; 3) Cell-free HIV (10^4 TCID) in neat serum. At timed intervals disinfectant was rinsed off with PBS-A. Coverslips were cultured for 21 days in RPMI with C8166 cells and examined for syncytia and HIV antigens; positive cultures were passaged into fresh cultures to confirm infectivity. Disinfectant-free and toxicity controled were performed.
Results: 70% alcohol failed to inactivate cell-free or cell-associated HIV within 20 minutes. Acetone, tested only against cell-associated inocula, failed to inactivate HIV within 40 minutes. 2% and 1% glutaraldehyde inactivated cell-free and cell-associated HIV within 2 minutes. In the presence of neat serum 2% glutaraldehyde remained effective but 1% failed to inactivate HIV within the 15 minutes tested. Conclusion: Acetone and 70% alcohol failed to kill HIV on surfaces within 40 and 20 minutes respectively; serum greatly reduced the efficacy of 1% glutaraldehyde.

A.598 OUTREACH TO IV DRUG USERS AND SEX PARTNERS: SATISFACTIONS AND DISSATISFACTIONS OF OUTREACH WORKERS

Stull, C.; Deren, S.; Graves, F.; Sufian, M.; Friedman, S.R. , Tross, S., et al.
Narcotic and Drug Research Inc., New York, New York, U.S.A.

Objective: Ex-addict workers are widely used for AIDS outreach to IVDUs and their sex partners. Our objective is to describe the characteristics of indigenous ex-addict outreach workers hired to provide AIDS prevention and education information to intravenous drug users and their sex partners in New York City, and to detail some of the satisfactions and dissatisfactions they encounter as employees.
Methods: A total of 66 outreach workers were employed by Narcotic and Drug Research Inc. during 1986-1988 to provide AIDS risk reduction information to IV drug users and their sex partners. Information was available through interviews with the 27 outreach workers currently employed by the agency and a review of agency records for all outreach workers.
Results: Of the 66 workers, approximately two-thirds (65%) were male and their ethnic composition was 58% Black, 39% Hispanic and 3% White. Most outreach workers were ex-addicts, recruited from various treatment modalities. Staff turnover at the end of one year of employment was 54%, i.e., of the 52 workers hired in 1986 and 1987, more than half were no longer employed by the organization within one year after their hiring date. Information on the satisfactions and dissatisfactions encountered by these employees is being collected and the data are being analyzed focusing on organizational issues (e.g., career paths available) and individual issues (e.g., burnout).
Conclusions: The relatively high turnover rate of these employees indicates that further study of the satisfactions and dissatisfactions experienced by these workers is needed, so that measures to address the dissatisfactions can be incorporated in employee policies.

A.600 RADIORESISTANCE OF HIV-1 IN A BONE ALLOGRAFT MODEL

Conway, Brian*; Tomford W.W**; Hirsch M.S.*; Schooley R.T.*; *Infectious Diseases Unit, **Department of Orthopaedic Surgery and Rehabilitative Medicine, Massachusetts General Hospital, Boston, MA, USA

Objective. To study the feasibility of inactivating HIV-1 in bone graft material by gamma irradiation.
Methods. Serial dilutions of HIV-1 (10^1-10^6 $TCID_{50}$/ml) were subjected to gamma irradiation under conditions simulating those within a bone allograft. Radiated and control specimens were cultured on H9 cells which were subsequently evaluated for cytopathic effect and p24 antigen production.
Results. High titers of virus (10^6 $TCID_{50}$/ml) were not inactivated by gamma irradiation up to 0.55 MRad. p24 antigen values (ng/ml) for lower titered radiated (R) and control (C) virus exposed to 0.4 MRad is shown:

			day 0	day 4	day 6	day 10
10	$TCID_{50}$/ml	(R/C)	0/0	0/0	0/0	0/7.6
10^2	"	"	0/0	0/0	0/.36	0/>500
10^3	"	"	0/0	0/.03	.31/3.6	362/>500
10^4	"	"	0/0	.11/.43	4.3/42.1	>500>500
10^5	"	"	0/0	2.0/4.5	4.3/>500	>500/>500

Cytopathic effect was observed in all cultures in which p24 antigen production was detected.
Conclusion. Doses of gamma irradiation previously recommended to inactivate many viruses including HIV-1 appear inadequate in this model. Higher doses or alternate methods of ensuring allograft sterilily with respect to HIV-1 may be required.

A.602 POTENTIAL FOR HIV TRANSMISSION VIA BLOOD GLUCOSE MONITORING DEVICES

Shalit, P.; Brennan, Cynthia; Murphy, V.; Hooton, T.
University of Washington, Harborview Medical Center, Seattle, Washington, USA

We are following a 43 year old HIV-positive insulin-dependent diabetic woman whose only known exposure to HIV was from vaginal intercourse with her HIV-positive bisexual husband. The woman indicated to us that since 1981 she has screened family members, friends, and relatives for diabetes by performing fingerstick glucose determinations on them. She would routinely use a single disposable lancet to draw blood from several individuals in rapid succession, after pricking herself, without wiping the lancet. Four family members who had shared a lancet with our patient during the past year have been screened and are HIV-negative.
We found that packaging material of the lancet's used by our patient contain no warning labels against sharing lancets. A local survey of 3 brands of lancets and 3 brands of lancet holders indicated that only 1 brand had labels warning about potential transmission of diseases with the devices. We also found no warning labels on some brands of insulin syringes. Diabetic equipment such as lancets and syringes represent a potential mode of transmission for HIV and other blood-borne pathogens. We speculate that the practice of sharing used lancets as demonstrated by our patient, a well-educated middle socio-economic class women, may be more common among diabetics than is generally recognized. Physicians and diabetic educators should educate their diabetic patients about the proper use of lancets and syringes and appropriate warning labels should be required on these products.

A.603

SIMILAR MAGNITUDE OF THE AIDS EPIDEMICS AMONG HOMOSEXUAL MEN IN COSTA RICA AND IN THE UNITED STATES

Mata, Leonardo*; Valadez, J.**.
*INISA, University of Costa Rica, San Pedro, Costa Rica;
**HIID, Harvard University, Cambridge, MA, U.S.A.

Objective. To compare the incidence of AIDS in homosexual and bisexual men in Costa Rica, with that in the United States, from the year the epidemics were first recognized ("year one").
Methods. "Year one" was 1981 for the U.S.A. and 1985 for Costa Rica. Cumulative incidence rates (per million) were calculated using the total number of cases among homo/bisexual men only, and the estimated yearly poulation of males 15 to 64 year, for each country. Rates were compared during eight years of epidemic: 1981-1988 for the United States and 1985-1992 for Costa Rica. Comparison used real numbers for the period 1981-1988, and estimated (power curve) numbers for the period 1989-1992 for Costa Rica.
Results. The cumulative incidence in homo/bisexual men in "year one" was 3.3 per million in the U.S. and 1.3 in Costa Rica. Differences between the two countries disappeared by "year three" of the epidemic. Thereafter, the ratio Costa Rica/U.S. incidence rates was close to 1.0 or actually 1.0.
Conclusion. Incidence rates show an epidemic in Costa Rican homo/bisexual men, of similar magnitude to that in the U.S., when comparison is made from the "year one" of the epidemic in each country.

A.605

MULTIPLE GROUP MODELS WITH HETEROGENEOUS MIXING FOR THE TRANSMISSION DYNAMICS OF HIV/AIDS

Castillo-Chavez, C*; Cooke, K.**; Huang, W.*** and Levin, S.A.*.
*Cornell University, Ithaca, NY, U.S., **Pomona College, Claremont, CA, U.S., ***Claremont Graduate School, Claremont, CA, U.S.

Objective. Specify ways of constructing multiple group models that take into consideration the social/sexual structure of a population; to present analytical results for single and multiple group models for the spread of HIV/AIDS; and to discuss the consequences of the "nonstandard" behavior observed in the multiple group models.
Methods. Mathematical Techniques are used in the analysis of these models (mathematical analysis and global bifurcation theory) and simulation techniques (numerical methods).
Results. We show that our single group models are robust and hence good building blocks for multiple group models (through the mixing theory of Blythe and Castillo-Chavez). We also show that, contrary to current thought, multiple group models can have multiple endemic equilibria.
Conclusion. These results show that the dynamics of standard epidemiological models is not as simple as previously thought. The consequences of these results in the 'real' world have to be assessed.

A.607

ADDITIONAL RISK FACTORS IN HIV POSITIVE PERSONS AS MONITORED BY A NATIONAL HIV NOTIFICATION SYSTEM

Hasseltvedt, Viggo, Lystad, A. and Nilsen, Ø.,
National Institute of Public Health, Oslo, Norway.

Objective. To study additional risk factors (e.g. sexual contact with person known to be HIV positive, sexual contact in a hyperendemic country, sexual contact with prostitutes), regarding persons notified as HIV positive where transmission category is known.
Method. The Department of Infectious Disease Control (DIDC), National Institute of Public Health, Oslo, Norway is in charge of the national surveillance of HIV infection and AIDS. HIV positive persons are reported to DIDC semi-anonymously.
Results. The various transmission categories, age groups, sex and other relevant categories are compared concerning data on additional risk factors. Up to 31/12/88 a total of 734 notifications of HIV positive persons were received at DIDC. Forty-four out of 121 persons with transmission category heterosexual practice were infected in hyperendemic countries and were also born in hyperendemic countries, 18 out of 121 were infected in hyperendemic countries, but were not born there, 6 women were infected by bisexual males. Other data will be available later.
Conclusion. More detailed data than just the transmission category is valuable in a national HIV notification system in order to improve the surveillance of the HIV epidemic.

A.604

HETEROSEXUAL CONTACT PATTERNS OF 429 PREGNANT NON-IV DRUG USING WOMEN IN THE SOUTH BRONX, NY, IN 1988

Drucker Ernest, Schoenbaum EE, Webber MP, Stern LS, Vermund SH, Gayle H*. Montefiore Medical Center, Bronx, NY; *CDC, Atlanta, GA; USA

OBJECTIVE: To quantify the probability of heterosexual exposure to HIV-I for non-IV drug using sexually active women in an area with high levels of HIV-I (especially among males age 25-34); and to explain known differences in seroprevalence by age, geography, and race/ethnicity among women of childbearing age.
METHOD: As part of an AIDS education and prevention project, we studied heterosexual contact patterns (HCP) of 429 non-IV drug using Black and Hispanic women receiving 1st trimester abortions at a clinic in the South Bronx (S.Bx). Structured interviews of these women between 4-7/88 elicited age, race/ethnicity (RACE), location of residence (RES), frequency of intercourse and drug use history of subjects (SUBJ) and their current sexual partners (CSP).
RESULTS:

	AGE OF WOMAN (N=429)				
	< 20	20-24	25-29	30-34	≥ 35
Age of CSP: Median (Range)	21(15-30)	26(19-55)	30(20-55)	34(23-60)	39(28-56)
Sex with CSP age 25-34	11.5%	46.0%	64.2%	69.3%	16.7%
Same RACE as CSP	89.5%	85.9%	92.5%	92.5%	83.9%

RES of CSP (zip code): same as SUBJ 41%; & adjacent 59.4%; S.Bx 70.2%; Bx 81.8%.
CONCLUSIONS: This study of HCP in the S.Bx indicates close concordance of the RACE and RES of non-IVDU sexually active women with their CSP, and an age-specific pattern of increased exposure, for 20-34 year old women, to high risk males. These patterns of heterosexual exposure are consistent with known age, RACE, and geographic differences in seroprevalence levels in the S.Bx, and suggest that HCP may play an important role in determining such distinctions.

A.606

Perinatal and Heterosexual Transmission Through HIV-Positive Women

Rehmet S., Staszewski S., Wegerich B.°, Kreuz W.°, Stille W., Zentrum der Inneren Medizin, ° Zentrum der Kinderheilkunde, Universitätsklinik Frankfurt

Since 1984, we have examined HIV-infected women and their partners in order to gain information on infectiosity, perinatal & heterosexual transmission rates, and possible relations between these factors. 44 Women examined in this period had born a total of 47 children since their HIV infection. 10 children are positive for HIV, 31 are negative for antibodies and direct virus identification; in 6 cases, HIV status is still questionable. A comparison between the group of women having infected their children and those not having transmitted the virus, shows no difference regarding immunological parameters, stage of HIV infection, tests for lues, CMV, and HBV. Of the women having infected their children, 60% were HIV stage 2a (Frankfurt classification); 40% were 2b with a median T4 cell count of 430 (27-964), the median ratio being 0.66 (0.03-0.92), duration of infection being 1-6 years. Out of 44 women, 33 women's partners are known and were tested for HIV: 16 are positive, 18 are negative for HIV. In no case had the man been infected by his HIV-positive female partner, also women having infected their children did not infect their partners.
Conclusion: Regarding immunological status, HIV stage at first examination, and tests for CMV, lues and HBV, there was no difference between mothers of infected, and mothers of non-infected children. The women having infected their children were immunologically good. This allows the conclusion that infection of children is also possible at an early stage of the mother's infection.

A.608

COMPARISON OF SURVIVAL EXPERIENCES OF NEW YORK AND CALIFORNIA MEDICAID AIDS PATIENTS

Markson, Leona*; Keyes, M.** and Turner, B.*
*Jefferson Medical College, Philadelphia, PA and **SysteMetrics, Washington, D.C.

Objective. To compare the survival experiences, hospital length of stay and costs of care of Medicaid AIDS patients in New York and California adjusting for severity level at the first recorded AIDS hospitalization.
Methods. Medicaid claims for AIDS patients in New York and California from 1983-1987 are linked in order to form longitudinal records of care for each patient. Patient characteristics including demographic factors, diagnoses and service utilization are summarized into monthly profiles. An AIDS staging system, developed using expert judgment, is applied to determine the severity level of the patients at selected intervals in the course of the disease. Life table and survival analysis techniques are used to study time from diagnosis within a distinct stage until death and to determine the relative risk of death for defined population groups.
Results. Survival curves and resource utilization patterns for AIDS patients classified by stage of disease are compared for patients from the two states and by year of diagnosis. Relative risks of death for patients by selected clinical complications are reported.
Conclusion. Distinct stages of the disease are useful to analyze survival experiences over time and to control for severity when comparing resource utilization patterns across different geographic areas. This is especially important in comparing New York and California AIDS patients due to major differences in the transmission mode of the infection.

A.609

PREDICTING IN-HOSPITAL MORTALITY FOR AIDS PATIENTS: A VALIDATED MODEL.

Steven A Grover*, N Gilmore**, J Palutz*, C Tsoukas,* L Coupal*, R Fakhry*. *Montreal General and **Royal Victoria Hospitals, McGill University, Montreal, PQ.

Estimating prognosis for a hospitalized AIDS patient is essential for optimal clinical management. We developed a prediction model for in-hospital mortality using admission data abstracted from 128 patient admissions to the Royal Victoria Hospital (RVH). This model was subsequently validated on 62 patient admissions to the Montreal General Hospital (MGH).

Using univariate analyses, stepwise logistic regression analyses, and clinical judgment, we identified independent predictors of in-hospital death including serum albumin (ALB) ($\beta = -1.32$), serum lactate dehydrogenase (LDH) ($\beta = +0.0047$), and leukocyte count (WBC) ($\beta = +0.27$) (all p's<0.05). High, medium, and low-risk groups for in-hospital mortality were defined where the probability of dying was set at 100%, <100% to >5%, and $\leq$5% respectively. Using the resulting RVH regression scores and 2x2 contingency table analysis, we determined the cutoff scores that corresponded to the above risk groups. The validity of the RVH model was then tested by classifying admissions at MGH. In-hospital mortality for the high, medium and low-risk groups was 100% (2/2), 42% (10/24) and 14% (5/36) respectively.

We conclude that routine admission laboratory tests associated with inanition (ALB), pneumocystis pneumonia (LDH), and other infections (WBC) help predict the outcome of hospitalizing patients with AIDS.

A.610

A.611

A.612

EVOLUTION OF THE CLINICAL AND LABORATORY PARAMETERS OF ONE PATIENT WITH HIV INFECTION IN THE FIRST YEAR AFTER HIS DOCUMENTED DATE OF SEROCONVERSION.

Georgopoulou, S.A.*; Ploumidis, G.M.*; Rouméliotou, A.N.**; Papadopoulos, A.I.*; Stergiou, G.D.*.
*1st IKA Hospital, Athens. **National Center of AIDS, Athens.

Objective: To present the pattern of changes in the clinical and laboratory findings observed during the first year after the date of seroconversion.
Method: A HIV-seronegative patient was admitted to our hospital suffering from a mononucleosis - like syndrome. On the 23rd day of his hospitalization and while he was free of any symptoms, he seroconverted. His clinical, haematological (Hct, Hb, White cell count and differential, platelets, ESR) and immunological (HIV Ag, Western Blot, lymphocyte subpopulation) profile was evaluated every 3 months for a period of 1 year.
Results: Since the time of seroconversion the patient remained symptomless. The size and number of his lymphnodes was reduced but they remained pathological (> 1 cm in diameter). His haematological values improved after the cessation of the clinical syndrome and remained within normal limits. The T4-lymphocyte count progressively increased to almost normal limits. The T8-lymphocyte count decreased significantly but without restoration to normal limits and the T4/T8 ratio improved. HIV-Ag remained negative and the full spectrum of antibodies appeared within the first trimester and remained positive since then.
Conclusions: The patient's transition from the acute AIDS stage and seroconversion (CDC Group I) directly to PGL (CDC Group III) was accompanied with an improvement of his clinical, haematological and immunological profile.

A.613

INFLUENCE OF HIV ON PRISON INMATE (PI) DIALYSIS (D) TRENDS

Glaser, Jordan*; Kaplan,J.*; Laio,P.*; Kleiner,M.*; Sudberg, L.*; McGinn,J.**.
*Richmond Memorial & Staten Island Hospitals, SI,NY; **Arthur Kill Correctional Facility (AKCF), SI, NY, USA.

Purpose: To assess the influence of HIV on PI D trends at AKCF.
Methods: Hospital and D unit record review.
Results: From 7/82 thru 12/88, 64 male NY State PIs underwent D, including 50 IVDUs and 14 non-IVDUs. Early (7/82-12/84) and later (1/85-12/88) D experiences for IVDUs were compared. No difference in: % of pts. who were IVDUs, # with serious infections requiring systemic Rx (6/21 vs 14/29), or mortality rate (2/21 vs 4/29). However: incarceration-D initiation interval decreased from 42 ± 35 mos (early on) to 11 ± 16 mos for IVDUs not on prior D, # of infectious episodes/pt. with serious infection increased from 1.5 ± 0.8 to 2.5 ± 1.2, # of deaths due to AIDS increased from 0/2 to 4/4, incarceration-death interval for IVDUs who died decreased from 42 ± 6 mos to 10 ± 8 mos, and # of IVDUs on CAPD increased from 1/21 to 11/29.

Eighty-one percent of IVDUs underwent HIV testing in 1987 and 1988. 12/13 (92%) were pos. Before 11/87, 6/39 IVDUs had transplants, but 0/11 were transplanted in 1988.
Conclusion: Most PIs on D are IVDUs who are usually HIV positive. They are experiencing more rapid decline in renal function, more infectious episodes and earlier mortality. More are undergoing CAPD and few, if any, are being transplanted.

A.614

HIV INFECTION IN PATIENTS ATTENDING A HOSPITAL BASED SEXUALLY TRANSMITTED DISEASES CLINIC

DeHovitz, J.; Freedman, P.; Bastien, A.; Morat, Y.
AIDS Prevention Center, SUNY - HSC @ Brooklyn, USA.

Objective. To determine HIV seroprevalence in patients who are attending STD clinic in a high prevalence area.
Methods. All patients attending an urban Hospital-based STD clinic were offered HIV-1 testing in a period between 8/88 and 12/88. Patients were given pretest, with posttest counseling scheduled two weeks following the initial visit. Risk information was collected by an interviewer using a structured questionnaire. HIV antibodies were determined by ELISA screening and confirmed by Western Blot.
Results. Data from 91 patients were analyzed and their seroprevalence was 19%. HIV Seroprevalence by risk category

Risk	Male% HIV +/total	%	Female HIV +/total	%
Gay/Bisexual	1/2	50	-/-	
IV Drug User	1/1	100	3/6	50
Sex partner	0/5	0	0/2	0
Prostitute (non-IVDU)	-/-		1/6	17
No risk	3/25	13	8/45	17
Total	**5/32**	**16**	**12/59**	**20**

Conclusion. The prevalence of HIV seropositivity in individuals attending an STD clinic is higher than previously reported. Even accounting for some misclassification of risk factors it appears that heterosexual transmission of HIV is a major route of infection in this STD population.

A.615

RISKS ASSOCIATED WITH ACQUIRING CHANCROID GENITAL ULCERATIVE DISEASE AND HIV INFECTION: A CASE CONTROL STUDY

McLaughlin, Margaret*; Wilkes,M.*; Blum, S.*; Hermoso, A.*; Schmid, G.***; *New York City Department of Health, NY, NY, USA; ***Centers for Disease Control, Atlanta, GA, USA.

Objective. To identify risks associated with acquiring chancroid and to evaluate the seroprevalence of human immunodeficiency virus (HIV) infection among men presenting with chancroid and gonorrhea to a New York City Department of Health sexually transmitted diseases clinic.
Methods. This case-control study was performed from 8/87 - 3/88 by interviewing all study participants. The case group consists of 66 men who had a chancroid ulcer, had positive cultures for H. ducreyi, and were without positive darkfield microscopies. The control group consists of 237 men who had urethritis and positive cultures for N. gonorrhoeae.
Results. On univariate analysis, cases were more likely than controls to be uncircumcised, to have exchanged a commodity for sex, and to have used crack. Homosexual behavior was noted in 4/66(6%) of cases, and 35/237(15%) of controls. Heterosexual cases were 6 times as likely as heterosexual controls to have a reactive RPR for syphilis. Antibodies for HIV were noted for 18% of cases and 17% of controls. Multivariate analysis, controlling for age, circumcision status, sexual behavior, ethnicity, exchange of drugs or money for sex, use of crack and IV drugs, RPR, and HIV antibody status confirmed that chancroid was predictive of a reactive RPR, commodity exchange, and a lack of circumcision.
Conclusions. In this study, chancroid was strongly associated with a reactive RPR, an exchange of drugs or money, and a lack of circumcision.

A.616

LOSS OF SEROLOGIC AND VIROLOGIC MARKERS OF HIV-1 IN ASYMPTOMATIC HIV-1 INFECTED HOMOSEXUAL MEN.

Homayoon Farzadegan*, S. Wolinsky**, J. Sninsky**, S. Kwok**, C. Rinaldo*, J. Phair*, R. Kaslow*, A. Saah*. From the *Multicenter AIDS Cohort Study (MACS), Bethesda, MD, & **Cetus Corporation, Emeryville, CA, USA.

OBJECTIVE: To follow virological and serological changes in 4 asymptomatic homosexual men who seroreverted from positive to negative for HIV-1 during the initial 2-2.5 yrs of evaluation. Peripheral blood mononuclear cells (PBMCs) of these participants showed detectable HIV-1 DNA by the polymerase chain reaction (PCR) method [Ann Intern Med 1988;108:785-90].
METHOD: Sera and PBMCs from these men were collected prospectively during 2-2.5 yrs of additional follow-up and tested for serological markers, PCR analysis and HIV-isolation. Phorbolester acetate (TPA), PHA, and U.V. treatment were used to activate HIV-1 expression.
RESULTS: Three men did not show detectable HIV-1 DNA by PCR (sk38/39 primer pair) and remained negative for serological markers and isolation of HIV-1 in the 2.5 yrs following seroreversion. CD_4 cells and CD_4/CD_8 ratic were normal. The fourth man became and remained seropositive during the last 2 yrs. HIV-1 DNA was detected in his PBMCs by PCR technique. His T-helper count declined and ratio was inverted. Attempts to activate expression of HIV-1 in PBMCs failed to show viral replication.
CONCLUSION: These data suggest that the three men with negative PCR and no serologic markers of HIV-1 may have cleared infection during the course of follow-up. Alternatively, PCR results may be limited by failure to detect of provirus remaining latent in a sequestered site.

A.617

HIV INFECTION IN LORRY DRIVERS AND THEIR ASSISTANTS IN EASTERN AFRICA

Carswell, John Wilson*; Namaara, W.**; Lloyd, G.***; Howells, J.***.
*Family Health International, Research Triangle Park, North Carolina, USA, **Ministry of Health, Entebbe, Uganda, Africa, ***Public Health Laboratory Services, Salisbury, Wiltshire, UK.

Objective. To quantify prevalence of HIV infection among long distance lorry drivers, and their assistants, in eastern Africa.
Methods. Sixty-eight lorry drivers and their assistants were tested for HIV while in Kampala, Uganda, in October 1986. Data were collected on travel history, prostitute contact and history of STD. Specimens were considered positive if they were repeatedly reactive to two separate ELISA assays and confirmed by Western blot and immunofluorescence.
Results. Twenty-four of the 68 (35.2%) had antibodies to HIV 1. Most had visited many of the 7 countries served by Mombasa in the previous 3 years. Both negative and positive individuals had extensive prostitute contact in the countries visited, and this was not significantly different between the two groups. Although negative by usual HIV tests, 7 persons had evidence of HIV, as determined by IgM and antigen testing. If these individuals are included, the rate of HIV infection is 45.5%.
Conclusion. High rates of HIV infection are seen in this group. Routine methods of HIV detection may not identify all infected individuals.

A.618

RISK OF INFECTION BY HUMAN IMMUNODEFICIENCY VIRUS IN HEALTH CARE WORKERS (HCW).

E Hernández, JM Gatell, T Puyuelo, JM Barrera, T Pumarola.
Occupational Health Service. Infec. Diseases Unit. Haemostasy Unit. Hospital Clínic. Barcelona. Spain.

Objective: To evaluate the risk of occupational transmission of HIV.
Methods: We have prospectively followed a cohort of 76 HCW who reported at least one episode of direct exposure to body fluids of HIV infected patients (presence of antibodies againts the HIV by at least two ELISA test and confirmed by Western Blot in 89.4 % of the cases) and who agree to participate.
Results: All 76 HCW denied risk factors for acquiring HIV infection in a confidential self administered questionnaire. All were seronegative by ELISA test, at the moment of the exposure to HIV infected body-fluids and none of them seroconverted after a median follow-up of 17 months (range 2 to 40 months).
Conclusion: Our results as well as the findings of the other authors indicate that HCW are at minimum risk for HIV transmission from occupational exposure.

A.619

AIDS SURVEILLANCE IN SICHUAN, CHINA

Dongyou, Yan; Chen, L; Lu, B; and Deng, P.
Health and Anti-Epidemic Centre of Sichuan Province, Chengdu, Sichuan Province 610031, People's Republic of China.

Objective. To monitor introduction of AIDS from the outside world.
Methods. We used antigen slides of T-cell line infected with HIV and indirect immunofluorescent antibody technique(IFA) for the detection of antibodies against HIV in sera of persons at high risk.
Results. So far, in our laboratory 1,327 sera collected from high risk groups of AIDS including Chinese workers coming back from Mideast and African countries, Chinese and foreign businessmen, students, visiting schoolars, and others coming in and going out of China between January 1987 and November 1988 were tested by IFA. No positive result was obtained.
Conclusion. To date, 19 AIDS cases have been found in China and among them no AIDS case of native Chinese who was infected by HIV through homosexual and/or heterosexual intercourse was discovered. Because of dramatic increase of prostitutes in Sichuan Province and of the incidences of sexual transmitted diseases, sooner or later, AIDS will be introduced in the native population in China and more recently a sera collected from a young service girl working at a hotel in Wuhan city in Hubei Province was found to be sero-positive by IFA and other tests. It is an unavoidable task for us to enhance AIDS surveillance in our Province and it is urgent to obtain support and collaboration from scientists and individuals engaging in AIDS in the world.

A.620

THE PRESENCE OF TUMOR NECROSIS FACTOR (TNF) IN SERUM AND IN LYMPHOCYTE CULTURES OF HIV-POSITIVE AND NEGATIVE HOMOSEXUAL SUBJECTS.

Buimovici-Klein, E., Lange, Michael, Mahan, D., Sonnabend, J.A., Grieco, M.H. and Cooper, L.Z.
St. Luke's-Roosevelt Hospital Center, Columbia University, New York, New York 10025

Objective. *Recent reports have described the presence of TNF in the sera of HIV-positive symptomatic (ARC,AIDS) individuals. We, therefore, attempted to correlate the presence of TNF in serum and in the supernatants of lymphocyte cultures with the presence of various viruses isolated from different body sites in HIV positive (H+ve) and HIV negative (H-ve) asymptomatic homosexual volunteers as well as AIDS patients and heterosexual controls.*
Method. *Sera and supernatants of lymphocyte cultures were obtained from 22 H+ve and 22 H-ve and were tested for presence of TNF by ELISA. Routine virus isolation were performed on samples taken from 5 body sites simultaneously (urine, semen, throat, rectum & blood) collected on same day as serum + LC. The sera of 32 patients with AIDS and 5 heterosexual controls were also examined for presence of TNF.*
Results. *As previously reported we found a high incidence of +ve virus isolation in both H+ve & H-ve volunteers. Thus virus culture was positive for CMV, or Enteroviruses, in 19 HIV+ve and 17 HIV -ve volunteers. TNF (20-200 pg/ml) was detected in the serum and LC supernatants of 20 HIV +ve and in all 17 HIV -ve persons with positive virus culture. Although the most frequently isolated virus was CMV, the highest TNF levels were correlated with isolation of enteroviruses. Of the AIDS patients 5 with severe (< 100 T4 cells/ml) and seven with stabilized forms of AIDS had none or very small amounts (< 10 pg/ml) of TNF in serum. The other 20 AIDS patients who had active opportunistic infections had serum TNF-levels ranging from 30 to 220 pg/ml.*
Conclusion. *The results suggest that the presence of TNF in sera or LC supernatants is related to the presence of viral infections or other opportunistic infections rather than to HIV infection per se.*

A.621

THE SEARCH FOR A COFACTOR IN AIDS-RELATED KAPOSI'S SARCOMA (KS): ASSESSMENT OF NITRITE INHALANT USE IN STUDIES OF HOMOSEXUAL MEN WITH AIDS.

Haverkos, Harry*; Drotman, D.P.**. *National Institute on Drug Abuse, Rockville, Maryland, USA; **Centers for Disease Control, Atlanta, Georgia, USA.

The epidemiology of KS in AIDS (the concentration among white homosexual men and the declining proportion of cases) suggests that HIV may not act alone as its cause. In transfusion-acquired AIDS from donors in whom KS subsequently developed, KS is rare, suggesting that a specific strain of HIV is not responsible. The use of nitrite inhalants and an "unknown" sexually transmitted agent have been proposed as KS cofactors. Objective. To review self-reported nitrite inhalant use, comparing AIDS-related KS and those with opportunistic infections. Methods. Studies (First authors: Darrow, Goedert, Haverkos, Mathur-Wagh, Osmond, Polk) have collected data about nitrite use from homosexual men with AIDS and compared use by disease outcome. Study design, wording of questionnaires regarding nitrite use (kindly provided by investigators), and published results were analyzed. Results. Three studies find a strong association between use of large quantities of nitrites and the development of KS, three do not. The differences in outcome may be due to differences in study methods, particularly sample size (range 19-150) and variation in measurement of nitrite use. Conclusions: The results of studies concerning nitrites and KS are inconclusive. Carefully designed epidemiologic and laboratory studies are needed to determine the cause(s) of KS in AIDS.

A.622

OCCURRENCE AND PROGNOSTIC VALUE OF AIDS-RELATED CLINICAL MANIFESTATIONS IN HIV-1 SEROPOSITIVE HOMOSEXUAL MEN

Kaslow, Richard A.*; Blackwelder W.*; Visscher B.+; Friedman H.*; Anderson, R.**; Fox R.++; MacDonell K.***; Kuo V.++ for the Multicenter AIDS Cohort Study (MACS). *Bethesda, +Los Angeles, **Pittsburgh, ++Baltimore, ***Chicago, USA

Objective. To use a clinical index to quantify early clinical progression of HIV-1 infection and determine the prognostic value of a single examination. Methods. A clinical index derived from early symptoms and signs of HIV-1 infection was used to score men based on data collected semiannually. Proportions of men with high scores were taken as prevalences of clinically significant immunodeficiency (CSID). $CD4^+$ cells were considered separately. Prognostic value of the index was based on life table probabilities of AIDS. Results. In 3.5 years of follow-up, prevalence of CSID rose from 4% to 34% in 1714 seropositives (SPs) and from 2% to 19% in 242 seroconverters (SCs). The initially healthy SPs and SCs had similarly rising prevalence (Table).

% of initially healthy who develop CSID alone and CSID + CD4 count < 400 at:

		Mos	0	6	12	18	24	30	36	42
[SPs], CSID	N=364	after	0	1	1	2	5	7	12	12
", CSID or CD4 <400		entry	0	6	6	8	16	18	25	29
[SCs], CSID	N=104	after	0	0	1	1	2	9	12	-
", CSID or CD4 <400		1st +	0	4	14	12	18	29	38	-

Overall, men with higher score progressed faster. High scores predicted progression earlier in men with low and later in men with high $CD4^+$ count. Conclusion. CSID rose 3-4% annually in healthy men with HIV-1 infection. The clinical index may be helpful in assessing progression of HIV-1 infection.

A.623

DETECTION AND QUANTIFICATION OF HIV-1 ANTIBODIES IN SEMEN

Hans Wolff*, A. Martinez*, J. Politch*, S. Saltzman **, K. Mayer** and D.J. Anderson*.
*Harvard Medical School and **Fenway Community Health Center, Boston, MA

OBJECTIVE. To measure levels of HIV-1 antibodies (Abs) of IgG, IgA and IgM subclasses in human seminal plasma (SP) from HIV seropositive men, and to compare titers to those in matched serum.
METHODS. Semen was obtained from 28 HIV-1 seropositive men and from 16 seronegative men. Corresponding serum samples were obtained from 11 men. HIV-1 Ab immunoglobulin subclass was determined in a DuPont ELISA using alkaline phosphatase-linked goat anti-human IgG, IgA or IgM Abs (Sigma). SP was screened at a 1/20 dilution for IgG Abs and at 1/4 dilutions for IgA and IgM Abs.
RESULTS. In 27 of 28 (96.4%) known seropositive men, anti-HIV-1 IgG Abs were detected in SP. None of the samples from seropositive men had detectable levels of IgA or IgM subclass anti-HIV-1 Abs. None of 16 known seronegative men had detectable levels of anti-HIV-1 Abs of any subclass in SP. In 11 seropositive men, anti-HIV-1 IgG Ab-titers were compared in serum and SP:

HIV-Ab	Titer Range	Median T.	Ser:SP Range	Median Ser:SP Ratio
Serum	20 - 327,680	20,480	8:1 - 2048:1	512:1
SP	0 - 640	40		

CONCLUSION. Detection of anti-HIV-1 Abs in SP was 96.4% sensitive and 100% specific when compared with serum values. However, anti-HIV-1 Ab titers were markedly lower in SP, and no secretory IgA was detected, consistent with transudation and not local production of antibody.

A.624

ELECTRON MICROSCOPIC (EM) ANALYSIS OF SEMEN FROM HIV SEROPOSITIVE MALES.

Pudney, Jeffrey; Wolff, H; and Anderson, D., Harvard Medical School, Boston, MA, USA.

Objective. To determine if the structural composition of semen changes following infection with HIV.
Methods. Transmission EM analysis of semen samples from HIV+ males (n=20).
Results. Normal semen contains spermatozoa plus a variable population of round cells composed of white blood cells (WBC) and immature germ cells released inadvertently and prematurely from the seminiferous epithelium. Based on the prevalence of their components, semen samples could be classified into 4 groups:

Group 1:	Essentially normal (6)
Group 2:	Increase of immature germ cell population; many abnormal (6)
Group 3:	Numerous abnormal late stage spermatids plus other immature germ cells; spermatozoa concentration decreased (4)
Group 4:	Few spermatozoa; samples consist of either: a) immature germ cells; b) anuclear cytoplasmic bodies; or c) WBC (4)

Conclusion. These data suggest a pattern of changes, with a decline in the concentration of spermatozoa but a concomitant increase in abundance of round cell types. Group 4 contained 3 samples obtained from males symptomatic for AIDS. These findings correlate with data from the examination of testes from 33 AIDS cadavers where regardless of age, duration of HIV infection, and cause of death, the testis was consistently azoospermic. Further work is in progress to understand the mechanism(s) that cause this azoospermia.

A.625

QUANTIFICATION OF CD4 LYMPHOCYTES, MACROPHAGES AND HIV ANTIGEN LEVELS IN VAGINAL SECRETIONS OF HIV+ WOMEN

Hill, Joseph A.*; Carpenter, C.C.J.**; Martinez, A.*; Politch, J.A.*; Mayer, K.** and Anderson, D.J.*.
*Harvard Medical School, Boston, MA, **Brown University, Providence, RI.

Objective. To quantitate HIV host cells (HHC) and HIV antigen in vaginal secretions (VS) of HIV seronegative women (n=5) and asymptomatic HIV+ women (n=7), women with CDC IV nonAIDS (n=5), and women with AIDS (n=6).
Methods. 30 VS were obtained from 18 HIV+ women and 20 VS from 5 low risk HIV^- women. Cell smears were analyzed by immunoperoxidase technique, using monoclonal antibodies to relevent leukocytes and HIV antigens. Cell free filtered supernatants were tested for HIV antigen by ELISA before and after culture.
Results. Potential HHC were detected in VS from HIV^- women only during menses and the proliferative phase. Levels were increased in asymptomatic women ($1.4x10^5 \pm 2.4x10^5$) and peaked in CDC IV women ($6.6x10^5 \pm 7x10^5$), as compared to HIV^- women ($3.3x10^4 \pm 3.3x10^4$). In AIDS, these cells declined to low levels ($1.2x10^4 \pm 2x10^4$), which may reflect HHC decline in the systemic circulation. AZT treatment did not affect HHC dynamics. HIV p24 antigen was not detected in either cell smears, fresh VS or culture supernatants.
Conclusion. Potential HHC are rare in the vagina of HIV^- women. Levels are increased in HIV+ women. Levels of HHC are highest in symptomatic HIV+ women prior to developing AIDS. The inability to detect HIV antigen in VS indicate that concentrations of infectious virus may be low in these fluids.

A.626

PETS AND HIV DISEASE: A SURVEY OF PROVIDERS' KNOWLEDGE AND ATTITUDES

Gorczyca, Kenneth*, Abrams, D.**, Carmack, B.***
*Pets Are Wonderful Support, San Francisco, California,USA,**San Francisco County Community Consortium,San Francisco, California,USA,***University of San Francisco, San Francisco, California,USA

Objective. To assess the knowledgebase of physicians expert in the care of individuals with HIV infection with regard to their understanding of zoonotic diseases and their attitudes regarding the interactions of their patients and their pets.
Methods. A 14 question survey was distributed to membership attending the San Francisco County Community Consortium meeting in January 1989. Members were aware that a presentation regarding pets and HIV disease would occur during the meeting. The questionnaires were returned prior to the presentation.
Results. Thirty-seven physicians completed the questionnaire. Only 19% of the respondents felt comfortable with their present knowledge on zoonotic disease. In selecting from a list of potential zoonoses that had been diagnosed in their patients with AIDS, 27 reported diagnosing toxoplasmosis; campylobacterosis (21); salmonellosis (19); ringworm (7); cat scratch disease (6); mites (4); psittacosis (3); pasteurellosis (2); brucellosis (1). Only 1 responded that they had diagnosed toxoplasmosis in a patient that they strongly suspected was transmitted from the patient's pet cat, with the other 26 having diagnosed toxoplasmosis responding negative. Forty-three percent believed however that cats pose a significant health threat to persons with AIDS/HIV infection. Birds were felt to pose a threat by 30 %; farm animals 22%; dogs 11%; all pets 3%. Sixteen percent of the respondents felt that no pets posed a significant health risk to their HIV infected patient populations. Ninety-seven percent suggested that companion animals are a major source of support and comfort for patients with HIV disease and 76 % felt that the benefits of pet ownership probably outweigh zoonotic risks. Sixty-two percent never recommend to their patients that they give away their pets after diagnosis. However, 68 % advised their patients with AIDS or HIV infection not to clean litter boxes; 38 % advised against adopting a stray kitten or puppy; 24 % not to feed pets raw meat and 22 % not to adopt a new pet. Of the responding physicians, 57 % currently owned a pet of their own, while 38 % have owned pets in the past.
Conclusion. The majority of physicians believed that the benefits of pet ownership for their patients with HIV disease outweighed the risks of potential zoonoses, especially if some precautions are taken.

A.627 A COMMUNITY-BASED HIV ASSESSMENT UNIT: HOW DOES IT WORK ?

Morgan, Aliyah, Davis I., Israni P., Ramis C.M., Norris B., Barnwell M, et al. - Woodhull Medical & Mental Health Center, Brooklyn, NY, USA

Objective. To describe how patients at high-risk for HIV infection are evaluated and treated by an interdisciplinary team of providers at a community-based HIV Assessment Unit.
Methods & Results. Woodhull Medical & Mental Health Center, a division of NYC Health and Hospitals Corporation, is a large municipal hospital serving an impoverished, medically underserved, black and latino community. Bushwick Family Health Center has been designated by Woodhull as the community-based facility for outreach, screening, evaluation and treatment of HIV-related diseases. The majority of high-risk patients are IV drug users and their sexual partners. An interdisciplinary team of providers, including clerks, administrators, nurses, physicians (*internists, pediatricians, psychiatrist*), and social workers, has been trained to meet the needs of this community. The roles of Team members and their interactions with patients will be discussed. An approach to the medical and psychosocial interventions provided to high-risk and HIV-infected patients will be presented. Emphasis will be placed on the medical protocols designed for a community-based setting. The process will be illustrated by following theoretical at-risk patients from initial referral to staff involvement and treatment.
Conclusion. A community-based program provides an ideal setting for an interdisciplinary team approach to the care of patients with HIV-related diseases or who are at high risk. This is particularly effective in an impoverished black and latino community.

A.628 EVALUATION OF COMPLIANCE RATE IN A CLINIC SERVING MINORITY AND LOW INCOME COMMUNITIES

Davis, Iris;Leibel, J.;Paroski, P.; Laqueur, P, et al.
Woodhull Medical and Mental Health Center, Brooklyn, NY, USA

Objective: To determine compliance rates for HIV-seropositive persons in a socioculturally sensitive clinic (SSC) setting from communities that are considered "traditionally noncompliant".
Method: Missed appointments rates were compared between the SSC and the ambulatory care network (ACN). The overall broken appointment rate was determined as a proportion of total appointments. Retrospective chart review explored factors contributing to missed appointments taking into account race, sex, age, risk behavior, treatment regimen and protocol. Patient specific missed and scheduled visits, and explanations of missed visits were documented.
Results: The average broken appointment rate in the SSC is 15%, and 40% in the ACN. When rescheduled appointments are considered the noncompliance rate falls below 10%. Factors contributing to missed appointments were conflict with work schedules, lack of child care, lack of adequate transportation, family illness, and hospitalization.
Conclusion: The overall compliance rate in the SSC is significantly higher than the ACN documenting (1) the importance of accounting for SSC variables in traditionally noncompliant com-munities (2) given the visit intensive regimens for HIV disease, clinic structure must be modified for communities with these variables, to increase participation in ambulatory care and research protocols (3) the social role of women as caretakers, regardless of their health status, is underestimated as a contributing factor to noncompliance in HIV disease treatment in these communities .

A.629 PREVALENCE OF ANTIBODIES AGAINST HIV-1 and HTLV-1 IN AFRICAN SERA SAMPLES COLLECTED DURING THE 1960's

Frenkl, Tatjana, McGhee, B., Lewinski, C., Longiaru, M., Nair, R.N.M.*, and Pottathil, R., et. al.
Roche Diagnostic Systems, Inc., Nutley, New Jersey, U.S.A., and *University of Michigan, Ann Arbor, Michigan, U.S.A.

Objective. To study the prevalence of HIV-1 and HTLV-1 infections during the 1960's in Ghana amoung the Akan, Ga-Adangbe, and Ewe tribes.
Methods. 404 archived sera samples from Ghana collected as early as 1960 were used in this study. Sera was screened for the presence of antibodies against HIV-1 and HTLV-1 using Roche recombinant HIV-1/HTLV-1 antigen combination screening EIA. This assay has been shown to have high specificity and sensitivity. Samples which showed reactivity in the HIV-1/HTLV-1 combination test were further evaluated for the presence of HIV-1 or HTLV-1 by using specific recombinant antigens.
Results. Thirty-five out of 404 (8.7%) samples showed reactivity with HIV-1-/HTLV-1 combination fusion proteins. Fourteen of the samples (3.5%) showed presence of antibodies against HIV-1 (gp120/gp 41). Fifteen out of 35 positives immuno-reacted only with HTLV-1 recombinant antigen (3.7%). Six samples had antibodies against both HIV-1 and HTLV-1 (1.5%).
Conclusion. HIV-1 and HTLV-1 infections may be more prevalent than estimated during the 1960's in Africa.

A.630 TRAINING THE HEALTH CARE PROFESSIONAL: THE AIDS REGIONAL EDUCATION AND TRAINING CENTERS PROGRAM OF THE HEALTH RESOURCES AND SERVICES ADMINISTRATION (HRSA).

Horner,June; Heffron,P; Martell,B; Moore,D; and Macher,A.
Division of Medicine, Bureau of Health Professions, HRSA,
United States Public Health Service, Rockville, Maryland, USA.

Objective. To establish regional AIDS education centers that will provide multidisciplinary training for health care professionals.
Methods. With a projected cumulative total of more than 300,000 AIDS cases by 1992, it is essential that health care providers be trained in the diagnosis, management and treatment of HIV-infected patients. The insufficient number of providers active in the care of AIDS patients presents a major gap in the health care delivery system. In recognition of this problem, the United States Congress appropriated funds to establish the AIDS Regional Education and Training Centers Program.
Results and Conclusions. To date, thirteen centers have been created. These regional education and training centers provide multidisciplinary HIV/AIDS training for health care personnel within the framework of the following three goals: 1) Training community primary care providers to incorporate strategies for HIV prevention into clinical priorities as well as to diagnose, manage, and counsel patients and their families; 2) Training individuals to serve as instructors in their local area; and 3) Educating health care professionals in providing sensitive and integrated care of AIDS patients through the improvement of their understanding of the complexities of the disease.

A.631 INCREASED SUSCEPTIBILITY OF UNSTIMULATED PERIPHERAL BLOOD MONONUCLEAR CELLS (PBMC) AND CD8+ CELL-DEPLETED PBMC TO IN VITRO INFECTION WITH HIV AFTER INGESTION OF 2 TO 4 BEERS.

Bagasra, Omar*; Lischner, HW**; Kajdacsy-Balla, A***. *Univ. of Med. & Dent. of New Jersey, Camden, NJ; **Temple Univ. & St. Christopher's Hosp. for Children, Philadelphia, PA; ***Univ. of Oklahoma, Oklahoma City, OK, USA.

Objective. To determine the duration of the previously described effects of acute ethanol ingestion on HIV infection of PBMC in vitro (FASEB J 2:A831, 1988) and the influence of removal of CD8+ cells on these phenomena.
Methods. PBMC isolated from 3 healthy non-alcoholic vounteers before and almost daily after consumption of 0.7-1.3 (mean 1.1) liters of beer, and PBMC depleted of CD8+ cells by panning 2 times on anti-CD8, were cultured for 28 days (12 wells each) with HIV-1 (HTLV-IIIB) and fresh IL-2 (6 U/ml) every 3 days. HIV replication was estimated by: a) counting the syncytia appearing after overnight incubation with SUP-T_1 cells, and b) assay of HIV-p24 by antigen capture enzyme immunoassay in 48 hr supernates (depleted PBMC only).
Results. HIV infection of PBMC was detectable only if CD8+ cells were removed in vitro or if the PBMC were obtained ½ to 1½ days after ethanol ingestion. The latter was associated with a 3-fold rise in syncytium formation when CD8+ cell-depleted PBMC were used. Means of 4 syncytia per well were found before beer consumption, 12 per well the morning after, and 6, 5 and 2 per well 1½, 2½ and 4½ days, respectively, after ingestion of beer.
Conclusions. CD8+ cells prevent HIV infection of normal unstimulated PBMC. Prior ingestion of beer increased the susceptiblity of PBMC to HIV infection in vitro for at least 1½ days. Alcohol-associated enhancement of HIV replication occurred after removal of CD8+ cells and thus was not due entirely to the loss of CD8+ cell function previously ascribed to alcohol ingestion.

A.632 THE OPPORTUNISTS IN HUMAN AIDS (HAIDS) ARE ZOONOTIC.

Torres-Anjel, Manuel J.*, Rueda, Robert H.**
* Univ. of MO Columbia, USA **; R. Montgomery HS, Bethesda, MD USA.

Objective. To explore animal diseases and animal products with respect to HAIDS.
Materials. The opportunists associated to HAIDS were searched in the AIDSLINE database with GRATEFUL MED™ software and scrutinized vis-a-vis the concept of zoonoses [1]. The number of publications devcted to each were recorded (in parentheses) as an estimate of their relative importance. Most of them, as indicated with an asterisk (*), are also CNS infective .
Results. Cytomegaloviruses (694) and influenza (15) viruses are well spread in the animal kingdom. *Pneumocystis carinii* (630) is a parasite of rodents, Toxoplasmosis (212*) autochthonous to cats and Cryptosporidiosis (96*)to several other species. Cryptococcosis (141*), histoplasmosis (50*) and coccidioidomycosis (15*) are saprozoonoses and candidiasis (160*) is common in animals. The mycobacterioses (135*), including tuberculosis, are infections of, or shared with, animals. Salmonellosis (30), campylobacteriosis (10) and listeriosis (10*) are, frequently, although not always or only, associated to foods of animal origin. Cat scratch disease (3) and lyme disease (3) are also involved in HAIDS.
Conclusion. Opportunists, the major causes of death in HAIDS, are zoonoses [1] and thus conceivably acquirable from animals and/or animal products. The epidemiology of this approach needs urgent evaluation. Used in conjunction with the animal AIDS models [simian (SAIDS), feline (FAIDS), bovine (BAIDS), equine (EAIDS) rabbit (RAIDS), murine (MAIDS), etc], they could be useful in the pathobiological modelling of HAIDS. The HIVs themselves are infective both to closely related (primates) as well as to far removed (rabbit) animal species, share common ancestors with the animal lentiviruses and thus are zoonotic.

1. Acha & Szyfres, 1987, PAHO/WHO, Scient. Publ No. 503.

A.633

EPIDEMIOLOGIC STUDY OF CHILDREN OF HIV INFECTED WOMEN IN PRIMARY HEALTH CARE.

Perez-Alvarez, Teresa; Merodio, C.; Babin, F.; Ortiz, C.; Colomo, C.; Saetre, J.

C.P.S. Centro. Madrid Council. Spain.

OBJECTIVE: To show social and sanitary variables influencing HIV positive children and HIV negative children, of HIV infected women before pregnancy.

METHODS: Analytic and descriptive study of 40 social and sanitary parameters obtained of cases studied in the pediatric unit between january 87 and january 89.

RESULTS: Characteristics of studied children related to HIV infection.

Positive children:	Not followed-up	changed to negative	stage
< 15 months	0 (0%)	2 (20%)	P0=8 (80%)
> 15 months	2 (16,6%)	6 (50%)	P1A=3(25%) P2A=1(8,3%)

Control group: All the cases continued beeing seronegative without lost cases in follow-up.

No significant differences were found between the two groups except for the relation between brest-feeding and positive serostatus of the child.

CONCLUSIONS: The frequency of seroconvertion to HIV of brest-fed children is lower than the one found in not brest-fed children (p<0.001).

More studies of individual factors in perinatal transmission are needed.

The evolution of children of more than 15 months was satisfactory. That could be related to the preventive character of our children's AIDS program, that make possible early diagnosis of asympthomatic children. Other series published refer to children consulting hospitals because they have a pathologic process.

No one of the seropositive children that become negative turned to be seropositive again.

A.634

HIV-2 INFECTION IN SARDINIA

Aldo Pintus, S.Piras, L.Contu, F.Pitzus
Istituto di Clinica Medica, Università di Cagliari, Italy.

Objective: HIV-2 infection has been found only in few cases in Italy but no data are,by now,known about the presence or absence of this virus in Sardinia were there are about 15.000 drug abusers(DA) on 1.500.000 inhabitants and 1500 beta-thalassemic(BT)patients.Considering that AIDS cases are rapidly increasing expecially among drug abusers and the high frequency of transfusion in BT we have made the present work to know if this second "AIDS virus" is or is not present in our island.
Methods: Sera from 288 individuals(94 DA,58 BT,17 hemofiliacs,36 partners of HIV-1 infected people,9 young men from Senegal and 33 subjects without any known risk factor)have been submitted to ELISA,WB and RIPA for HIV-1 and HIV-2.
Results:On 69 sera HIV-1 positive 58(84%)were also positive for HIV-2.On the 219 anti HIV-1 negative sera 5(2.3%) showed a strong reaction against HIV-2 (ELISA and WB).Four sera belonged to DA and 1 was from a young Senegalese man.Only few very faint cross-reactivity against HIV-1 epitopes were found in 1 HIV-2 positive serum while a cross-reactivity(anti-core) anti HIV-2 was present in the majority of anti HIV-1 positive sera.
Conclusion: The above data demonstrate that also in Sardinia there is a presence of HIV-2 and it is significant that 4 of the 5 cases are from DA and 1 is from Africa.This suggest the importance of a wider screening for this virus among DA and people in relationships with Africans.The strong cross-reactivity HIV-1 versus HIV-2 needs of more specific tests to better discriminate between the two viruses.

A.635

TRANSMISSION HETEROSEXUELLE DU VIH: SURVEILLANCE HOSPITALIERE EN AQUITAINE, FRANCE, 1985-88

Poumerol, G.*; Chasterie, A.*; Morlat, Philippe**; Lacoste, D.**; Dupon, M.**; et le Groupe d'Epidémiologie Clinique du SIDA en Aquitaine (G.E.C.S.A.)**
*Département d'Informatique Médicale, Université de Bordeaux II, Bordeaux, France
**Centre Hospitalier Régional Universitaire de Bordeaux (CHRU), Bordeaux, France;

Objectif. Un système de surveillance épidémiologique des sujets infectés par le VIH a été mis en place au CHRU de Bordeaux. Il permet d' étudier les différents modes de transmission de l'infection.
Méthode: Les services hospitaliers participants incluent leurs patients séropositifs depuis 1985. A chaque consultation, les données sont recueillies sur un questionnaire standardisé puis sont rendues anonymes et informatisées. Les caractéristiques épidémiologiques suivantes sont enregistrées pour chaque patient: âge, sexe, groupe ou comportement à risque pour le patient et son (ses) partenaire(s) sexuel(s), motif de la demande de sérologie.
Résultats. Au 10 Octobre 1988, 648 adultes séropositifs ont été inclus (sexe ratio Homme/ Femme H/F= 3:1). Parmi ces sujets, 415 (64%) sont hétérosexuels (H/F= 1,6:1), dont 58 (14%) ont comme seul facteur de risque identifié un contact avec un (des) partenaire(s) à risque ou séropositif(s). Les femmes prédominent dans ce sous groupe (H/F= 1:3). De 1985 à 1988 on observe une augmentation régulière de la part relative de la transmission hétérosexuelle parmi l'ensemble des sujets inclus (4 % à 11%). Cette tendance est parallèle à l'augmentation de la demande de sérologie chez les partenaires de sujets à risque ou infectés. Parmi les 41 femmes infectées par contamination hétérosexuelle, le (les) partenaire(s) a (ont) été identifiés comme toxicomanes IV dans 61% des cas, 80% de ces partenaires toxicomanes IV étant connus comme séropositifs. Chez les 18 hommes infectés par contamination hétérosexuelle, les rapports sexuels avec une (des) prostituée (s) est (sont) retrouvés dans 7 cas et avec des toxicomanes dans 4 cas.
Conclusions. En Aquitaine, la population hétérosexuelle contaminée par voie sexuelle se caractérise par une prédominance de femmes infectées au contact de toxicomanes. Ce mode de transmission pourrait jouer un rôle prépondérant dans la diffusion de l'infection à la population générale.

A.636

CARACTERISTIQUES EPIDEMIOLOGIQUES DES NOUVEAUX SEROPOSITIFS VIH DANS LE CENTRE-OUEST DE LA FRANCE : EVALUATION DE L'INCIDENCE ET DES COMPORTEMENTS.

Marchand S.*, Choutet P.* et les membres du GERICCO**
* CHRU Bretonneau, 37044 TOURS (France)
** Groupe d'étude et de Recherche en Infectiologie clinique du centre-ouest.

Objectif : avoir des marqueurs d'évaluation de la compréhension et de l'application des mesures de prévention véhiculées par les campagnes d'information ; en surveiller l'évolution au cours du temps dans le but de mieux cibler les actions.
Méthodes : les marqueurs choisis ont été : 1° la mesure de l'incidence des nouveaux cas de séropositivité ; 2° l'enregistrement simultané de paramètres comportementaux. Il s'agit d'un enregistrement permanent à partir des laboratoires effectuant les sérologies en Western Blot et en collaboration avec les médecins prescripteurs.
Résultats : une enquête réalisée en région centre-ouest du 1 juin au 31 août 1988 à partir de 6 centres hospitaliers universitaires a analysé 68 dossiers de sujets dépistés depuis le 1 janvier 1988. Soixante-douze pour cent de cette population appartenait aux deux groupes à risque : homosexuels-bisexuels (44%) et toxicomanes IV (28%). Seulement 30% des cas avaient fait d'eux-mêmes la demande de sérologie, soit du fait de leur appartenance à un groupe à risque, soit en raison de l'apparition des symptômes. Dans ces deux groupes, le tiers des sujets n'avait pas connaissance de leur risque de contamination. Le tiers des sujets homo-bisexuels et la moitié des toxicomanes avaient préféré ignorer leur statut sérologique. Ces résultats ont motivé la mise en place à partir du 1 janvier 1989 d'un enregistrement permanent dont les premiers résultats feront aussi l'objet de la publication.
Conclusion : l'espoir d'enrayer l'épidémie est actuellement fondé sur la prise de responsabilité des sujets contaminés vis-à-vis de la dissémination du virus et sur une connaissance des situations à risque par ceux qui peuvent être exposés.

A.637

PROFILE OF HIV-INFECTED PATIENTS AT SAN FRANCISCO GENERAL HOSPITAL OUTPATIENT CLINICS.

Wong, Roberta J, Gumbley-Smith D, Volberding P. Department of Medicine, San Francisco General Hospital, San Francisco, California USA.

Objective: To document characteristics of patients who receive medical care at SFGH AIDS adult outpatient clinics.
Methods: Of 2000 patients receiving primary care at SFGH AIDS clinics, 100 charts were randomly selected from a computer list of visits from December 8 to 13, 1988.
Results: There were 92 males and 8 females, average age of 38 (median=38, range 25 to 58). There were 79 Caucasian, 10 Black, 7 Latino, 1 Asian, and 1 Native American. Breakdown by initial diagnosis and average time from diagnosis to present was 25 PCP cases (13mos), 11 KS(24.5mos), 39 ARC(15mos), 8 LAN(24.5mos), 5 HIV+ (4mos), 5 at risk(4mos), 6 other OI(16mos) and 1 dementia (2mos). 30 have a history of recreational drug use, with 15 still actively using. Fifty-five have used zidovudine and 33 have used aerosol pentamidine with 24 patients on both agents. There were 28 on zidovudine and acyclovir. Chronic drug use ranged from 0 to 11,with 44 on 3 to 5 drugs and 8 patients each on either 2 or 6 drugs. An average of 2.2 allergies were reported(median=2, range 1 to 8) in 25 patients, while 35 had NKA and 40 were unknown.
Conclusion: The HIV-infected population at SFGH is unlike the US distribution of cases due to the greater incidence of Caucasian homosexual individuals. Patient profiles from other areas of the country are currently not available for comparison. Future studies need to determine if there are regional differences in standards of treatment affecting morbidity and mortality. Improved therapeutic monitoring may contribute to a better understanding of HIV disease.

A.638

A COMMUNITY-BASED MODEL FOR PRIMARY CARE AT AN HIV ANTIBODY ALTERNATE TEST SITE

Howard, John*; Mahon, R.**; Duynstee, S.**; Walker, M.**; and Brooks, S.
*University of California, Irvine, CA, USA, **Edelman Health Center, Los Angeles, CA, USA.

Objective. We set up a community-based clinic in Los Angeles at a HIV antibody alternate test site for the medical and psychological evaluation of antibody-positive testees.
Methods. Health history, physical exam, laboratory tests and psychological assessment were obtained on 1200 subjects from the alternate test site over a period of three years (1/86 to 12/88).
Results. Subjects were white (75%) and male (99%) with 15% Hispanic and 7% black. Seven hundred eighty nine were asymptomatic, while 211 exhibited only mild fatigue and low-grade fever. Physical exam showed 54% had swollen lymph nodes, 5% had onychomycosis, and 4% had thrush. Despite normal white blood cell counts, the mean number of T4 lymphocytes was 408 cells/mm^3. Psychological assessment revealed 43% with symptoms of depression or situational anxiety.
Conclusion. Our study suggests that medical and psychological evaluation should be provided at HIV antibody test sites. Evaluation of HIV antibody-positive persons in conjunction with an alternate test site facilitates the early detection and treatment of HIV-related medical and psychological problems.

A.639

HEALTH WORKERS FOR THE AIDS EPIDEMIC IN THE USA: WHAT WE KNOW AND WHAT WE NEED TO KNOW

Hall, Thomas*; Dunham, N.**; Wittenberg, E.*; Knickman,J.**.
*Univ. of Calif./San Francisco, USA, **New York University, New York, USA

Objective. To define available and needed information regarding health worker training and deployment to cope with AIDS. Methods. The literature through 1988 was reviewed and 29 persons knowledgeable about different aspects of staff training and utilization were interviewed. Results. More than 100 relevant citations were found though only about 25 offered substantive findings. No estimates were found as to likely staffing or training requirements except in the case of internists. Most of 18 reported knowledge and attitude studies found major knowledge gaps and 20 to 40% of the respondents had substantial fears of and/or aversion to caring for HIV-infected persons. Infection control requires much more attention. Information on other than physicians is very limited and no studies were found that explicitly examined skills and practices. The six reviewed descriptions and evaluations of training programs reported improvements in knowledge levels though evaluations have generally been very limited and have not explored the relationships between knowledge, attitudes, and behaviors. Conclusions. Reported research on training needs and methods is still very limited in scope, rigor and comparability. Although experience should provide an adequate basis for setting near-term priorities, research should be intensified, especially as regards: 1) the development of cost-effective methods for training, particularly as it relates to skill development and attitude change; 2) estimating future training requirements and costs; and 3) documenting preferred methods for improving personnel recruitment and retention in HIV programs.

Clinical Aspects of AIDS

Le VIH chez les enfants
HIV in Children

M.B.O.1

HIV-RELATED SYMPTOMS IN CHILDREN BORN TO HIV POSITIVE MOTHERS - RESULTS FROM THE EUROPEAN COLLABORATIVE STUDY

Catherine Peckham for the European Collaborative Study. Collaborating centres include: Padua, Berlin, Edinburgh, Madrid, Valencia, Amsterdam, Stockholm and Genoa.

Objective To describe the natural history of HIV infection in children. Method In the European Collaborative study of children born to HIV positive mothers, children are being followed with three -monthly clinical and laboratory testing by standard protocol. Only children who were 18 months or older at their last visit were included in this part of the analysis. AIDS/ARC is defined as previously reported. Significant HIV related symptoms are defined as two or more of the following: persistent generalised lymphadenopathy, persistent hepatomegaly, persistent splenomegaly, chronic or recurrent diarrhoea, acquired microcephaly, growth retardation, regression of developmental milestones, persistent fever of unknown origin, viral or bacterial infections. Results Of the 315 children enrolled by 20 January 1989, 13 have developed AIDS/ARC (5 of whom have died), and a further 27 had symptoms suggestive of HIV infection. Of the 118 children followed for more than 18 months, 27 were presumed to be infected. Of these, 10 were diagnosed as AIDS/ARC, 7 had symptoms suggestive of HIV infection and 10 were well when last seen. Of the 91 presumed not infected children over 18 months, 1 showed symptoms suggestive of HIV infection. Time to onset of first symptoms will be presented. As yet no child has developed AIDS/ARC after the age of 9 months. The most common presentations of symptoms and immunological findings will be described.

M.B.O.2

NATURAL HISTORY OF INFANTS BORN TO HIV POSITIVE WOMEN

Willoughby, Anne*, Mendez, H.**, Goedert, J.*, Berthaud, M.**, Moroso G.**, Sunderland, A**, et. al **SUNY-HSC at Brooklyn, N.Y. and * N.I.H. Bethesda, Maryland, U.S.A.

OBJECTIVE: To determine the rate of "perinatal" transmission and to describe the natural history of children born to HIV SP mothers. METHODS: Drug Using (DU), Haitian, and referred women identified in prenatal clinics, and their offspring, are followed for 4 yrs; clinical, lab and immunological data are collected at regular intervals. RESULTS: From 1/86 to 10/88, 160 women delivered, 74 (46%) were SP. Of 70 SP live births, 8 (9%) were lost to follow up. Of 30 children ≥15 mos of age, 10 (33%) were HIV infected. Seven of these 10 had AIDS,(3 are dead) 2 had P_2A class of HIV infection and 1 was asymptomatic. The initial clinical manifestations included: Hepatosplenomegaly (HS) at 1 to 5 mos in 6, Hepatomegaly (H), at 3 and 6 mos in 2, and neurological abnormalities (NA) by 1 year in 1 infant. Persistent lymphadenopathy (PL) was present in 7/10 by one year of age. In contrast, of 20 infants that seroreverted (SR) (mean age: 22 mos, range 15-31 mos) 2 had failure to thrive and 2 had microcephaly (all born to DU mothers). None had H, HS or PL. Immunoglobulins were high in infected infants while SR had normal values. Percent T_4 Cells and T_4/T_8 were lower in the infected infants, however, these values did not predict infection early in life. All infants that SR have remained seronegative. CONCLUSION: One third of infants born to SP mothers were infected and the majority had infection detected clinically by 1 year of age.

M.B.O.3

PROSPECTIVE STUDY OF INFANTS BORN TO MOTHERS SEROPOSITIVE TO HIV1. FRENCH HIV IN NEWBORN STUDY GROUP. (Paris, Nice, Toulouse, Bordeaux).

S. Blanche, F. Veber, MJ. Mayaux, C. Rouzioux, AM. Dulidge, ML. Moscato, C. Griscelli

This cohort include now more than 400 mother-child couples. The last analysis concern 308 children. Of the 117 infants analyzed at 18 months of age, 27 % showed certain HIV infection, 65 % were symptom free and have become seronegative whilst 8 % were seronegative but presented discrete symptoms possibly related to an HIV infection. The infants infected by HIV were divided up among different groups as regards their clinical status at 18 months of age : 2 infants were symptom-free, 11 had non-specific general symptoms of moderate intensity and 19 suffered from a severe evolutive form of HIV infection of whom 6 have died. At birth, the infants infected by the HIV virus did not differ from the rest in terms of weight, height, head circumference and frequency of evident malformations. Nonetheless, a rise in the rate of IgM in the serum was found (78 ± 81 mg/dL against 38 ± 39 mg/dL ; $p < 0.03$) and a drop in the number of CD4 blood lymphocytes (2054 ± 1221 mm^{-3} against 2901 ± 1195 mm^{-3} ; $p < 0.006$) As expected, infants born to drug-addicted mothers, whatever their viral status were smaller, lighter and had a smaller head circumference. The percentage of infants infected at 18 months was not influenced by the mode of contamination of the mother nor by the mode of delivery. The difference observed between infants born to symptomatic mothers and infants born to symptom-free mothers was not significant. It would appear that breast-feeding led to a higher risk of infection in the child (83 % against 25 % $p < 0.01$) although number of breast-fed infants in this study was very low. The risk was the same for infants living with their mother as for those raised in an institution or in a foster family.

M.B.O.4

PROSPECTIVE EVALUATION OF IMMUNE FUNCTION IN INFANTS BORN TO HIV-SEROPOSITIVE MOTHERS

Rogers, Martha; The NYC Perinatal HIV Transmission Collaborative Study Group. CDC, Atlanta, GA; NYC Dept. of Health, NY, USA.

Objective To evaluate immune function in infants of mothers at risk for HIV. Methods CD4, CD8, and Ig are measured every 2-6 mos from birth in infants of mothers at risk for HIV. Infected infants (CDC-defined) were compared with those born HIV+ who remained well and seroreverted and infants born HIV-. Results. Of 89 infants born to HIV+ mothers, 14 are infected (HIV-inf) and 19 have seroreverted and are well (HIV-SR). 44 infants of indeterminate status and 12 lost to follow-up were excluded from analysis. 86 infants were born to HIV- mothers (born HIV-); 34 are lost. Immunologic test results are shown:

	CD4 Counts-mean (SD)			IgG Levels-mean (SD)		
	0-1mo.	3-6 mo.	9-12 mo.	0-1 mo.	3-6 mo.	9-12 mo.
HIV-inf	3048(1706)	1344(1129)	1346(329)	1526(324)	995(544)	2526(1013)
HIV-SR	3358(1337)	3342(922)	3456(846)	1148(404)	619(452)	865(447)
Born HIV-	2863(1316)	3950(1643)	3106(1658)	1163(372)	517(193)	731(228)
	p=0.5	p=0.0015	p=0.15	p=0.05	p=0.0025	p=0.0001

6/7 infected infants tested vs 4/11 HIV-SR and 22/53 infants born HIV- had elevated IgG at 0-1 mo. 9/10 infected infants tested vs 2/15 HIV-SR and 2/31 infants born HIV- had elevated IgG during the follow-up period. 5/5 infants tested who developed opportunistic infections had CD4 counts <1000/mm^3 during the course of illness vs 1/6 other infected infants tested, 0/15 HIV-SR infants tested, and 3/46 infants born HIV-. Conclusions Elevated IgG is an early and consistent sign of HIV infection. Low CD4 counts are seen primarily in association with opportunistic infections and were not observed at birth.

M.B.O.5

PREDICTIVE VALUE OF BETA 2 MICROGLOBULIN LEVEL IN SERUM FROM CHILDREN BORN TO HIV INFECTED MOTHERS

Di Maria, Hugo (1); Toubert, M.E. (4); Schlageter, M.H. (4); Dormont, D. (2,3); Lasfargues,G (1); and Courpotin, C. (1).
(1) : Hopital Trousseau, Paris, France; (2) CRSSA, Fontenay aux Roses, France; (3) Institut Pasteur, Paris France; (4) Hopital Saint Louis, Paris, France.

Objectives: To determine the predictive value of beta 2 microglobulin seric level in infants born to seropositive mothers, though, in several studies, high level of beta 2 microglobulin appears to be pejorative predictive parameter in HIV infected adults.
Methods: From 1985 to 1989 , 29 children born to HIV infected mothers were evaluated in beta 2 microglobulin seric level at neonatal period, and after one month of live .12 children (group A) have documented HIV infection ; 17 children (group B) do not have any biological symptom of HIV infection (11 months of survey at least , negative viral cultures and no seroconversion). Beta 2 microglobulin amount was determined in serum using radioimmunoassay. Statistics were performed according to non parametric methodology.
Results: In neonatal period , it doesn't appear any statistically significant difference of beta 2 microglobulin levels between the two groups , probably related to the transplacental passage of the beta 2 microglobulin . After one month , mean levels are : 4 mg / l in group A (infected) and 1,98 mg / l in group B (no biologic sign of HIV infection), these populations being statistically different ($p<0,03$). From the 12 HIV infected children : 1) among the 8 children whose beta 2 microglobulin level was greater than normal value, 7 developped AIDS related symptoms within 1 to 5 months, one remaining asymptomatic. 2) 4 had normal levels: 3 seropositive asymptomatic and 1 who developped LAS . All children without biologic symptoms of HIV infection had normal beta 2 microglobulin level after one month of life, and none of them developped biological symptoms of HIV infection (11 to 37 months of survey).
Conclusion: After neonatal period, high level of seric beta 2 microglobulin is of pejorative prognosis in children born to HIV infected mothers.

M.B.O.6

HIV1 DNA DETECTION BY PCR FOR STUDIES ON PERINATAL HIV TRANSMISSION IN AFRICA.

Patricia Paterlini*; Lallemant-Lecoeur, S.**; Lallement, M.***; M'Pelé, P.*****; Larouze, B.**; Bréchot, C. * **** and Research Group on perinatal HIV1 infection in Congo.
*INSERM U.75, CHU Necker, Paris, **U.13/IMEA Claude Bernard, Paris, ***ORSTOM, Bondy, ****Hybridotest, Institut Pasteur, Paris, France, *****Programme National de lutte contre le SIDA (PNLS), Congo.

Objective. To investigate the feasibility and potential interest of PCR in studies on perinatal HIV1 infection in Africa.
Patients. Leucocytes blood samples (PBL) were obtained from HIV1 positive and negative mothers in Brazzaville (Congo). In this area a 4% rate of HIV1(+) is observed in mothers child clinics. 2 groups were analyzed. Group I : 14 newborns (1 day), 7 and 7 from HIV1(+) and (-) mothers. Group II : 13 babies (2 to 9 months) born from HIV1(+) mothers.
Methods. HIV1 DNA was tested strictly under code in PBL. PCR was performed with 60 cycles and 3 sets of primers (Pol and Env). Serology : Western-blot and ELISA.
Results. Group I (newborns) : 5/7 and 2/7 scored (+) for HIV1 DNA sequences in newborns from HIV1(+) and (-) mothers respectively. The 2 Western-blot(-) mothers of PCR(+) newborns were however found (+) with a quick test. GroupII (babies) : 9/13 scored (+) for HIV1 DNA. 6/13 had clinical symptoms consistent with HIV infection and all scored (+) for PCR.
Conclusion. 1) Reliable results can be obtained with PCR on blood samples during studies conducted in Africa. 2) Our data likely indicate a high rate of maternal HIV transmission in this area. 3) PCR should be included in ongoing epidemiological studies in Africa.

Coordination des soins : le point de vue du personnel infirmier
Coordinating Care: Nurses' Perspectives

M.B.O.7 AN INTERDISCIPLINARY APPROACH TO AIDS CARE: ST. PAUL'S EXPERIENCE

Goldstone, Irene, St. Paul's Hospital, University of British Columbia, Vancouver, British Columbia, Canada.

Objective: To describe the coordinated, interdisciplinary management of patients with HIV infection at St. Paul's Hospital (SPH).

Since the early days of the AIDS epidemic it has been apparent that we are confronted with a biological and social challenge that does not fit a traditional model of patient care management. Recognising this, and that AIDS care does not fall within the purview of a single medical specialty, SPH has developed an interdisciplinary model of patient care. This model relies on the full participation of the family practitioners, medical specialists, hospital and home care liaison nursing staff, AIDS dedicated social workers, pharmacists and other related disciplines. The primary focus is on the clinical care of patients, with a special emphasis on identifying and providing direction for the resolution of psychosocial problems. There is a high degree of commitment to research and education at all levels. There is an emphasis on quality of life and treatment through outpatient care which is greatly facilitated by a dedicated HIV Clinic and close liaison with community support services. These services have allowed the successful expansion of our AIDS program to 5,367 inpatient days (1988-89) and 10,000 outpatient visits (1988). This represents 75% of the AIDS related care in the province of British Columbia.

M.B.O.8 THE IMPACT OF AIDS ON FAMILIES OF HAEMOPHILIACS IN WALES

Beese, Jacqueline, University of Wales College of Medicine, Cardiff, South Wales, U.K.

Objective. To describe the impact of Aids on the families of affected Welsh Haemophiliacs.
Anyone involved with haemophiliacs has to be impressed by their courage in getting on with the business of living in spite of the debilitating nature of the disease. Now over fifty individuals living in Wales are facing a new obstacle - HIV infection as a result of contaminated blood products; six have already died. The sex linked mode of inheritance means that more than one family member may be affected. Method. The data on which the study is based was collected over a period of twelve months from the families of adult males and children attending a haemophilia centre. The qualitative holistic approach of grounded theory is used to explain the subjective dimensions of their human experiences.
Results. At least one wife has seroconverted, others have not made love since their husbands were found to have contracted the Aids virus, largely due to the fact that their husbands recoil from physical strain. Parents have a huge burden to bear, some have experienced publicity surrounding the death of a child, several having other affected children face stigma and social isolation, others live in fear of being identified.
Conclusion. Marriages are under stress, there is evidence of poor communication between partners who frequently keep the knowledge to themselves, wondering how long they are going to be able to keep it quiet.

M.B.O.9 THE CHALLENGE FACING NURSING IN CENTRAL AFRICA

Kopolo, Olive. Department of Nursing, University Teaching Hospital, Lusaka, Zambia.

M.B.O.10 A COMPARISON OF THE PROJECTED NURSING CARE NEEDS OF HOSPITALIZED AIDS AND NON-AIDS PATIENTS

Lydia Ivanus, I. Corbett, S. Grover, et al.
Department of Nursing, Royal Victoria Hospital, Montreal, Québec, Canada.

Objective. To confirm the observation that the nursing care requirements of hospitalized AIDS patients (AP) are greater than those of hospitalized non-AIDS patients (NAP).
Method. Staff nurses used the patient classification system, Project of Research in Nursing (PRN) to quantify projected patient nursing care needs. This validated tool describes patient care needs by integrating workload measurement with the nursing process (assigning a value to each anticipated nursing intervention: debridement of wound = 6 points). The advantage of this approach is that it allows for the individualization of the measurement (time) of care required (not given) as scheduled for the patient. Daily PRN scores of 69 AP admitted in 1986 were retrospectively collected from nursing records. Two matched controls without AIDS, admitted concurrently to the same service, were sought for each AP resulting in 129 NAP on whom data could be found.
Results. The mean daily projected nursing care hours were: 16±10.5 for all hospitalized AP, and 10.9±7.4 for all hospitalized NAP. Patients requiring an intensive care setting: 35.8±21.6 for AP and 24.3±18.1 for NAP. Patients admitted to a nursing unit: 14.5±5.2 for AP and 10.0±4.8 for NAP. The mean length of stay for all AP was 24.6±26.4 and 11.9±10.4 for NAP.
Conclusion. Nurses estimated that AP require 52% more nursing care than NAP. This information supports nursing judgment and intuition by providing an objective measurement of workload which is valuable for resource management.

M.B.O.11 HOME NEEDS (CARE FOR AIDS PATIENTS)

Maynard, Pat. St. Elizabeth Nursing Home, Don Mills, Ontario, Canada.

Diagnostic et histoire clinique de l'infection par le VIH
Natural History and Diagnosis of HIV Infection

M.B.0.12 CHANGING PATTERN OF PNEUMOCYSTIS CARINII INFECTIONS

Hopewell, Phillip C. San Francisco General Hospital, San Francisco, California, U.S.A.

M.B.0.13 ANIMAL MODELS OF *PNEUMOCYSTIS CARINII* PNEUMONIA

Queener, Sherry F.; Bartlett, M. S.; Smith, J. W.
Indiana Univ. School of Medicine, Indianapolis, Indiana.

Objective. To develop a model of *Pneumocystis* pneumonia that would consistently produce a good yield of uniformly heavily infected animals suitable for drug testing or biochemical work.
Methods. Virus-free female Sprague-Dawley rats weighing 130 - 150 gm are immune suppressed by: a) cortisone acetate 250 mg/kg twice weekly, b) dexamethasone 1.2 mg/L in drinking water continuously, or c) methylprednisolone 40 mg/kg once weekly. Drinking water contains 0.5 gm/L tetracycline. Rats receive standard laboratory chow (23% protein). Transtracheal injection of 10^6 to 10^7 organisms is performed 4 to 7 days after the start of immune suppression.
Results. Virus-free rats used in these studies are also *Pneumocystis*-free. The rate at which they become infected naturally depends upon the level of exposure to already-infected animals. Transtracheal inoculation of these rats speeds the development of heavy *Pneumocystis* infections so that rats may be harvested for biochemical work by 6 to 7 weeks. Rats are also more uniformly infected by this mechanism. Tests of drug for therapy may be started at 4 weeks and harvested at 6 to 7 weeks; for relapse studies a subset of each test group is continued on immune suppression without further drug therapy for an additional 2 to 4 weeks. Tests of drugs for prophylaxis start at the time of inoculation and run 6 weeks.
Conclusion. Transtracheal inoculation of *P. carinii* into immune suppressed rats produces consistently heavy infections and allows efficient drug testing in therapy, prophylaxis and relapse protocols. These heavily infected rats are also good sources of organisms for biochemical studies.

M.B.0.14 TREATMENT OF *PNEUMOCYSTIS CARINII* INFECTIONS: ANTIMICROBIALS

Toma, Emil. Hôtel-Dieu de Montréal and Université de Montréal, Québec, Canada.

The current treatment for *Pneumocystis carinii*(PC) infection are efficacious in more than 90% of cases. Different factors contributed to this progress: better educated physicians and patients; earlier diagnosis; better management; extended knowledge of pharmacokinetics of PC drugs; the effect (s) of AZT treatment, etc. However, the incidence of adverse reactions is high and the initial therapy should often by changed. Several therapeutic principles are now recognized, such as: do not treat empirically; make an early specific diagnosis; non-specific tests (except for blood gases at rest and exercise), are not cost-effective and delay the etiologic diagnosis; consider PC also in subtle or atypical cases; mild to moderate clinical forms could be treated orally; dosage modifications have few effects on adverse reactions or survival; in the presence of side effects better change the initial therapy, etc. For patients failing and/or unable to tolerate "conventional" therapy 3,still investigational, approaches are available: eflornithine, trimetrexate/leucovorin and clindamycin/primaquine; however their effectiveness, safety and recurrence rate are not appropriately assessed. New therapeutic regimens will be probalby suggested but all these treatments should be evaluated in well-designed controlled clinical trials and not to be used indiscriminately.

M.B.0.15 NEW DEVELOPMENTS IN THE TREATMENT AND PROPHYLAXIS OF PCP

Julio S.G. Montaner,* MD, FRCP(C), Director of AIDS Research Program
St. Paul's Hospital, University of British Columbia, Vancouver, BC, Canada

Despite a number of therapeutic advances, PCP remains the most common serious opportunistic infection in HIV-infected individuals. Two recent developments have shown promise in potentially altering morbidity and mortality associated with this condition. These are:

Adjunctive Corticosteroid Therapy: previous retrospective work suggested that adjunctive systemic corticosteroids could have a favourable effect by reversing respiratory failure, hasten defervescence and minimizing side effects to commonly used antimicrobials. More recently, we have demonstrated in a placebo controlled trial that adjunctive oral corticosteroids (60 mg PO, OD for 7 days followed by a 14 day tapering course) can also prevent the development of clinical acute respiratory failure in patients with moderately severe PCP. This has had a significant beneficial impact, not only decreasing mortality but also improving quality of life. A welcome spin off of this approach has been the decrease in admissions to the Intensive Care Unit and earlier discharge of patients with AIDS-related PCP.

PCP Prophylaxis: the experience in leukemic patients and more recently the report by Fischl et al focused our attention on the great potential value of PCP prophylaxis in AIDS. Unfortunately this was difficult to instrument because of the generally poor tolerance among HIV-infected individuals of the commonly used prophylactic regimens. We have recently concluded a Canadian cooperative placebo controlled trial of the efficacy and safety of aerosolized pentamidine for the secondary prophylaxis of AIDS-related PCP. Patients were randomly allocated to receive pentamidine 60 mg/dose or placebo. The drug was delivered via a hand held ultrasonic nebulizer (FISONEB®, MAD = 2.5-5.0 microns) over 15 to 20 minutes. Patients received an induction treatment consisting of 5 doses in 14 days followed by one dose bi-weekly thereafter. 162 patients were randomized at the time that the study was terminated. Of the 32 cases of PCP identified during the follow-up period, 27 of them occur among the 78 placebo treated patients while only 5 occur among the 84 patients receiving active therapy ($p<.001$ chi sq). Both groups were similar in terms of baseline data and median follow-up. Side effects were uncommon and generally well tolerated. In contrast to previous reports, the tolerance of aerosolized pentamidine was extremely good and overall adverse events were rare. Our study conclusively demonstrates that aerosolized pentamidine is highly effective in the prevention of AIDS-related PCP.

Oral Manifestations of AIDS

M.B.0.16

ORAL PATHOLOGY IN 105 HIV-REACTIVE PATIENTS IN BUENOS AIRES

Casariego, Zulema*; Cahn, P*; Pérez, H*; Casiró, A*; Grinberg, N*; Muchinik, G**, et al.
*Hospital Fernández, **IIHEMA, Academia Nacional de Medicina, Buenos Aires, Argentina.

Objective. To present the first systematic study on oral pathology in HIV-reactive patients (HIV+Pt) in Latin America.
Methods. A total of 105 HIV+Pt with lesions in the oral cavity were examined over 8 months (Apr.-Dec.'88) by means of clinical exams, dental-eye photograph, culture and biopsy.
Results.

Pathology	HIV+	%	Pathology	HIV+	%
Erythematous candidiasis	101	96.1	Angular cheilitis	21	20
Villous leukoplasia	19	18	Erythema	16	15.2
Prog.ulcerative parodontitis	9	8.5	Pseudomembranous candidiasis	9	8.5
Gingivitis	9	8.5	Herpetic stomatitis	6	5.7
Hypertrophic gingivitis	5	4.7	Hyperplastic candidiasis	4	3.8
Petechiae - Telangiectasis	4	3.8	Ulcer-necrosing gingivitis	3	2.8
Recurring ulcerative aphthae	2	1.9	Xerostomia	1	0.9

Conclusion. Candidiasis in its different forms was the most frequently found lesion (64.1%); villous leukoplasia was the second one. All the HIV+Pt studied belonged to groups II and III provided by the CDC. Only 9 Pt had pseudomembranous candidiasis -updated and well-known name of this disease. Early or very small lesions of the oral cavity are likely to be regarded too lightly by clinicians if the latter lack the skilled contribution of stomatologists. A new classification of AIDS-related diseases should include appropriate stomatological information.

M.B.0.17

ORAL MANIFESTATIONS OF HIV INFECTION IN AFRICAN PATIENTS

Mugaruka, Z.*; Perriens, Joseph **; Ngaly, B.***; Baende, E.**; Kahotwa, J.**; Kapita, B.*. *Mama Yemo Hospital, **Projet SIDA, ***National AIDS Control Programme, Kinshasa, Zaire.

Objective. To describe type and prevalence of the oral manifestations associated with HIV infection in hospitalized African patients.
Methods. Consenting patients of a systematic 50% sample of all hospitalisations between 10/15/1988 and 30/11/1988 in 2 internal medecine wards of Mama Yemo Hospital in Kinshasa, Zaire, were tested for HIV antibodies and underwent an exam of the oral cavity.
Results.

	HIV (+) (n=100)	HIV (-) (n= 88)	P-value
Any oral complaint	88%	48%	.0000
Any type of candidiasis	62%	26%	.0000
Pseudomembraneous candidiasis	31%	6%	.0000
Atrophic candidiasis	30%	21%	NS
Hyperplastic candidiasis	2%	0%	NS
Parotid swelling	6% *	0%	.07
Kaposi sarcoma	5%	0%	NS
Aphtous ulcers	5%	0%	NS
Necrotising gingivitis	4%	1%	NS

* Two patients had bilateral and 4 unilateral chronic painless parotid swelling.
Condylomata and herpes simplex were rare (1%), and present in HIV(+) patients only. Periodontitis, and hairy leukoplakia were not observed.
Conclusion. Oral disease, especially candidiasis, is common in hospitalized Zairian patients with HIV infection. Hairy leukoplakia seems infrequent in this population. Chronic painless parotid swelling was highly predictive for HIV seropositivity.

M.B.0.18

DEMONSTRATION OF EBV-DNA PRIOR TO THE OCCURENCE OF OHL AND ITS CORRELATION WITH THE CLINICAL STATUS

Näher, Helmut*; Freese, U.K.**; Gissmann, L.**; von Knebel Doeberitz, C.**; Petzoldt, D.*; Greenspan, J.S.*** et al.
*Ruprecht-Karls University, Heidelberg, FRG, **Deutsches Krebsforschungszentrum, Heidelberg, FRG, ***University of California, San Francisco, U.S.A.

Objective: To investigate the prevalence of Epstein-Barr-virus (EBV) and human papilloma virus (HPV) in epithelium of the tongue of HIV patients and control persons.
Methods: Filter in-situ hybridisation assays for the detection of EBV-DNA and HPV-DNA were used. The clinical status of the HIV patient was determined according to the Walter-Reed classification system (WR).
Results: Whereas EBV-DNA could not be detected except at low concentrations in 3 of 35 HIV-negative control persons, HIV patients with oral hairy leukoplakia (OHL) contained EBV-DNA at high concentrations. In contrast to the unambiguous presence of EBV in OHL, none of the specimens scored positive for HPV-DNA types 6, 11, 16 and 18. EBV-DNA could also be demonstrated in the epithelium of the tongue of 19 out of 32 HIV patients without OHL. 3 of these patients developed OHL within 4 to 7 months. On the average, HIV patients without OHL were WR 3.44 and HIV patients presenting with OHL WR 4.36 ($p < 0.07$). HIV patients with detectable EBV-DNA were WR 4.05 and HIV patients without EBV-DNA WR 2.54 ($p < 0.0004$).
Conclusion: The demonstration of EBV in OHL means not only a silent carrier status, but in the absence of HPV-DNA an essential role of EBV in the pathogenesis of OHL. Moreover, the clinical status of HIV patients could be more reliably predicted by the demonstration of EBV-DNA than by the occurence of OHL. Thus the demonstration of EBV-DNA may be an earlier and more valuable prognostic marker for the progression of the HIV disease than the occurence of OHL.

M.B.0.19

SEXUAL PRACTICES AS RISK FACTORS FOR CANDIDIASIS AND HAIRY LEUKOPLAKIA: THE ORAL AIDS EPIDEMIOLOGY PROJECT.

Feigal, David W.*; Greenspan, D.**; Overby, G.**; Moss, A.*; Rutherford, G.***; Greenspan, J.S.**
Schools of * Medicine & ** Dentistry, University of California, San Francisco, The Oral AIDS Center; *** Department of Public Health, San Francisco, CA, U.S.A.

Objective: To test the hypothesis that some sexual practices would increase the risk for oral lesions caused by infectious agents, ie., candidiasis (CD), hairy leukoplakia (HL).
Methods: The Oral AIDS Epidemiology Project is a collaborative project with several prospective cohorts of HIV infected individuals where the examiners (who are blind to serostatus) have been trained in the diagnosis of oral lesions, and use a common oral exam form. The cohorts collect extensive histories of sexual behaviors and in addition to detailed physical exams collect blood for immunologic measures. Odds ratios were used to compared sexual practices in seropositive gay men with normal oral exams and those with specific lesions. Only men with HL (n=110) candidiasis (n=51) or a normal exam (n=301) in the 1987 exam are included in this analysis. 34 men reported oral-anal sex and 245 reported oral-genital sex.
Results: Odds ratios *[95% C.I.]*

	Candida	Hairy Leukoplakia
Oral-Genital Sex	2.33 *[.79, 6.90]*	3.87 *[1.84, 8.12]*
Oral-Anal Sex	1.00 *[.21, 4.82]*	.94 *[.38, 2.34]*

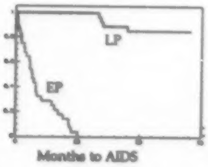
Conclusion: The increased risk of both infections with oral-genital sex implies that both may be contributed to by sexual activity. The low prevalence of oral-anal sexeven if under reported, makes it unlikely to be as important as other sexual practices. Conversely HL and CD may be markers for men who continue to be sexually active and may offer possible outcome measures for behavioral intervention studies in healthy seropositive men designed to promote safer sexual practices.

M.B.0.20

RISK FACTORS FOR RAPID PROGRESSION FROM HAIRY LEUKOPLAKIA (HL) TO AIDS.

Greenspan, Deborah*; Greenspan J.S.*; Overby G.*; Borowsky C.**; Hollander, H.**; Feigal, D.W.**. * Schools of Dentistry & **Medicine, University of California San Francisco, Oral AIDS Center SF CA, USA.

Objective. To determine factors predictive of early progression to AIDS after HL.
Methods. This case control study defined outcome as early progression (EP) or late progression (LP) based on whether AIDS developed within 1000 days. 27 patients with LP and 28 with EP were selected from the earliest cases in a cohort of 508 patients who have been diagnosed at the Oral AIDS Center at UCSF since 1982. Complete follow-up was obtained from patient and family contact, referring physician and hospital records, and state death records.
Results. Some risk factors most likely reflected duration of HIV infection. Hepatitis B and syphilis infection were both associated with an odds ratios of 4 for early progression, and probably were markers for men whose sexual activities were high risk early in the epidemic. Persistent generalized lymphadenopathy, *Herpes zoster*, *H. simplex*, and oral candidiasis were not more frequent in the EP than LP groups. Other risk factors reflect current immunologic competence. T cell subsets were not available from this early cohort, but skin testing was available in 29. Skin test anergy for candida was strikingly predictive; 17 of 19 nonreactive were in the EP group; all 10 of who reacted were in the LP group.



Conclusion. Rapid progression from HL is not universal. Positive candida skin testing predicts longer time to AIDS.

M.B.0.21

ORAL KAPOSI'S SARCOMA IN AIDS: MANAGEMENT WITH INTRALESIONAL CHEMOTHERAPY

Epstein, Joel*; Lozada-Nur, F.**; McLeod, W.A.*** and Spinelli, J.****
*Cancer Control Agency of B.C.; Vancouver, Canada, **UCSF; San Francisco, USA, ***St. Paul's Hospital; Vancouver, Canada, ****Cancer Control Agency of B.C.; Vanc., Canada

Objective. To observe the efficacy of local intralesional Vinblastine in management of oral Kaposi's sarcoma (KS).
Methods. All patients had histologically proven intraoral KS. Patients with bilateral palatal lesions were selected, one side was treated with intralesional 0.2 to 0.8 mg of Vinblastine (0.2 mg/ml) following local anesthesia. Patients were seen every two weeks following injection. In addition to palatal lesions, lesions affecting the gingiva and tongue were treated using the same technique.
Results. 10 patients with bilateral palatal lesions were treated. All were homosexual/bisexual males, demonstrating HIV positivity and meeting the diagnostic criteria of AIDS. Age range - 24 to 56 years (mean 37.6 years). After a single injection with Vinblastine, the mean reduction in tumor size of the palatal lesions was 51% While, increase of the untreated KS occurred in 7 of 10 patients. 4 patients received repeat treatments to the same lesions with an overall reduction in size of 71% Combining the results with 1 or 2 injection treatments, the mean reduction in surface area of the palatal lesions was 63% Follow-up was a mean of 3.6 months. Discomfort following injection was assessed using visual analogue scales with pain of 24 to 48 hours reported: 2 patients reported no pain, 3 patients mild pain, 4 moderate pain and 1 severe pain. Pain was controlled with oral analgesics. The gingival and tongue lesions showed more complete reduction in size than the palatal lesions treated.
Conclusion. The use of intralesional Vinblastine appears to provide good palliation of oral KS lesions without significant side-effects due to the treatment.

Nouvelle technique de diagnostic rapide et améliorée
New Improved Rapid Diagnosis

M.B.O.22 IMMUNOLOGICAL CHARACTERIZATION OF RECOMBINANT HIV ENVELOPE PROTEINS

Lautenberger, James A.*; DuBois, Garrett C.**; Samuel, Kenneth P.**; Showalter, Stephen D.**; Zweig, Martin**; and Papas, Takis S.*
*Laboratory of Molecular Oncology, National Cancer Institute, Frederick, MD 21701, USA. **Program Resources Incorporated, Frederick Cancer Research Facility, Frederick, MD 21701, USA.

A set of nine proteins essentially encompassing the entire HIV envelope gene have been synthesized in *Escherichia coli*. Since the levels of expression range from 2 to 20 per cent of the bacterial mass, it has been possible to purify several of these proteins in milligram quantities. The purification procedures involve extraction with salts and detergents followed by high performance liquid chromatography (HPLC). The identity of several of the proteins has been confirmed by determination of the amino-terminal amino acid sequence. The immunological properties of these proteins were analyzed by the immunoblot (Western blot) procedure using a panel of sera from HIV positive individuals. Eight of the proteins reacted strongly with at least some of the sera indicating that there are a large number of determinants in the HIV envelope that can elicit an immune response in humans. Six of the sera showed some degree of reaction with all positive sera tested indicating that they have potential use as antigens in diagnostic tests. Two of these proteins, from clones 318 and 566, were tested in an ELISA assay. While both antigens reacted with HIV sera, the protein from clone 566 was found to be more sensitive and specific than that of clone 318. Clone 566 is from the transmembrane (gp41) region. The sensitivity and specificity of the ELISA using clone 566 protein was found to be equivalent to an ELISA using immunoaffinity-purified native gp41. This recombinant protein thus can be the basis of a test for HIV infection that does not involve the use of viral products. We have produced several monoclonal antibodies to the recombinant proteins and are using them to map the immunological determinants of the native envelope gene.

M.B.O.23 ANTIBODY RESPONSES TO ACCESSORY GENE PRODUCTS IN HIV-1 INFECTION.

Reiss,P.*; De Ronde,A.*; Lange,Joep*; De Wolf,F.*; Debouck,C.**; Goudsmit,J.*; et al. *Academic Medical Centre, University of Amsterdam, the Netherlands. ** Dept. of Molecular Genetics, Smith Kline and French Lab., Pennsylvania, USA.

Objective. Determination of Ab responses against nef-, rev-, and tat-gene products of HIV-1 in a cohort of 134 initially asymptomatic HIV-1 seropositive men and 72 men who seroconverted for Ab to HIV-1 structural proteins; analysis of possible relationships between Ab responses to HIV-1 nef, rev, and tat vs. disease progression and serological and immunological markers predictive of rapid disease progression.
Methods. Enzyme-immunoassays based on E.coli expressed nef-, rev-, and tat-gene products were performed on sequential sera from the above men.
Results. In 68% nef-specific Ab, once detected, persisted. In some men nef-specific Ab were transiently (7%) or intermittently (5%) detectable. Nef-specific Ab were not found in 20%. An absent, or transient, or intermittent nef-specific Ab response was significantly associated with the absence of Ab to core proteins, with core antigenaemia and with low CD4+ cell counts, i.e. profiles predictive of rapid disease progression. Although more cases of AIDS and AIDS-related disease (21/86 vs 28/180) occurred in the nef-Ab negative group than in the positive group, this difference did not reach significance. Data regarding Ab responses against HIV-1 rev and tat will also be presented.
Conclusion. Expression of HIV-1 accessory gene products in vivo may reflect disease progression in HIV-1 infection.

M.B.O.24 SEROREACTIVITY TO HIV-1 VIF, TAT, AND NEF PROTEINS

Wieland, Ulrike*, Jassoy, Ch.*, Tenscher, K.*, Wolber, V.**, Kuehn, J.*, and Braun, R.*
*Institute for Medical Virology, University of Heidelberg, Im Neuenheimer Feld 324, D-6900 Heidelberg, and ** Max-Planck Institute for Medical Research, Jahnstr. 29, D-6900 Heidelberg, F.R.G.

Objective. Determination of the prevalence of antibodies against HIV-1 vif, tat, and nef proteins in sera of HIV-1 infected patients from different clinical stages.
Methods. HIV-1 vif, tat, and nef genes were cloned in procaryotic vectors and were expressed in total (tat) or as MS-2 fusion proteins (vif, nef). These proteins were employed in immunoblot and RIPA-PAGE experiments. The specificity of reactions was confirmed by competition experiments and with control sera from HIV negative patients.
Results. Analysis of 100 serum samples showed a low percentage of sera reactive with vif and tat (15% and 25%, respectively) in asymptomatic HIV positive carriers. This percentage increased to 75% and 40%, respectively, in patients with AIDS. In contrast, 85% of the sera investigated showed a reactivity with the nef protein regardless of the stage of disease.
Conclusion. Our data indicate an early antibody respon[illegible]f and a relatively late immune response to tat and vif.

M.B.O.25 A RAPID AND SIMPLE PROCEDURE FOR FIELD TESTING OF HIV-1 ANTIBODIES

Ritterband, M. Herzberg, M., and Falk Fish
ORGENICS Ltd., Yavne, ISRAEL

Objective. Evaluation of the HIV-1 antibodies ImmunoComb kit.
Methods. Serum and plasma specimens were tested in the HIV-1 Antibody ImmunoComb™ test kit. Fifty microliters of each specimen are inserted into a specimen well of a Developing Plate, containing all the reagents required for running the ELISA procedure to completion. A mixture of 3 synthetic polypeptides, representing two gp41 epitopes and one gp120 epitope (gp160 conserved), are attached in the form of spots to projections ("teeth") of a flat plastic card. The ImmunoComb card is inserted into the specimen-containing wells to allow attachment of the anti-HIV-1 antibodies to the polypeptides. Thereafter, the card is moved through compartments containing washes, alkaline phosphatase anti-human IgG conjugate and BCIP-NBT chromogenic system. Positive specimens result in a purple-grey spot at the location of the peptide mix. The whole procedure takes 30 minutes at room temperature and can be carried out in a non-laboratory environment. Sensitivity and specificity were calculated relative to the Western Blot results.
Results. Over 3000 specimens, including early seroconvertors and Western Blot indeterminates were tested at various medical centers in Europe and Israel. The ImmunoComb kit demonstrated 99.2% sensitivity and 99.64% specificity.
Conclusion. The use of a conserved epitope and high local concentration of antigen makes the ImmunoComb procedure a rapid and accurate assay kit for the detection of HIV-1 antibodies, which is operable anywhere.

M.B.O.26 A RAPID WHOLE BLOOD APPLICATION FOR HIV ANTIBODY TESTING USING LIPOSOME-BASED TECHNOLOGY.

Hilberg, Charles*; Duschl, D.; Blackwell, J.; Huff, J.; Britz, J.; Smialek, J.**.
*Becton Dickinson and Company, Sparks, Maryland, USA, **Office of the Medical Examiner, Baltimore, Maryland, USA.

The demand for more rapid HIV antibody testing has resulted in the development of a 5-minute, whole blood test, storeable at room temperature, which eliminates the need for conventional cell separation methods. Purified inactivated HIV cell-lysate antigen is immobilized on a membrane incorporated into a flow-through device. Diluted human whole blood is applied to the device and washed. The liposome-based detector reagent is added, and the reaction is visually read. A pink triangle indicates a reactive result; a pink dot used as an internal control indicates a negative result. Preliminary results from a study utilizing 185 whole blood specimens obtained from cadavers yielded a correlation of 99%, when compared to a licensed HIV ELISA. Correlation with Western blot was 100% for Western blot positive specimens. Two reactive specimens were non-reactive by ELISA and Western blot indeterminate, resulting in a specificity of 98.9%. These data demonstrate the efficacy of a rapid test using whole blood for the Medical Examiner's Office, Emergency Room, physician's office, and third world countries where instrumentation and cold storage are not readily available.

M.B.O.27 A MULTISITE STUDY OF A PARTICLE AGGLUTINATION TEST FOR DETECTION OF HIV ANTIBODIES

Schiff, Robert*; Piccirilli, R.**; Busch, M.***; Peetoom, F.****; and Tegtmeier, G.*****.
*Schiff & Company, N. Caldwell, NJ, **NE Penn. Region ARC, Wilkes Barre, PA, ***Irwin Memorial Blood Bank, San Francisco, CA, ****ARC Blood Services, Portland, OR, *****Community Blood Center of Greater Kansas City, MO.

Objective. To compare performance of the SERODIA-HIV Assay to screening tests for the detection of HIV antibody.
Method. Blood donor and library samples were collected at 4 blood banks. Samples were tested by the SERODIA-HIV Assay (Fujirebio, Inc., Japan) using the FASTEC 901 pattern reader and assayed by either the Abbott or Genetic Systems Enzymeimmunoassays. Results were compared on initial and repeat testing. "Western Blot" was performed on samples which were repeat reactive in any of the assays.
Results. On initial testing of 10,481 samples agreement between the screens and SERODIA HIV was 98.8%. After retesting, the agreement was 99.3%. Of 152 samples that were repeat reactive by the screening tests and SERODIA and tested by Western Blot, 143 were positive, 4 indeterminate, and 3 negative. Of 69 samples that were screening test positive and SERODIA negative and then tested by Western Blot, 68 were negative and 1 was indeterminate. 4 samples that were screening test negative and SERODIA positive showed 2 positive by Western Blot, 1 negative and 1 indeterminate.
Conclusion. SERODIA appeared more sensitive than the Genetic Systems or Abbott procedures, especially during dilution studies, showed no false negatives and had fewer false positives than the screening tests.

Traitement des infections associées à l'immunodéficience causée par le VIH
Management of Infections Associated with HIV Immunodeficiency

M.B.0.28 TOXOPLASMOSIS

Pechère, Jean-Claude. Hôpital Cantonal de Genève, Genève, Suisse.

M.B.0.30 TUBERCULOSIS (TB) AND ATYPICAL MYCOBACTERIA IN PATIENTS WITH HIV INFECTION

Chaisson, Richard E.
Johns Hopkins University, Baltimore, MD USA

TB is common in HIV-seropositive populations with a high prevalence of M. tuberculosis infection. TB is often an early AIDS related opportunistic infection, occurring when CD4 cell counts are still relatively high (>200/ul). Clinical manifestatious may be atypical, especially in extremely immunosuppressed patients, though 60-80% of patients have pulmonary disease. Common radiographic findings include diffuse infiltrates and adenopathy. Tuberculin reactivity is found in 40 to 80% of patients. Response to standard antituberculosis therapy is generally excellent; lifelong therapy may not be necessary. Prevention of tuberculosis with prophylactic treatment of tuberculin-reactive HIV-seropositive persons is an urgent public health priority.

M. avium-complex (MAC) is a late complication of HIV-related immunosuppression. Most MAC disease is probably a result of recent infection, and all HIV risk groups are equally affected. Several distinct clinical syndromes are associated with MAC infection. While MAC causes considerable morbidity, its contribution to mortality is unclear. Treatment is difficult as most isolates are resistant to standard antituberculosis drugs. Studies in animal models and limited human data suggest that newer regimens may control MAC disease. Prevention of MAC infection may be possible with prophylactic therapy.

M.B.0.32 CRYPTOSPORIDIOSIS, ISOSPORIASIS AND MICROSPORIDIOSIS

Pearl Ma., St. Vincent's Hospital & Medical Center of NY

Explosive, chronic, fatal, nonbloody diarrhea with/without dissemination pose a very serious management problem in AIDS, especially those caused by Cryptosporidium Isospora, belli, and Microsporidia. These protozoans are easily detected in stool specimens using acidfast or immunofluorescent staining procedures, except Microsporidia which has not been demonstrated in stool and thus requires intestinal biopsy. Transmission is mostly fecal-oral, sexual, water/food borne, animal contact and possibly inhalation. Risk factors include travel to tropical countries, homosexuality immunocomprised, etc. Disseminated infection involves cholecystitis, hepatitis, pulmonary infection, for Cryptosporidium and myositis hepatitis for Microsporidia. Although Cryptosporidiosis in nonimmunocomprised host is self-limited, in AIDS, it is resistant to multiple therapies. Spiramycin and transfer factor have limited success. Currently, the most promising treatment is hyperimmune bovine colostrum from cows vaccinated with cryptosporidial antigen given to AIDS associated symptomatic patients resulting in long term remission. Isosporiasis with a much lower incidence than cryptosporidiosis is less devastating. Response to atabrin and sulfamethoxazole has been noted with/without recurrences in some earlier infections. Little is known of Microsporidia, the newly recognized pathogen in homosexual men with AIDS. Cases known so far are all fatal. In conclusion, drastic research is definitely needed to reduce high morbidity and mortality of these opportunistic infections in AIDS.

M.B.0.29 "CRYPTOCOCCOSIS"

Sande, Merle A. San Francisco General Hospital Department of Medicine, University of California. San Francisco, CA. USA.

M.B.0.31 HUMAN CYTOMEGALOVIRUS (HCMV) INFECTIONS IN AIDS: DIAGNOSIS AND ANTIVIRAL TREATMENT.

Gerna Giuseppe; Revello M.G.; Minoli L.; Grossi P.; Percivalle E.; Parea M.
Institute of Infectious Diseases, University of Pavia, and IRCCS Policlinico San Matteo, 27100 Pavia, Italy.

Objective. To correlate HCMV antigenemia and viremia with symptoms and ganciclovir (GCV) treatment in AIDS patients with sistemic HCMV infections. Methods. Antigenemia was determined in peripheral blood polymorphonuclear leukocytes (PMNLs) by IFA using a MAb to HCMV immediate early antigens (EA) (2h assay), and viremia by IFA staining of "shell vial" cell cultures (inoculated with a known number of PMNLs) 24h p.i. using a MAb to HCMV EA. Results. Overall, 33 of the 85 (38.8%) AIDS patients examined had reactivated HCMV infection, 14 of 55 (25.4%) had viremia and 7 of 30 (23.3%) both viremia and antigenemia. Of these, the 2 patients with a high number of positive PMNLs had high fever and were thus treated with GCV, with final disappearance of fever and virus from blood. Of 89 blood samples tested, 78 (87.6%) gave concordant results for both viremia and antigenemia, 9 (all taken during GCV therapy) were positive for antigenemia only and 2 for viremia only. Conclusion. By monitoring HCMV antigenemia and viremia it seems possible to anticipate onset of symptoms and to earlier initiate and carefully evaluate effectiveness of GCV treatment.

Infections concomitantes du SIDA
Concomitant Infections in AIDS

M.B.O.33 THE SPECTRUM OF NEUROSYPHILIS IN HIV-INFECTED INDIVIDUALS*

Reid, Stewart; Umedaly, H; Forrest, D; McLeod, A; Chan, R; Ruedy, J and Montaner, JSG. AIDS Research Program, St. Paul's Hospital, University of British Columbia, Vancouver, BC, Canada.

OBJECTIVE. To describe the spectrum of neurosyphilis in HIV-infected individuals.
METHODS. Retrospective review of all cases of neurosyphilis in HIV-infected individuals diagnosed at St. Paul's Hospital, over the 2 year period ending December 31, 1988.
RESULTS. Neurosyphilis was identified in 7 HIV-infected homosexual males over the study period. Only 1 patient was known to have AIDS at the time of diagnosis. All of them had a history of at least 1 episode of primary syphilis, up to 32 months prior to the diagnosis of neurosyphilis for which they received benzathine penicillin 2.4 million units IM. Presenting neurological symptoms were varied, including 1 or more of the following: headache (n=4), focal signs (n=4) and dementia (n=1). A characteristic maculopapular rash on palms and soles was present in 3 patients, and one patient also had a dark field positive penile chancre. One patient was completely asymptomatic. Serum RPR and CSF-VDRL were positive in all cases. CSF examination further revealed elevated proteins and increased cellularity (predominantly lymphocytes) in all cases. CT-scan of the head was abnormal in 2 cases (a non enhancing mass and multiple infarcts). All patients were treated with IV aqueous penicillin with daily doses in excess of 18 million units for 10 days. Clinical, serological and CT-scan improvement was documented in all cases.
CONCLUSIONS. The treatment of early syphilis as presently recommended may not be adequate in HIV-infected individuals who appear to be at an increased risk for progression to neurosyphilis. Its presentation can vary from completely asymptomatic to florid neurological deficit. Response to therapy appears to be uniformly good. Whether or not HIV-infected individuals who have positive syphilis serology should have routine CSF even in the absence of neurological symptoms, remains to be established. Prospective studies should be undertaken to further characterize the interaction between HIV infection and syphilis.

* Supported in part by the National Health Research Development Program (NHRDP), Health & Welfare, Canada.

M.B.O.34 CONCOMITANT SYPHILITIC AND HIV INFECTION

Calderon,W.*; Bono, G.**; Nigro, M.*; Grossi, P.*; Douville, Helene *.
* Infectious Diseases Dept. IRCCS S. Matteo Hospital- University of Pavia, Pavia, Italy.
** IRCCS C. Mondino-University of Pavia, Pavia, Italy.

Objective. Evolution of syphilis have been studied in a population of HIV with regard to progression mode and clinical pictures. Reciprocal interactions between syphilis and HIV have been suggested based on the observation of unusually aggressive forms of treponemic infection, particularly at the CNS level.
Methods. 37 homosexual, mean age 27 years, AIDS affected, have been observed. The following parameters were considered: clinical feature, course of the diseases, degree of immunodeficiency (Th/Ts), serological and immunological data (including CSF examination). In 36 cases, the clinical immunological feature of syphilis was not found to be significantly influenced by the superimposition of HIV infection nor by HIV related diseases. In only one case (G.A., male, 52 years, AIDS with PCP, CMV, HSV, Candida Th/Ts 0.52) presenting with clinically overt tabe dorsalis, the evolution to neurosyphilis seemed to be accelerated by HIV infection. Serological features (siero and liquor-isoelectrofocusing) indicated possible reinfection. The patient was treated with Bayercillina (Propicilline) standard dose.
Results. Except for the case above reported, the observations of our series does not confirm the hypothesis of a synergistic effect between the two infections. Reinfection, therefore by treponemic after HIV seroconversion seem to be the only event able to activate an unusual, aggressive forms of treponemic infection.

M.B.O.35 EFFECT OF PREVIOUS SYPHILIS INFECTION ON CSF ABNORMALITIES IN HIV-1 INFECTED INDIVIDUALS

McArthur, Julie H.; Alwood, K.; Fox, R.; Herman, C.; Hook, E.; McArthur, J.C. and the Multicenter AIDS Cohort Study. Johns Hopkins Medical Institutions, Baltimore, MD USA

Objective: To determine whether previous syphilis infection is associated with specific CSF abnormalities reflecting increased CNS HIV-1 activation in HIV-1 infected individuals.
Methods: 82 homosexual/bisexual men had CSF analysis as part of a prospective neurological study. Six additional HIV-1 seropositive individuals with previous syphilis infection were included. None had neurosyphilis, opportunistic CNS infections or HIV-1 related neurological disease. All had negative serum RPR or RPR titers <1:4 consistent with previous treatment and all had negative CSF VDRL. CSF analysis included cell count (WBC), total protein (Prot), oligoclonal bands (OCB), immunoglobulin concentration (IgG%), IgG index, blood brain barrier integrity (BBB), and HIV-1 isolation. Previous syphilis infection was assessed using serum FTA.
Results:

	CSF parameters: proportion abnormal							Blood CD4
	WBC ≥ 5	Prot ≥ 45	OCB ≥ 1	IgG% ≥ 6.1	IgG index ≥ 0.7	BBB ≥ 6.0	HIV Culture	Count (mean $\pm$ SD)
FTA + (n=30)	6/28	7/30	8/29	11/28	15/28	45/57	6/24	492 $\pm$ 373
FTA - (n=58)	20/56	15/58	21/56	20/57	27/57	15/20	15/58	528 $\pm$ 266

No significant differences were observed in comparing group means of the CSF parameters. An equally high rate of CSF abnormalities were noted in FTA + individuals as in the FTA - group.
Conclusions: Prior syphilis as assessed by FTA serostatus is not associated with a higher rate of CSF abnormalities. This suggests that previous syphilis infection does not lead to increased HIV-1 activation within the CNS.

M.B.O.36 TRAITEMENT DE LA TOXOPLASMOSE CEREBRALE PAR LA CLINDAMYCINE ET LE 5-FLUOROURACILE.

M. Eliaszewicz, M. Kirstetter, MC. Meyohas, J. Frottier; Hôpital Saint-Antoine, Paris, France.

La toxoplasmose cérébrale (TC) représente, au cours du SIDA, la plus fréquente des infections opportunistes du système nerveux central (25 à 40% des cas). L'association de référence pyriméthamine-sulfadiazine (PYR- SULF) fait preuve d'une toxicité telle que d'autres combinaisons thérapeutiques sont en cours d'évaluation : parmi celles-ci, in vivo PYR-clindamycine (CLIN), in vitro PYR-5fluorouracile (5FU) dont l'activité anti-toxoplasmique serait synergique. Nous rapportons le cas de 3 patients (pts) traités par CLIN-5FU en raison d'une intolérance hématologique absolue à la PYR et la SULF. Patients. 3 pts (2 hommes et 1 femme d'âge moyen 34 ans) n'ayant jamais reçu de sulfamide ou de PYR, sont traités pour une TC par SULF- PYR avec acide folinique. 2/3 pts reçoivent de l'AZT dont l'un pendant le traitement anti-parasitaire (thrombopénie périphérique sévère). SULF-PYR arrêté en moyenne à J24 pour aplasie grave est relayé par CLIN-PYR avec des interruptions itératives de 1 à 4 mois responsables de rechutes chez chacun des 3 pts. Méthodes: 2/3 rechutes sont traitées en perfusion par CLIN (4,8g/j)-5FU(1,5mg/KG/j) (1/10 de la posologie utilisée en chimiothérapie), la 3è étant traitée d'emblée par 5FU seule pendant 1 mois (hépatite à la CLIN). Lors de l'introduction du 5FU, 2/3 pts sont sevrés de tout traitement anti-parasitaire depuis 1,5 mois, le 3è étant sous CLIN seule depuis 10j. Résultats: Le patient en monothérapie au 5FU rechute au bout d'1 mois; l' IRM du 2è est à 2 mois normale en dehors d'une encéphalite VIH, pour le 3è la CLIN est arrêtée à J10 (toxidermie sévère) l'IRM à 1 mois montrant une disparition de l'oedème avec un abcès stable en taille mais moins évolutif. La tolérance biologique est parfaite pour les 3 pts et pour les 2 derniers l'amélioration clinique est spectaculaire. Discussion: L'activité anti-toxoplasmique de l'association 5FU-CLIN n'a jamais été démontrée; cependant sur la base d'études in vitro ce traitement a été tenté chez 3 pts en impasse thérapeutique. Les résultats partiels obtenus appellent 3 remarques : la méconnaissance de la pharmacocinétique du 5FU à cette faible posologie (passage neurologique, modalité de perfusion), la responsabilité de la CLIN dans l' efficacité de l'association, enfin le recul insuffisant sur ce petit nombre de patients. Conclusion: L'association 5FU-CLIN peut être intéressante en cas d'impasse thérapeutique de la TC du SIDA: une évaluation préalable in vitro et chez l'animal paraît souhaitable.

M.B.O.37 CENTRAL NERVOUS SYSTEM TOXOPLASMOSIS IN AIDS PATIENTS. EFFICACY OF AN INTERMITTENT MAINTENANCE THERAPY

Pedrol E, González-Clemente JM, Josep M. Gatell, Mallolas J, Miró JM, Soriano E. Infectious Diseases Unit. Hospital Clinic. University of Barcelona. Barcelona. Spain.

OBJECTIVE. To describe the characteristics of 34 episodes of Central Nervous System (CNS) toxoplasmosis and the efficacy of an intermittent (2 days per week) maintenance therapy to avoid relapses.
METHODS. CNS toxoplasmosis was accepted when the clinical and CT scan findings were consistent unless an alternative diagnosis became apparent. Treatment was performed with pyrimetamine (P) (25 mg) plus sulfadiazine (S) (100 mg/kg) or clindamycin (C) (2400 mg) daily during 3 weeks. Same drugs and dosage were used for maintenance therapy but given only 2 days per week.
RESULTS. Thirty four episodes of CNS toxoplasmosis developed in 29 (15.1 %) of the 192 AIDS cases diagnosed during a 24 months period. Twenty (69%) were drug addicts and the toxoplasmosis was the first opportunistic infection in 15. Focal neurological signs (64.7%) were the most common clinical presentation and ring-like contrast enhancing lesions (55.9%) the most common CT scan finding. A basal IgG antitoxoplasmic antibody titer) 1/20 was found in all cases. Twenty four patients (82.8%) survived the first episode and could be followed-up. Three (27.3%) among the 11 who decided not to perform any maintenance therapy relapsed. Conversely none of 13 with an intermittent maintenance therapy (11 with P/S and 2 with P/C) relapsed, during a median follow-up of 6 months.
CONCLUSION. CNS toxoplasmosis is a frequent opportunistic infection in Spanish AIDS patients and an intermittent long term maintenance treatment with P/S or even with P/C was effective for preventing relapses.

M.B.O.38 MORTALITY, TREATMENT RESULTS AND RELAPSE RATES OF PULMONARY TUBERCULOSIS IN AFRICAN HIV(+) AND HIV(-) PATIENTS

Perriëns, Joseph *; Karahunga, C. *; Willame, J.C. **; Kaboto, M.***; Pauwels, P. **; Colebunders, R. *.
*Projet SIDA, **Bureau National de la Tuberculose, ***Centre de Depistage de la Tuberculose, Kinshasa, Zaire.

Objectives. To assess mortality, efficacy of anti-tuberculous(TB) therapy, and relapse rate of pulmonary tuberculosis (pTB) among HIV(+) and HIV(-) patients in Kinshasa, Zaire.
Methods. We tried to trace 754 smear (+) pTB patients who participated in in a 1987 crossectional HIV seroprevalence study among TB in- and outpatients. Patient records were reviewed to assess mortality. All survivors were invited to participate in a prospective study. After completing 1 year anti-TB treatment patients were evaluated by clinical exam, sputum Ziehl smear, TB culture, HIV serology and chest X-ray, and later, bimonthly by sputum smear.
Results. Mortality: data were available from 631 (84%) patient records. Sixty (38%) of 155 HIV(+) and 26 (5.5%) of 476 HIV(-) patients had died within 12 months after TB diagnosis (p(0.0001).
Treatment results: 349 (46%) patients were evaluated after completing TB treatment. Eleven (14%) of 79 HIV(+) and 39 (14%) of 270 HIV(-) patients had a (+) TB culture (all M.tuberculosis). Eight (73%) of 11 HIV(+) and 32 (82%) of 39 HIV(-) TB culture (+) patients had (-) sputum smears. Relapse rate: 5 (7%) of 68 HIV(+) and 23 (10%) of 231 HIV(-) patients had a smear (+) pTB relapse within 6 months after stopping anti-TB drugs.
Conclusion. In this study surviving HIV(+) patients responded equally as well to anti-TB treatment as HIV(-) patients, but HIV (+) patients had higher mortality rates. Surviving HIV(+) pTB patients were not at increased risk of pTB relapse.

Pédiatrie : développement neurologique des enfants infectés par le VIH
Pediatric: Neuro-Development in HIV Infected Children

M.B.0.39

NEUROLOGICAL INVOLVEMENT AND PRONOSTIC FACTORS AFTER MATERNO-FETAL INFECTION

M. TARDIEU, S. BLANCHE, A.M. DULIEGE, C. ROUZIOUX, C. GRISCELLI
INSERM U 56, 132, 292, Paris FRANCE.

Ninety four HIV1-infected infants (present median age 3 years) have been serially followed : 20 % of patients had intense, and 6 % moderate neurological abnormalities (onset during the first year for 60 % of patients). Intense neurological abnormalities were correlated with an increased risk of death (relative risk : 8, survival rates at 3 years 30 % vs 94 % in other patients), with the presence of opportunistic infections and, at initial evaluation, with presence of a low lymphocytic proliferation rate to antigen stimulation, a low T4 count, with the absence of anti P18 and P25 antibodies in serum. A low or negative titer of anti HIV antibodies in CSF was also correlated with intense neurological disease. Conversely, an intra blood brain barrier anti HIV antibodies synthesis was observed in all tested patients without neurological disease. Abnormalities in CT scan were found in 37,5 % of patients with neurological disease, usually late during the course of the disease.

In conclusion : (1) The evolution of HIV infected infants was bimodal, one groupe having a poor prognosis and a severe encephalopathy and the other a better prognosis and no frank encephalopathy (although an intermediate degree of mental retardation might be frequent) ; (2) intensity of neurological disease and immunodeficiency were highly correlated.

M.B.0.40

A PROSPECTIVE STUDY OF NEUROLOGICAL DEVELOPMENT IN INFANTS AT RISK FOR HUMAN IMMUNODEFICIENCY VIRUS (HIV-1) INFECTION.

Scott, Gwendolyn, Cohen, D., Maguiat, A., Curless, R., Morgan, R., and Parks, W. University of Miami School of Medicine, Miami, Florida.

Objective: To prospectively determine the nature and prevalence of neurological and developmental abnormalities in infants of HIV-1 infected women. Methods: Sixty infants of HIV-1 seropositive women and 8 uninfected controls were evaluated every 3 months for neurological and developmental (using the Bayley Scale) abnormalities. Results: The mean enrollment age of subjects was 3 months (range 2-26 months). Of the infants born to seropositive women there were 15 HIV-1 infected infants, 9 uninfected infants and 36 infants of indeterminant status. Statistically significant differences were found in the frequency of abnormal neurological findings and below average Bayley scores, ($p<0.01$ and $p<0.05$, respectively; Fisher's exact test), when the study groups were compared with each other and with controls. Nine of the 15 HIV-1 infected infants had abnormal neurological examinations and 7 had Bayley Scales between 1 to 3 SD below normal. Neurologic findings included hypertonia (6), hyperreflexia (5), truncal hypotonia (4) and acquired microcephaly (4). Of the 7 known HIV-1 infected children with normal neurological examinations none had abnormal Bayley Scales. Six of 7 uninfected infants born to seropositive mothers had normal neurologic and developmental exams. Conclusions: Neurological abnormalities were detectable in the first year of life in 60% of known HIV-1 infected infants. Further study of this group is needed to determine whether all children ultimately develop abnormalities.

M.B.0.41

THE COURSE OF NEURODEVELOPMENTAL FUNCTIONING IN THE INFANTS OF IVDA AND HIV SEROPOSITIVE PARENTS

Nozyce, Molly*; Diamond,G.*; Belman,A.**; Cabot,T.; Cohen,H.* and Rubinstein,A.; et.al. Albert Einstein College of Medicine, Dept. of Pediatrics, Bronx, New York, *Rose F. Kennedy Center, **SUNY, Stonybrook, USA

Objective. To study the medical and neurodevelopmental effects of various teratogens on the offspring of high risk and substance abusing parents.
Methods. Pregnant women with both high risk and substance abusing behaviors who attended hospital affiliated clinics were offered enrollment in a multicenter NIH sponsored program. A cohort of 34 infants born to these mothers were followed longitudinally during the first year of life with serial standardized developmental evaluations and medical and neurological assessments. Thirty-two percent of the mothers were seropositive for HIV. A Kent State Adaptation was performed on the Bayley Scales of Infant Development in order to delineate strengths and weaknesses in different areas of functioning.
Results. Early results during the first year of life indicate that the general rate of development is slower in the HIV positive group compared with the non-infected group. Prelinguistic language skills were more delayed than other areas of functioning (chi square significant at the $<.05$ level). Among the seropositive infants, no regression in developmental skills was noted except during periods of acute illness. Subjects were matched and no significant differences were found in social support, level of maternal education and parity.
Conclusions. Current data indicates that subtle central nervous system(CNS) impairments may be more pervasive earlier than previously documented in HIV seropositive infants and they differ from patterns in older children.

M.B.0.42

PROSPECTIVE NEURODEVELOPMENTAL OUTCOME OF INFANTS WITH PERINATALLY ACQUIRED HIV INFECTION AND THEIR CONTROLS.

Hittelman,Joan*;Willoughby,A.**;Mendez,H.*;Kehe,J.*;Goedert,J.**; Landesman,S.*;et al. SUNY-HSC Brooklyn,NY,USA;**NIH,Bethesda,Maryland,USA

OBJECTIVE. To assess the neurodevelopmental sequelae of HIV infection in children.
METHOD. As part of a prospective neurodevelopmental follow-up, 47 children born to HIV seropositive mothers and 71 born to seronegative controls were evaluated at 1,3,6,9,12 and 18 months of age using age appropriate instruments (Einstein and Bayley Scales, and the Fagan Test of Visual Memory), by an examiner blind to the infants' serostatus.
RESULTS. Of the infants born to seropositive mothers, 10 were clinically infected; 17 seroreverted by 15 months of age and 20 were of indeterminate status. No differences in development were found when comparing the infants of HIV infected mothers with those of the seronegative mothers. Of the 10 HIV infected infants, 9 had HIV disease. Eight of the 9 had motor disabilities, 6 of whom presented with mental retardation. Three showed progressive deterioration. At every age, infected infants had more delays than did the controls. Eight of the 10 HIV infected infants had developmental delays before 18 months of age, in contrast to disability rates of 5% in the seronegative controls ($p<.01$) and 18% in seroreverters ($p<.05$). The disability rate of infants who had seroreverted did not differ from the controls.
CONCLUSION. The data demonstrate a strong relationship between perinatally acquired HIV infection and neurodevelopmental disability.

M.B.0.43

THE ADAPTIVE BEHAVIOR OF CHILDREN WITH SYMPTOMATIC HIV INFECTION AND THE EFFECTS OF AZT THERAPY.

Wolters, Pamela, Moss, H., Eddy, J., Pizzo, P., Brouwers, P.. Pediatric Branch, National Cancer Institute, NIH, Bethesda, MD USA

Encephalopathy, manifested by neuropsychological deficits and loss of developmental milestones, is a major concomitant of pediatric AIDS. Although there have been subjective descriptions of behavioral changes observed in HIV infected children, the effect of encephalopathy on the everyday behavioral functioning in these children has not been measured. Therefore, the social and personal behavior of children with symptomatic HIV infection was assessed before and after AZT treatment to determine the impact of anti-retroviral therapy on the adaptive behavior in a pediatric AIDS population.

Twenty-three children with AIDS, participating in protocols at the NCI Pediatric Branch to evaluate the efficacy of AZT, received drug therapy for six months. At baseline the children ranged from one to twelve years of age (mean age = 5.9 years). Eleven patients were categorized as encephalopathic according to loss of developmental milestones and positive head CT scan findings prior to starting AZT.

Adaptive behavior was assessed before and after treatment with the Vineland Adaptive Behavior Scale, a semi-structured interview administered to the child's parent or primary caregiver. This scale yields standardized scores in four domains: communication, daily living, socialization, and motor skills, and an overall index of adaptive functioning. Each area is further divided into subdomains.

Pretreatment measures indicated that the adaptive functioning of encephalopathic children was in the mildly deficient range and significantly lower in all domains and subdomains than the clinically non-encephalopathic children who performed in the average to low average range. More specifically, children with encephalopathy were significantly more impaired in their expressive as compared to receptive language; in contrast, the non-encephalopathic children exhibited comparatively higher expressive skills. After six months of AZT therapy, significant improvements were observed for both groups in communication (receptive and expressive language), daily living (personal care and community skills), socialization (interpersonal and play skills), and overall adaptive behavior. However, there were no significant changes in fine and gross motor skills. Several domains of adaptive behavior were found to significantly correlate with IQ scores, behavioral ratings, and some hematological measures particularly at baseline. These results specifically demonstrate the profound effect that encephalopathy has on the everyday functioning of children with symptomatic HIV infection and suggests that AZT therapy can have a positive impact on behavior.

M.B.0.44

Neurologic Disease in Pediatric HIV Infection:

Kairam, Ram; Kaul, A; Bamji, M; Gupta, A; Bakshi, S; Pitt, J. St. Luke's-Roosevelt Hospital Center, Columbia University Presbyterian Medical Center and New York Medical College, NY, USA

Objective: To describe the spectrum of neurologic disease in Pediatric HIV infection and follow the course of direct injury to the nervous system.
Methods: 130 children were seen over a period of 5 years by a single child neurologist, utilizing a standard neurologic examination, CAT scans of the brain, spinal fluid evaluation and Somatosensory Evoked potentials (SEP).
Results: Progressive encephalopathy marked initially by language abnormalities, and hypotonia progressing to spastic tetraparesis and acquired microcephaly was common. Children exhibiting static encephalopathy initially exhibited progressive signs with longer follow-up. Five children exhibited improvement in enhanced environment. Seizures were uncommon. CAT scan findings were prognostic of outcome. SEP studies revealed striking abnormalities in subcortical structures. EEG studies and spinal fluid evaluations were not helpful.
CONCLUSIONS: HIV produces a wide spectrum of neurologic involvement with a variable, but usually progressive course. Neurologic involvement is seen in nearly 90% of infected children.

Traitement : essais de l'AZT
Therapy: AZT Trials

M.B.0.45 VALIDATION OF THE SURVIVAL EXPERIENCE AMONG A LARGE COHORT OF AIDS PATIENTS TREATED WITH ZIDOVUDINE

Creagh-Kirk,Terri; Doi,P.; Andrews, E. and Tilson, H.
Burroughs Wellcome Co., Research Triangle Park, North Carolina, U. S. A.

Objective. To validate and extend the original survival experince reported in a large cohort of AIDS patients who received zidovudine through a compassionate-release program.
Methods. Through a compassionate-release system, 4805 AIDS patients began treatment with zidovudine over a six-month period in late 1986 and early 1987. These patients were also closely monitored for an additional 5 months by means of a structured epidemiologic study and data from a limited drug distribution system. Survival experience up to 44 weeks after treatment initiation has been published. However, because the loss-to-followup rate in the original population was high, an effort was made to validate actual survival in a subcohort of all patients treated in sites participating in another study where retrospective data collection provided nearly complete followup.
Results. The validation study confirmed the original survival experience reported and extended that experience beyond 12 months. Prognostic effects of baseline hemoglobin level and functional status as well as the elapsed time between diagnosis and treatment were examined.
Conclusion. A validation study has confirmed previous findings and allowed assessment of survival beyond that reported previously for a subset of patients. The extent to which these data can be generalized to the original population will be discussed.

M.B.0.46 SURVIVAL PATTERNS OF ZIDOVUDINE TREATED AIDS PATIENTS COMPARED TO UNTREATED CONTROLS.

Vella, Stefano; Menniti Ippolito, F.; Agresti, M.G.; Pezzotti, P. and Greco D.
National Institute of Health, Rome, Italy.

Objective. In order to establish the influence of antiviral therapy on survival of AIDS patients, we compared survival patterns of patients receiving zidovudine with survival patterns of a control group of patients who were contemporaneously not receiving ZDV.
Methods. All italian adult AIDS cases reported between January '87 and March '88 were included in this study. Of those, 272 began ZDV therapy between August '87 and May '88 and have been treated for more than 30 days, while 773 remained untreated till July '88, most of them because of organization problems. Age, gender and risk factor (77% I.V. drug abusers) distributions were similar in the two groups. Survival was calculated for each patient from the date of diagnosis through July 31, '88, by Kaplan-Meier method . Wilcoxon test was used to evaluate differences between curves.
Results. Survival at 12 months for treated patients was 90.9% (SE=2.48) while survival of untreated patients was 44.4% (SE=2.28) ($p<0.0001$). Survival pattern of patients who initiated therapy but voluntarily interrupted within 30 days approached the survival of untreated patients (55.3%). Stratification for clinical presentation and semester of diagnosis, and geographical location of clinical centers didn't significantly affect the differences in survival of the two groups of patients.
Conclusions. Data obtained clearly confirm that ZDV therapy is associated with increased survival of AIDS patients, also when comparison is made with untreated controls and not simply with historical controls.

M.B.0.47 NATURE, TIME COURSE AND DOSE DEPENDENCY OF ZIDOVUDINE RELATED SIDE EFFECTS. RESULTS FROM THE MULTICENTRE CANADIAN AZIDOTHYMIDINE TRIAL (MCAT).*

Ruedy, John; Montaner, JSG; Gelmon, K; Fanning, M; Smith, JRM; Falutz, J; Tsoukas, C; Gill, J; Wells, G; O'Shaughnessy, M and Wainberg, M. Multicentre Canadian Azidothymidine Trial (MCAT). Canada

OBJECTIVE. To characterize the nature, time course and dose dependency of zidovudine related side effects in early HIV-infected individuals.
METHODS. DESIGN: Multicentre prospective, dose range finding study. SUBJECTS: 74 HIV positive homosexual men belonging to CDC groups II, III and IVC2. INTERVENTION: Following a 3 week observation period, volunteers were treated with zidovudine 600 mg/day for 18 weeks, 900 mg/day for 9 weeks and 1200 mg/day for 9 weeks followed by a washout period of 6 weeks after which they were re-started on 1200 mg/day or the highest previously tolerated dose at q8h intervals. Subjects were randomly assigned to q4 or q8h regimens within CDC groups while initially taking 600 and 1200 mg/day. FOLLOW-UP: Clinical and laboratory evaluations were performed at 3 week intervals.
RESULTS. Symptomatic adverse effects were present in 96% of subjects, most commonly nausea (64%), fatigue (55%) and headache (49%). These were generally self-limited, reappearing briefly at each dose increment. A decrease in hemoglobin occurred shortly after initiation of therapy. This was not dose dependent and reversed rapidly upon discontinuation of treatment. A red blood cell count decrease, a mean cell volume increase and a granulocyte count decrease developed early in a dose independent fashion, reverting at least partially during the washout phase. The decrease in reticulocyte count was dose related between 600 and 900 mg/day with no further change when the dose was escalated to 1200 mg/day. Bone marrow changes occurred rapidly as demonstrated by megaloblastosis in 95% of 65 specimens at week 18. LDH remained unchanged through out the 60 weeks. These effects were not dependent on study site, CDC group or drug regimen (q4h vs q8h).
CONCLUSION. Zidovudine related hematological effects include a mild macrocytic megaloblastoid anemia with a decrease in reticulocyte count and granulocytopenia. These appear to be dose independent in the range 600 mg to 1200 mg/day and rapidly reversible upon discontinuation of the drug. The fact that these effects are maximal on the smallest dose employed (600 mg), supports the need for efficacy studies at lower doses than those currently recommended.

* Supported by a grant from National Health Research Development Programme (NHRDP), Health & Welfare, Canada.

M.B.0.48 DOUBLE-BLIND PLACEBO CONTROLLED STUDY OF RECOMBINANT HUMAN ERYTHROPOIETIN IN AIDS PATIENTS WITH ANEMIA CAUSED BY HIV INFECTION AND ZIDOVUDINE.

Karick Mark; Wilson E, Bernstein-Singer M, Gill PS, Muggia F, Levine AM.
Univer. of Southern California School of Medicine, Los Angeles, CA, USA.

Objective: To assess the efficacy and toxicity of recombinant Human Erythropoietin (re-HuEPO) in AIDS patients (pts) with anemia while receiving Zidovudine (AZT).
Methods: Pts treated at our institution who were entered into a multi-institutional placebo controlled study of re-HuEPO in AIDS pts with anemia while receiving AZT are described. Pts were included if their Hematocrit was <30%, they were transfusion dependent, or had a 15% or greater drop in their Hmt while on AZT. Pts were randomly assigned to re-HuEPO (Ortho Pharm.) 100U/kg SQ tiw or placebo [P (Human albumin)] for 12 wks. An open label (OL) period of 24 wks followed, with dose escalation not to exceed 900U/kg/wk. Baseline EPO levels, weekly CBC, reticulocyte count, and blood transfusion (bld trf) requirement were recorded.
Results: 7 pts have been enrolled in the study. Baseline median Hgb level was 10.5gm/dl (range 8.9-11.8). Median bld trf units were: baseline 3, range (2-11), P controlled period 3, range (0-6), and during OL period 0 range (0-6). 4 of 7 (57%) received no bld trf during the OL period. Two of 7 (29%) continued to require frequent blood transfusions during the OL period. Comparison of baseline EPO levels, dose of AZT, in relation to response to re-HuEPO will be presented. No adverse effects were seen.
Conclusions: 1) The use of re-HuEPO in AIDS pts is safe; 2) re-EPO can decrease the bld trf required of a select group of AIDS pts while on AZT; 3) Response may inversely correlate with endogenous EPO production.

M.B.0.49 TOXICITY OF COMBINED AZT/GANCICLOVIR (DHPG) THERAPY IN AIDS PATIENTS

Nussbaum, Joseph; Antoniskis, D; Causey, D; Leedom, JM.
LA Co-USC Medical Center, Los Angeles, California, USA.

Objective: To assess the incidence of serious hematologic toxicity during combined AZT/DHPG therapy (Rx). Methods: 26 patients (pts) were treated with combined Rx from Jan 1986 to Dec 1988. No cytokines were used. DHPG maintenance was 5mg/kg/d x7d/wk in 17/26 pts, x5d/wk in 9/26. Toxicity strategy: for NIH grade 3 (gr3) granulocytopenia, 50% AZT 100% DHPG dose; for gr4 granulocytopenia, 0% AZT 0% DHPG; anemia, transfusion only. AZT and DHPG doses were escalated as soon as granulocytes >500.
Results: Average duration of combined Rx was 12.1 wks/pt (range 4-30wks/pt). AZT dose = 1200mg/d for 48% of wks of Rx, 600mg/d for 26% and <600mg/d for 26%. One episode of gr4 granulocytopenia was associated with gram-negative bacteremia. No serious bleeding was observed during Rx.

	GRANULOCYTOPENIA		THROMBOCYTOPENIA			ANEMIA
#episodes	gr3(500-749)	gr4(<500)	gr2(50-74K)	gr3(25-49K)	gr4(<25K)	<6.5G/Hb
total	30	19	2	5	1	10
per pt	1.2	0.7	--	--	--	av. 2.4u/pt transfused
range	1-4	0-4	0-1	0-1	0-1	0-9u/pt

Conclusions: Despite previous reports, prolonged combined AZT/DHPG Rx is possible. Temporarily lowered doses of AZT may be required by hematologic toxicity. Patients should not be denied the benefits of anti-retroviral therapy as toxicity is tolerable.

M.B.0.50 ONE YEAR FOLLOW-UP OF ZIDOVUDINE PLUS ACYCLOVIR IN ASYMPTOMATIC HIV-SEROPOSITIVES

Hollander, H.*; Moore, M.**; Nusinoff-Lehrmann, S.**; Barnhart, J.***; Lifson, A.***. *University of California, San Francisco, CA, **Burroughs-Wellcome Company, Research Triangle Park, NC, ***AIDS Office, Department of Public Health, San Francisco, CA, U.S.A.

Objective. To study the tolerance, toxicity and immunologic effects of zidovudine (ZDV) plus acyclovir (ACV) in asymptomatic HIV-seropositives.
Methods. Twenty gay men in CDC group II were given ZDV (500 mg/day) plus ACV (2 or 4 grams/day) and followed with frequent clinical and laboratory monitoring.
Results. At week 52, 16 men remained well and in the study. Three had withdrawn because of subjective toxicities of the drugs; 1 was diagnosed with non-Hodgkin's lymphoma at week 7. Two men required permanent dose reduction because of side effects. Hematologic changes noted were a decrease in mean red blood count (5.03 to 4.04, $p=0.0001$) and an increase in mean corpuscular volume (87.3 to 105.4, $p=0.0001$). Hemoglobin, neutrophil count and platelets were unchanged. Changes in mean LDH (165 to 219 U) and total bilirubin (0.65 to 0.91 mg/dl) were significant; mean creatine kinase rose from 148 to 203 U, but this was not significant ($p=0.20$). Total lymphocyte counts were unchanged; total mean CD4 lymphocytes were 512 at entry and 580 at week 52. ($p=0.33$).
Conclusion. ZDV and ACV at these doses are tolerated by the majority of asymptomatic HIV-seropositives for at least one year. Immunologic stability as measured by total CD4 count is encouraging, but efficacy in preventing disease progression is unproven and awaits the results of controlled trials.

Prophylaxie de la PCP
PCP Prophylaxis

T.B.0.1

FOLLOW-UP STUDY OF PATIENTS RECEIVING PENTAMIDINE AEROSOL FOR PROPHYLAXIS OF PCP

Scolaro, Michael J.*; Kennedy, P.*; Kahn, B.**; Magee, T.* and Eggerding, F.*
*Los Angeles Oncologic Institute, St. Vincent Medical Center, Los Angeles, California 90057, **Chief, Pulmonary Medicine, St. Vincent Medical Center, Los Angeles, California 90057, U.S.A.

Objective. To evaluate the efficacy of inhaled pentamidine in prevention of PCP during a 6 to 18 month follow-up period.
Methods. 51 patients with HIV (ARC/AIDS) have been maintained on pentamidine, 150 mg every two weeks by inhalation. Group One: 17 patients with prior PCP and with mean T4 of 106 cells/cu mm. Group Two: 34 patients with ARC/AIDS without history of PCP and mean T4 of 262 cells/cu mm. All patients received AZT and acyclovir.
Results. Incidence of drug toxicity, PCP, and death was compared.

Patient Group	Toxicity	PCP or Recurrent PCP	No. of Deaths
I (N=17)	0	2	6
II (N=34)	0	0	0

The 6 deaths in I were unrelated to PCP.
Conclusion. Aerosolized pentamidine is effective prophylaxis against pulmonary Pneumocystis carinii in HIV immunosuppressed patients.

T.B.0.2

EFFETS DES AEROSOLS PROPHYLACTIQUES DE PENTAMIDINE SUR LA FONCTION RESPIRATOIRE A MOYEN TERME

Camus, Françoise ; de Picciotto, C., Leprêtre, A., Landman, R., Girard, P.M., Saimot, A.G.
Hôpital Bichat-Claude Bernard,Paris,France.

Objectif. Evaluer la tolérance pulmonaire des aérosols de Pentamidine (APM) par la mesure de la capacité de transfert à l'oxyde de carbone (TLCO) et du gradient alvéolo-artériel en oxygène Δ (A-a)O2.
Méthodes. 46 patients SIDA ont été suivis pendant au moins neuf mois à la suite d'1 (ou 2) épisode (s) de pneumocystose (Mo).
Groupe contrôle (n = 10) ; groupe APM (n = 36) : APM 1 fois/mois.
La TLCO à l'état stable (% de la valeur théorique) et Δ (A-a)O2 (torrs) ont été mesurés à : M1 et M7 (1 et 7 mois après la pneumocystose). Aucun des 46 patients inclus dans cette étude n'a présenté de rechute de pneumocystose avant M9.
Résultats.

	M1		M7	
	TLCO %	Δ(A-a)O2 t	TLCO %	Δ(A-a)O2 t
Groupe contrôle	58,5 ± 14,1	22,8 ± 14,4	67,1 ± 16,9	30,2 ± 17,7
Groupe AMP	66,5 ± 15,6	14,1 ± 11,7	72,7 ± 16,5	15,4 ± 11,9

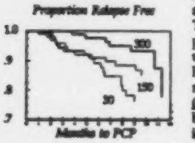
La TLCO augmente de façon non significative dans les deux groupes. Δ (A-a)O2 reste stable dans le groupe APM et augmente de façon non significative dans le groupe contrôle.
Conclusion. Les aérosols de Pentamidine ne semblent pas entrainer de troubles fonctionnels respiratoires dans la limite de la durée de cette étude.

T.B.0.3

AEROSOL PENTAMIDINE FOR *PNEUMOCYSTIS CARINII* PNEUMONIA PROPHYLAXIS: A 3 ARM RANDOMIZED TRIAL.

Leoung, Gifford S*; Montgomery, A.B**; Abrams,D.I*; Wardlaw, L*; Corkery, K*; Busch, D.***; Gordon, S.****; Feigal, D.W.*; and the SF County Community Consortium.
* Department of Medicine, San Francisco General Hospital, Univ. of California, SF; ** SUNY at Stonybrook, NY; *** Childrens Hospital, SF; **** Pacific Presbyterian Medical Center, SF.

Objective: To determine the efficacy of aerosol pentamidine for prophylaxis against *Pneumocystis carinii* pneumonia (PCP) in high risk HIV infected patients.
Methods: 408 patients were randomized to treatment with either 30mg q2w, 150mg q2w or 300mg q4w of aerosol pentam (AP) stratified into groups: prior PCP (PCP, n=256); Kaposi's Sarcoma (KS, n=56); or ARC and other AIDS diagnoses (OT, n=116). AP was delivered with a Marquest Respigard II nebulizer (particle MMAD=1.42 microns).
Results: Mean follow up in ongoing patients was 301 days (range 190-347). Intention to treat (ITT) analysis and analysis of PCP events of PT on study (OS) i.e. 28 days of eligibility and <60 days after last Rx showed 63 and 48 events (17% and 13%), respectively. Only 9 PCP events occurred in the KS or OT strata; 75% of all PCP events were histologically confirmed. The log-rank statistics comparing the three arms (ITT) were: p=.006 for 30 vs. 300, p=.19 for 30 vs. 150, and p=.17 for 150 vs. 300. Cox regression models to adjust for number of prior PCP episodes, time since last PCP and zidovudine use. The reduction in relative hazard (300 vs. 30) was 2.1 fold (p=.01).
Conclusion: There is a dose response showing 300mg q4w is best despite the longer interval between treatment. Since this is a dose response study, it underestimates the benefits of AP compared to no treatment.



T.B.0.4

SUCCESSFUL CHEMOPROPHYLAXIS FOR PNEUMOCYSTIS WITH DAPSONE OR BACTRIM

Metroka, Craig E.*; Jacobus, D.**; Lewis, N.**.
St. Luke's/Roosevelt Hospital Center, New York, N.Y., USA, **Jacobus Pharmaceutical, Princeton, N.J.,USA

Objective. An open study of the efficacy and tolerance of dapsone or bactrim in the prevention of pneumocystis (PCP).
Methods. We studied 221 patients (pts) who were at high risk for PCP from 4/85 to 6/88 and received prophylaxis. All pts had either <250 T4+ cells/mm3, severe constitutional symptoms (17 pts), or a prior opportunistic infection (OI).
Results. The mean T4+ cells at the time of treatment initiation was 142 (range, 9 to 573). 173 pts received dapsone (avg 9.4 mos, range up to 43 mos) and 48 pts received bactrim (avg 8.2 mos, range up to 57 mos). 2/173 pts receiving dapsone 25 mg qid and 0/48 pts receiving bactrim ds 1 tab bid developed PCP (p=0.37, NS). In contrast, 26 episodes of PCP occurred in 23 pts who refused prophylaxis (avg 9.6 mos, range up to 29 mos). 10% of pts receiving dapsone and 38% of pts receiving bactrim prophylaxis experienced an adverse reaction (p<0.0001). Pts hypersensitive to 1 drug generally tolerated the other. 1/29 pts receiving both dapsone and AZT had to be withdrawn from dapsone because of a sustained drop in Hct. 15 pts developed Kaposi's Sarcoma while receiving dapsone. No pts receiving dapsone developed cryptosporidiosis. 125 pts receiving dapsone and 20 pts receiving bactrim developed other OI or malignancies; 89 pts on dapsone and 8 pts on bactrim have died.
Conclusions. Both dapsone and bactrim are equally effective in preventing PCP but a higher percentage of pts receiving bactrim experienced adverse reactions.

T.B.0.5

LOW DOSE DAPSONE (D) PROPHYLAXIS (PX) OF PNEUMOCYSTIS CARINII PNEUMONIA (PCP).

Lang, Onnie S., Kessinger, J.M., Tucker, R.M., Greene, S.I., Deresinski, S.C. and Stevens, D.A.
Santa Clara Valley Medical Center, San Jose, CA, USA.

Objective. We evaluated the safety, efficacy and cost effectiveness of D as PX of PCP.
Methods. D (50-100 mg/d) was given as oral PX of PCP to 24 patients (PTS) with AIDS (21 PTS) or ARC (3 PTS). All PTS were male; mean age was 36.3 yrs.; mean duration of disease was 9.7 mos. Three PTS received D as 1^{o} PX and 21 as 2^{o} PX; the maximal daily dose was 100 mg in 10 and 50 mg in 14.
Results. Mean duration of PX is 108 d (range: 21-450 d). There are 88 total patient mos. of PX: 71 on 50 mg/d, 17 on 100 mg/d; 17 PTS (71%) remain on PX, 4 are alive off PX and 3 have died (none of PCP). One PT relapsed with mild PCP on PX after 4 wks. of D (50 mg/d), was treated successfully with D and trimethoprim and remains well on D (100mg/d). Suspected toxicity occurred in 5 PTS (rash in 3); D was stopped in 4/5; none had serious sequelae. Monthly cost of PX per PT at our institution is $1.43 for 50 mg/d of D, $2.85 for 100 mg/d and ~$400.00 for inhaled pentamidine (4mg/kg every 14d).
Conclusion. D (50-100 mg/d) is inexpensive and well tolerated. Our results suggest that even 50 mg/d is effective PX of PCP in AIDS. Comparative trials with alternative PX agents and dose finding studies of D for PX of PCP are in order.

T.B.0.6

TRIMETHOPRIM-SULFAMETHOXAZOLE FOR SECONDARY PROPHYLAXIS OF PNEUMOCYSTIS CARINII PNEUMONIA IN AIDS

Pierone, Gerald; Masci, J., Nicholas, P.
Mt. Sinai Services, Elmhurst Hospital Center, Elmhurst, N.Y. U.S.A.

Objective. To determine if maintenance therapy with trimethoprim-sulfamethoxazole (TS) prevents recurrent infection with Pneumocystis carinii pneumonia (PCP) in patients with the acquired immunodeficiency syndrome.
Methods. Records were reviewed on all patients who had received at least 3 months of therapy with zidovudine (ZD) following an initial episode of PCP.
Results. 23 patients were identified. 12 of these patients also received TS in a dose of one double-strength tablet BID (group 1). 11 patients were not treated with TS or any form of prophylaxis for PCP (group 2), 10 because of previous adverse reactions. The two groups were comparable with regard to the severity of PCP (A-a gradient of 44.8 and 46.3 respectively) and time interval between diagnosis of PCP and initiation of ZD (1.7 vs. 1.8 months respectively). None of the patients in group 1 developed PCP during 101 patient-months of follow-up (mean 8.4 months). In group 2, there were eight episodes of PCP, three fatal, during 90 patient-months of follow-up (mean 8.2 months) ($p<0.001$). The one year mortality was 1/12 (8%) in group 1 and 4/11 (36%) in group 2 ($p<0.05$). ZD dosage was reduced in 2/12 patients in group 1 because of neutropenia and 4/11 patients in group 2 secondary to anemia. This difference was not significant.
Conclusion. TS is effective in the secondary prophylaxis of PCP in patients being treated with ZD, improves survival, and is not associated with increased bone marrow toxicity.

Le SIDA dans les pays en voie de développement
AIDS in the Developing World

T.B.0.7

EVALUATION OF DEFINITIONS FOR AIDS CASE SURVEILLANCE

Rodrigues, LGM*; Morais de Sá, CA**; Ramos Filho, Celso F***; Weniger, BG****; Sereno, AB*** Krebs, JW****; Quinhoes, EP**; Ismael, C**; Chequer, P*; and the Clinical AIDS Study Group.
*Ministry of Health (MH), Brazil; **Hosp Gaffrée e Guinle, Univ do Rio de Janeiro (RJ); ***Hosp Universitário, Univ Fed do RJ, Brazil; ****Centers for Disease Control, Atlanta, USA.

Objective. To measure and compare the sensitivity and specificity of 3 surveillance case definitions for AIDS currently recommended for Brazil (MH), for the USA (CDC), and for Africa (WHO) on a large group of hospitalized patients in Rio de Janeiro, Brazil.
Methods. Medical history, physical exam, and chart review were done on 245 non-surgical inpatients (vide Sereno, AB, *et al*) to determine whether they met the MH, CDC, or WHO criteria for AIDS. The "gold standard" was defined as a repeatedly-reactive ELISA test to either HIV-1 or HIV-2 with Western blot bands representing ≥2 gene regions of the corresponding virus. There were 110 HIV+'s and 135 HIV-'s in the study. Weighted analysis adjusted for the random sampling used to select HIV-'s. Overall HIV+ prevalence was 24%.
Results. The sensitivities of the MH, CDC, and WHO definitions were 50%, 52%, and 59%, respectively. Specificities were 99%, 99%, and 96%. PVPs: 96%, 96%, 89%. PVNs: 86%, 86%, 88%. Only 3 cases of *Pneumocystis* pneumonia (PCP) and 4 of cerebral toxoplasmosis (CT) were lab confirmed. Nine (29%) of 31 patients diagnosed with PCP, and 12 (43%) of 28 with CT met neither the clinical nor lab criteria of the MH.
Conclusions. Current AIDS definitions have poor sensitivity when laboratory confirmation of AIDS-related diseases is impractical. Although improved clinical/serological definitions for AIDS may not help clinicians diagnose specific opportunistic diseases, they may prompt earlier suspicion of HIV infection. Revision of the MH AIDS definition is planned in 1989, based on empirical data generated in a related study (vide Perez, MA, *et al*).

T.B.0.8

HIV-1 AND HIV-2 INFECTION PREVALENCE IN THE MORTUARY-ABIDJAN

Gnaore, Emmanuel*; De Cock, K.*; Diaby, L.*; Porter, A.*; Dago, A.**; and Lafontant, G.**; et al.
*Projet RETRO-CI; **University of Abidjan, Abidjan, Cote d'Ivoire.

Objective. To determine the prevalence of HIV-1 and HIV-2 infections in cadavers and to examine causes of mortality.
Methods. All cadavers (hospital and community deaths) in Abidjan's largest morgue (Treichville) were prospectively studied. Each corpse was examined, and had post-mortem blood tested by ELISA for HIV-1 and HIV-2. Positives will be tested by Western blot. Death certificates were reviewed for cause of death.
Results. Four hundred and eight hospital and 116 community deaths were studied. In hospital cases (M:F ratio 1.9; 41% <15 years old) the prevalence of HIV-1 and/or HIV-2 infection (ELISA ONLY) was 25% in deaths <1 month; 16% 1-11 mos; 10% 1-4 years; 4% 5-14 years; 36% 15-19 years; and 48% 20 years or more. Peak seroprevalence (66%) was found in persons 30-39 years. Of 108 community deaths (M:F ratio 3:1) 90% were >15 years old; 36% were HIV positive. Wasting was more frequent in HIV positives (113/183; 62%) of all age groups than in seronegatives (139/341; 41%) (p<.001). Of 34 tuberculosis deaths 24(71%) were HIV positive. In cases with completed death certificates, causes of death potentially HIV-associated were reported in 79/111(71%) of HIV positive and in 73/294(25%) HIV negative cases (p<0.001). The relative frequency of HIV-1 and HIV-2 infections will be presented.
Conclusion. (1) AIDS attributable mortality is high. (2) Levels of HIV infection in the mortuary are high; staff must take suitable precautions.

T.B.0.9

ETUDE COMPAREE DES PREVALENCES HIV-1, HIV-2 ET HTLV-1 CHEZ LES LEPREUX DE 4 PAYS : COTE D'IVOIRE, CONGO, SENEGAL, YEMEN.

Mireille Verdier*, A.Sangaré**, E. Sassou-Guesseau**, A.Gaye**, Y.Al-Qubati** F.Denis* et coll. *Virologie et Neurologie CHU Dupuytren Limoges, France ; **Divers Instituts de Côte d'Ivoire, du Congo, du Sénégal et du Yémen.

Objectif : Déterminer la séroprévalence des rétrovirus HIV-1, HIV-2 et HTLV-1 au sein d'une population particulière : les lépreux. En effet, il apparaît une énorme disparité de prévalence HIV selon les rares publications concernant HIV et lèpre.
Matériel et méthodes : 1244 sérums de lépreux provenant des 4 pays cités ci-dessus ont été soumis à un test de dépistage :
des anticorps HIV (Abbott recombinant HIV-1/HIV-2 EIA)
des anticorps HTLV-1 (IF sur cellules HUT 102, clone B2 et Abbott HTLV-1 EIA) puis à une confirmation par Western Blot :
HIV : New Lav Blot 1 et 2, Diagnostics Pasteur
HTLV-1 :avec la souche HUT 102 + RIPA et dot blot quand necessaire.
Les sérums de population "témoin" ont été étudiés selon la même démarche.
Résultats :

	Lépreux			Témoins		
	nb	HIV +(%)	HTLV-1 +(%)	nb	HIV +(%)	HTLV-1 +(%)
Cote d'Ivoire	584	4,9	14,4	812	3,9	1,9
Congo	318	3,7	9,7	479	7	1,8
Sénégal	223	0,9	0,9	281	0,4	0,3
Yémen	119	0	0	51	0	0

Conclusion : Les résultats ont été analysés en fonction du pays, de la zone géographique, des formes de lèpre, de l'age, du sexe. La prévalence HIV est comparable à celle des témoins, alors qu'il existe des "clusters" pour HTLV-1 chez les lépreux de Cote d'Ivoire et du Congo.

T.B.0.10

CLINICAL MANIFESTATIONS OF HIV-1 AND HIV-2 INFECTIONS IN ABIDJAN, COTE D'IVOIRE

Odehouri, Koudou*; De Cock, K.*; Colebunders, R.**; Porter, A.*; Adjorlolo, G.*; Heyward, W.**; et al.
*Projet RETRO-CI, Abidjan, Cote d'Ivoire; **AIDS Program, Centers for Disease Control, Atlanta, GA., USA.

Objective. To examine the clinical manifestations of persons with serologic reactivity for HIV-1 and HIV-2.
Methods. For July - November 1988, hospitalised patients in Abidjan were interviewed and examined for symptoms and signs of the WHO clinical case definition for AIDS. Serum was tested for HIV-1 and HIV-2 by whole virus ELISA. All reactive sera will be tested by virus specific Western blot, and dually reactive specimens by type specific peptide ELISA.
Results. Of 1794 patients, 879 (49%) were reactive by ELISA; (9% HIV-1; 3% HIV-2; and 37% dually reactive). The WHO definition was 28% sensitive, 90% specific, and had a predictive value of 74% for HIV infection. Compared with seronegative individuals, persons with only HIV-2 reactivity more frequently met the WHO case definition for AIDS (10/36 vs 83/888; odds ratio 2.1), had chronic diarrhea (8/36 vs 44/899; OR 3.2), and had wasting (32/36 vs 348/891; OR 2.1). All major and minor criteria of the WHO definition were significantly associated with dual reactivity. Results of type specific peptide ELISA and Western blots will allow more accurate assessment of the association between symptoms and signs of AIDS and HIV-1 and HIV-2 infections.
Conclusion. ELISA reactivity to HIV-2 only as well as dual serologic reactivity was associated with manifestations similar to those observed in HIV-1 infected patients.

T.B.0.11

2 YEARS EXPERIENCE FROM AN AIDS CLINIC IN UGANDA

E.T. Katabira MRCP (U.K)
Department of Medicine, Makerere Medical School, Kampala, Uganda.

Objective: To present the experience gained from running the first clinic exclusively for HIV patients in one of the East and Central African countries significantly burdened by HIV disease.

Method: In 1987 an AIDS clinic was set up in Kampala Uganda, to follow up HIV infected people and to offer them treatment and counselling services.

Results: To date 799 patients have been seen 441(55%0 males and 358(45%) females. Male patients were older, with an average age of 32 and 28 for the females. Chief complaints included weight loss 80%, recurrent fevers 78% and recurrent diarrhoea 58%. There were 59 patients with Kaposi sarcoma of which 34 were male and 25 females. Sex ratio was 1:1.04 and age range was 16-55 years with an average of 32. Females were younger (average 28) than males (average age 34). This observation was statistically significant. Good information on the period between the time of onset and death was available in 52 patients. The mean was 71 weeks with a range of 8-288 weeks.

Conclusion: The clinic has shown that the survival of the symptomatic African patient can also be long. Given appropriate treatment of the opportunistic infections plus counselling this survival period could be improved.

T.B.0.12

EPIDEMIOLOGICAL APPROACH OF TUBERCULOSIS IN AIDS PATIENTS - BRAZIL. 1982 - 1988.

Chequer, Pedro*; Loures, L.* Rodrigues, L.*; Castilho, E.**; Bergamaschi, D.*.
*Ministry of Health, National Division of STD/AIDS, Brasília, Brazil, ** Oswaldo Cruz Foundation/Ministry of Health, Rio de Janeiro, Brazil.

Objective. To describe epidemiological aspects of Tuberculosis among Brazilian AIDS patients.
Methods. The data registered in the National Surveillance System for AIDS was analysed by crosstabulation according to gender, age, educational level and risk groups, and through chi-square statistics and the method of Mantel Haenszel.
Results. From the total of 5219 AIDS cases reported, 1068 (21%) presented Tuberculosis as an AIDS - related disease, at the moment of reporting. Tuberculosis is the third most frequent related disease preceded by Candidiasis (53%) and PCP (29%). The prevalence of Tuberculosis in AIDS patients rose from 10% in 1984 to a maximum of 22% in 1988.
There is a non significant difference between the prevalence rates for male (21%) and female (23%) cases.
The prevalence of Tuberculosis in the 15 - 39 age group was 3 times higher than that observed for patients 15 years old or less.
When comparing the prevalence of tuberculosis in patients with high level of education (10%) it was lower than that observed in the group of patients with inferior level of education (22%).
The prevalence rate of Tuberculosis for female AIDS IVDU(s) patients (34%) was greater than that observed for both female heterosexual cases (21%) and transfused female cases (13%).
The odds ratios of Tuberculosis for male IVDU(s) patients were 2 and 3 for homo/bisexual and hemophiliac patients respectively.
It was observed that there was no significant difference when IVDU and heterosexual male patients as well as IVDU and recipients of blood/components male cases were compared related to Tuberculosis as an associated disease.
Conclusions. Tuberculosis is a very important AIDS related disease considering its prevalence rates and its epidemiological aspects associated to demographic and some behavioural features of AIDS patients. The interaction between AIDS and Tuberculosis will have a great impact on the epidemiology of Tuberculosis and the clinical profile of AIDS in Brazil.

Traitement des infections par le VIH
HIV Therapy

T.B.O.13 AZT UPDATE

Fischl, Margaret. University of Miami School of Medicine, Miami, Florida, USA.

T.B.O.14 NEW ANTI-HIV DRUGS: HOPE FOR THE FUTURE

Thomas C. Merigan, M.D.
Department of Medicine, Division of Infectious Diseases, Stanford University School of Medicine, Stanford, CA 94305

It is clear that new therapeutic strategies must be developed for all stages of HIV infection and disease. As with most infectious micro-organisms, drug side effects and microbial resistance will limit the impact of any one drug to only certain selected clinical disease settings and patients and for limited periods in the natural history of the infection. Fortunately, at this time, more intense effort and funding has been directed at controlling this organism than any other agent in history. As a result many novel rationally developed chemical and biologic therapies are being explored. Both receptor based and post translational agents as well as several new reverse transcriptase directed inhibitors are in Phase I and 2 testing. An approach to setting the best dose, route and schedule of new agents is being developed based on surrogate markers, namely serum P24 and CD4+ cells. The latter are also being utilized for evaluation of the optimum dosage and the role of each component given in combination therapy. Combination therapy should diminish emergence of drug resistance and allow dose reduction to lessen both short and long term occurrence of side effects. Unfortunately, one of the most interesting combinations of two agents with different mechanisms of action (AZT and αIFN) is complicated by both agents showing hematotoxicity. Then, as is currently underway within the U.S. AIDS Clinical Trial Group, only very careful and complete probing of the full response surface will reveal the optimum combination. The use of biologics, like interleukin-2, are also complicated as one must work against the organism through host responses and hence their use can be very disease stage-specific. Yet, in all these areas, progress is being made and will be summarized in this presentation.

T.B.O.15 LES IMMUNOMODULATEURS : THERAPEUTIQUE ALTERNATIVE OU ASSOCIÉE DE L'INFECTION PAR LE VIH

Alain Pompidou Faculté de Médecine Cochin Port Royal Paris

Les immunomodulateurs sont des substances d'origine diverse susceptibles de moduler ou de modifier la réponse,à un signal donné,des cellules du systéme immunitaire.Notre compréhension des mécanismes de l'immunodéficience liée à l'infection par le VIH et des modéles animaux actuellement disponible est incompléte,Un immunomodulateur ne peut donc être proposé chez l'homme qu'aprés avoir déterminé un certain nombre de facteurs: son influence sur les différents éléments de la réponse immunitaire,sa toxicité,son antigénicité et ses propriétés antivirales éventuelles,enfin son éfficacité sur les modéles animaux les plus appropriés.
Une classification des immunomodulateurs est proposée : elle distingue,selon leur origine, deux groupes de substances: les substances homologues fabriquées par l'organisme lui-même au niveau ou en dehors du systéme immunitaire,les substances hétérologues comprenant des produits de toute origine : extrait de plantes, de bactéries ou produits de synthése.
Les différentes modalités d'utilisation sont envisagées en tenant compte, notamment des propriétésimmuno-stimulantes, immuno-restoratrices et immuno-dépressives propres à chaque condition d'utilisation des immunomodulateurs.Aprés avoir envisagé les différentes modalités de l'étude pré-clinique, différentes étapes du développement clinique seront proposées en se référant notamment aux recommandations de l'OMS.
Les indications de l'utilisation des immunomodulateurs comme traitement alternatif ou associé de l'infection par le VIH seront discutées.

T.B.O.16 RESISTANCE TO HIV DRUGS

Richman, Douglas D.*; Darby, G.** and Larder, B.A.**.

*University of California San Diego and San Diego VA Medical Center, USA, ** Wellcome Research Laboratories, Beckenham, U.K.

AZT resistant isolates of HIV can be isolated from the blood of patients with AIDS or AIDS-related complex during prolonged therapy with the drug (Larder, Darby and Richman, Science 243:1731, [1989]). These observations were made possible by a plaque reduction assay with a $CD4^+$ HeLa cell line. Fifty percent inhibitory (ID_{50}) values of isolates from untreated individuals ranged from 0.01 to 0.05μM. In contrast most isolates from patients who had received AZT for 6 months or longer exhibited decreased sensitivity with isolates from several patients showing increases of ID_{50} values of greater than 100 fold. Sequential isolates from several patients exhibited progressive, step-wise increases in resistance. Cross resistance to AZdU was observed in all 5 AZT resistant isolates, but no cross resistance has been observed to AZG, ddC, ddI, d4T, carbovir, foscarnet, or interferons α, β or γ. Studies with additional compounds, studies with isolates from patients with different disease status or drug therapy, and studies of mechanism of action are in progress. The results of some of these additional studies and the implications of these observations will be discussed.

Transmission périnatale du VIH
Perinatal Transmission of AIDS

T.B.0.17 PERINATAL TRANSMISSION IN INDUSTRIALIZED COUNTRIES

Peckham, Catherine. Institute of Child Health, University of London, London, United Kingdom.

T.B.0.18 ESTIMATES AND PROJECTIONS OF PERINATAL TRANSMISSION OF HIV

Chin, J. World Health Organization, Geneva, Switzerland

The global epidemic of HIV infections is believed to have started during the late 1970s/early 1980s. As of mid-1989 over 150,000 cases of AIDS have been officially reported to WHO. The majority of these reported cases have been among homosexual men and IV drug users, primarily in developed countries. However, it is becoming increasingly clear that these official reports grossly underestimate the true magnitude of disease and deaths attributable to HIV infections, especially among infants and children who acquired their HIV infection from their mothers during, or shortly after pregnancy (perinatal transmission).

Reliable estimates of the number and distribution of HIV infected infants are needed to begin the difficult task of responding to this increasing global problem. The Global Programme on AIDS (GPA) of WHO, has estimated the number of HIV infected women globally in 1987-88 to be about 1.5 million. Using an epidemiologically based projection model, GPA/WHO has estimated that close to 80,000 HIV infected infants may have been born in sub-Saharan Africa from 1980 through 1987. In 1985 to 1987 alone, the total number of HIV infected infants in Africa was estimated to be over 55,000; the estimated number of HIV infected births increased from less than 100 in 1980 to over 20,000 in 1987. Short-term projections for Africa using this model are that by 1992 there will be at least a cumulative total of about a quarter of a million infants infected with HIV due to perinatal transmission.

T.B.0.19 MODES, RATE, AND RISK FACTORS FOR PERINATAL TRANSMISSION OF HIV

Rogers, Martha; Centers for Disease Control, Atlanta, GA, USA

Objective To review current knowledge regarding modes, rate, and risk factors for perinatal transmission of HIV and to pose future research questions.

Methods. Information for this discussion comes from review of literature, analysis of CDC-reported AIDS cases, and prospective studies of perinatal transmission of HIV.

Results. Evidence indicates that mothers can transmit HIV to their infants in utero, through transplacental passage of the virus, and through breast feeding. Transmission during the intrapartum period, through exposure to maternal blood and vaginal secretions, probably also occurs, but has been difficult to prove. The proportion of perinatal transmission attributable to each of these 3 modes is unknown, however. The incubation period for CDC-reported perinatally acquired cases is significantly shorter than that of transfusion-acquired cases, suggesting that in utero transmission may play a significant role. The frequency of transmission from mothers to infants reported from several European and U.S. studies is around 30%. These studies largely involve women in the early stages of HIV infection. Risk factors for perinatal transmission are largely unknown; however, studies suggest that mothers with more advanced disease and those with depressed CD4 counts are more likely to transmit.

Conclusion. The increased transmission rates observed for mothers with advanced disease could be related to either a higher titer of virus or a more pathogenic strain. Further study of these risk factors and the timing of perinatal transmission is needed so that optimal prevention strategies can be developed and instituted.

T.B.0.20 DIAGNOSIS OF HIV IN INFANTS

Griscelli, Claude. Hôpital des enfants malades, Paris Cedex, France.

Pneumocystis carinii Infections

T.B.O.22 NATURAL HISTORY AND STAGING OF HIV INFECTION

Redfield, Robert. Walter Reed Army Institute of Research, Rockville, MD, USA

T.B.O.23 CLINICAL DIAGNOSIS OF AIDS AND RELATED DISORDERS

Masur, Henry.
Clinical Center, National Institutes of Health, Bethesda, Maryland, USA.

For individuals who are infected with HIV, morbidity and mortality are produced by three major processes: 1) opportunistic infections and tumors; 2) direct organ involvement by HIV; 3) immunologic processes such as antigen-antibody complex disposition. The quality and duration of patient survival can clearly be improved by prompt diagnosis of those processes that are treatable. Thus major emphasis must be directed at diagnosing the infectious complications that are responsible for causing 90% of deaths. Immunologic monitoring can predict when patients are most likely to be susceptible. Some diagnoses such as cerebral toxoplasmosis, cytomegalovirus retinitis, candida esophagitis, and perirectal Herpes simplex can be made presumptively on clinical or radiologic grounds and response to therapy can be assesses. Other diagnoses such as pneumocystis pneumonia, cryptococcal meningitis, and the causes of diarrhea must be made specifically by microbiological or histologic criteria.

AEROSOLIZED PENTAMIDINE *VS.* TRIMETHOPRIM-SULFAMETHOXAZOLE (TMP-SMX) FOR ACUTE *PNEUMOCYSTIS CARINII* PNEUMONIA (PCP): A RANDOMIZED DOUBLE BLIND TRIAL.

Montgomery, A. Bruce *; Edison,R.J.**; Hopewell,P.**; Sattler, F.R.***; Feinberg, J.****; Feigal, D.W.**; and the *LyphoMed*/NIAID Consortium Investigators.
* State University of NY at Stoneybrook; ** University of California, San Francisco; *** University of Southern California;**** National Institues of Allergy and Infectious Diseases.

Objective: To evaluate the efficacy and safety of aerosolized pentamidine as treatment for acute PCP in AIDS patients.
Methods: Patients with suspected PCP are randomized at 24 centers pending confirmation of PCP and receive either aerosolized pentamidine (600 mg in 6 cc daily) or TMP-SMX (TMP:15 mg/kg/day + SMX:75 mg/kg/day) with either placebo aerosol or placebo IV. Standard treatment course is 21 days with six months follow-up for recurrences and adverse events.
Results: 205 of the target of 240 eligible patients have been enrolled (17 currently in treatment). Pooled data from the two treatment arms as of January 13,1989:

	N	Rate
Eligible patients completing acute therapy	188	---
Randomized drug changed for poor efficacy	43	22.9%
Expired during acute treatment period	13	6.9%
Major adverse event during acute treatment*	70	37.2%
PCP recurrence months 1-3 of follow-up (N=136)	8	5.9%
PCP recurrence months 4-6 of follow-up (N=74)	6	8.1%
Extrapulmonary pneumocystosis	0	0%
Pulmonary hemorrhage	0	0%

* *(Predominant adverse events: Rash, fever, neutropenia, nausea, elevated SGOT/SGPT)*

Conclusions: Rates of toxicity, initial treatment failure and mortality are not excessive relative to other studied PCP treatments. PCP recurrence rates are also relatively low.

T.B.0.27

THE IMPROVING SURVIVAL RATE AFTER INTENSIVE CARE FOR *P. CARINII* PNEUMONIA AND RESPIRATORY FAILURE

Wachter, Robert M*; Russi, MB**; Hopewell, PC**; and Luce, JM**
*Robert Wood Johnson Clinical Scholars Program, Stanford University, **San Francisco General Hospital and the University of California, San Francisco.

Objectives. To determine the survival rate of patients with AIDS, *P. carinii* pneumonia (PCP), and respiratory failure who are admitted to the ICU, and to determine whether an improving survival rate (as compared to an earlier era) can be attributed to patient selection.
Methods. The study used a retrospective cohort design. Patients with AIDS and PCP who were intubated for respiratory failure at San Francisco General Hospital between January 1986 and December 1988 were studied. Hospital survival rate, long-term outcome, and severity of illness (including APACHE II scores) were measured, and compared to those of patients with PCP and respiratory failure hospitalized between 1981 and 1985.
Results. The hospital survival rate for the 35 patients in the 1986-88 cohort was 40%, compared to 14% for the 42 patients in the 1981-85 cohort ($p<0.01$). Age, episode of PCP, time since AIDS diagnosis, vital signs at hospital and ICU admission, oxygenation, albumin, lactate dehydrogenase, and APACHE II scores did not differ significantly between the two cohorts. Anti-PCP therapy was similar in both cohorts. Although corticosteroid use was much more frequent in 1986-88 cohort than in the earlier era (77% vs. 5%), its use in individual patients was not associated with better outcomes. There was no significant difference in 1 year survival rates between the 2 cohorts (8% vs. 2%, by life table analysis).
Conclusions. The short-term outcome of patients with AIDS, PCP, and respiratory failure in 1986-88 has improved as compared to an earlier era. The improvement cannot be explained by patient selection, based on commonly measured prognostic variables, or by therapeutic advances. This improvement may result in a change in ICU utilization by patients with AIDS.

T.B.0.28

TRIMETREXATE (TMTX) SALVAGE THERAPY OF PCP IN AIDS PATIENTS WITHOUT ANY THERAPEUTIC OPTIONS: INTERIM RESULTS OF THE 1ST AIDS "TREATMENT IND" PROTOCOL

Feinberg, Judith, Katz, D; McDermott, C; Myers, M; Hoth, D; AIDS Program, National Institute of Allergy and Infectious Diseases, Bethesda,Maryland,USA

Objective: To evaluate TMTX salvage therapy of PCP in AIDS patients(pts) who cannot be treated with standard therapies (ST), trimethoprim-sulfa and IV pentamidine. TMTX is the first AIDS drug to be distributed under the FDA's new "treatment IND" mechanism, which permits access by any licensed US physician to a promising investigational drug with evidence of safety.
Methods: Pts with morphologically-confirmed PCP, polys + bands ≥ 1000, platelets $\geq 50K$ who have experienced serious toxicity to both ST and/or have not responded to ST are treated with IV TMTX 45 mg/m^2 x 21 days and leucovorin 30 mg/m^2 x 24 days. Successful completion of study therapy is defined as survival at 1 month follow-up.

Results:	Intolerant	Refractory	Intolerant/Refractory
	n (%)	n (%)	n (%)
no.treated(as of 12/5/88)	115	34	6
1st episode of PCP	52 (45)	33 (97)	5 (83)
intubated at entry	24 (21)	20 (59)	3 (50)
days of ST at entry(r)	10.8 (0-38)	17.5 (11-26)	9.6 (7-13)
died	34 (30)	27 (79)	3 (50)
survived	54 (47)	2 (6)	3 (50)
withdrew - adverse event	16 (14)	2 (6)	0 (0)

Conclusions: TMTX is an effective (39% survived) and well-tolerated salvage therapy for desperately ill AIDS patients. The "treatment IND" is a useful mechanism for providing wide access to promising investigational therapies.

T.B.0.29

ORAL CORTICOSTEROIDS PREVENT ACUTE RESPIRATORY FAILURE IN AIDS-RELATED PENUMOCYSTIS CARINII PNEUMONIA *

Montaner, Julio SG; Lawson, L; Levitt, N; Belzberg, A; Schechter, M; and Ruedy, J. AIDS Research Program, St. Paul's Hospital, University of British Columbia, Vancouver, BC, Canada.

OBJECTIVE. To assess the role of adjunctive oral corticosteroids in the prevention of acute respiratory failure in patients with moderately severe AIDS-related Pneumocystis carinii pneumonia (PCP).
METHODS. Randomized, double-blind, placebo controlled trial. A total of 60 patients are being studied. Inclusion criteria includes:

I. First episode of PCP
II. PaO_2 45 to 85 mm Hg. (FIO_2=21%)
III. No other active pulmonary pathology
IV. No contraindication for systemic corticosteroids
V. Not on anti-PCP medication for more than 24 hours

Consenting subjects are randomized in blocks of 10 to placebo or prednisone 60 mg/day PO OD for 7 days followed by a 14 day tapering regimen. Acute respiratory failure (ARF) is defined as a 10% drop in oxygen saturation at day 3 as measured by pulse oximetry while breathing room air. Patients developing ARF are considered a failure of treatment and the code is broken.
RESULTS. To date, 30 subjects have been studied. Mid point interim analysis demonstrates that ARF developed in 6 out of 15 patients receiving placebo versus 1 out of 14 patients receiving adjunctive corticosteroid therapy ($p<.05$ Fischer exact test). All 6 patients developing ARF in the placebo treated group recovered rapidly after the initiation of corticosteroid therapy. The single patient who developed ARF in the corticosteroid group went on to die on day 6. One further patient in the corticosteroid group, died after resolution of his PCP from an unrelated cause (CNS lymphoma).
CONCLUSION. Oral corticosteroids prevent the development of acute respiratory failure in patients with moderately severe AIDS-related PCP. Furthermore, our results support the use of corticosteroids after respiratory failure develops in patients with AIDS-related PCP.

T.B.0.30

EFLORNITHINE IN PCP CASES RESISTANT TO CONVENTIONAL THERAPY.

DON.E.SMITH. S.OWEN. M.NELSON. B.G.GAZZARD.
ST.STEPHENS HOSPITAL, FULHAM ROAD, LONDON, ENGLAND.

OBJECTIVE : To describe our experience with Eflornithine as a salvage treatment in HIV positive patients with Pneumocystis Carinii Pneumonia (PCP) having failed to respond to Co-Trimoxazole or Pentamidine.
METHODS : 28 HIV positive patients with a microscopically confirmed episode of PCP received Eflornithine (400mgs/kg) IV continous infusion having failed to respond to either Co-Trimoxazole or IV Pentamidine as assesses by worsening CXR, PaO2 and failure of temperature and respiratory rate to normalise.
RESULTS : 18 patients survived (64%) and 10 died during treatment with Eflornithine. There was no statistical difference between initial PaO2 in survivors vs non survivors but there was a worse CXR in non survivors vs survivors. No ventilated patients recovered. 30 adverse events in total were recorded : anaemia 13, thrombocytopaenia 5, and phlebitis 15. All patients receiving greater than 10 days Eflornithine survived. Eflornithine was discontinued due to marrow suppression in 3 patients.
CONCLUSION : Eflornithine is a valuable drug for salvage treatment of non responsive cases of PCP but does exhibit bone marrow toxicity.

T.B.0.31

CLINDAMYCIN/PRIMAQUINE FOR P. CARINII PNEUMONIA IN AIDS.

Toma, Emil; Fournier, S.; Poisson, M.; Morisset, R.;
Phaneuf, D.; Vega, C.
Hôtel-Dieu de Montréal and Université de Montréal, Montréal, Québec, Canada.

Objective. To assess the tolerance, safety and the clinical outcome of clindamycin/primaquine (Clin/Pri) in the treatment of P. carinii pneumonia (PCP) in patients with AIDS.
Methods. This is an open clinical trial including patients with AIDS in whom "conventional" therapy for PCP failed or was not tolerated. The clinical outcome was assessed in patients with proven or highly probable PCP. The tolerance and safety was monitored in the above patients and in patients with possible PCP.
Results. So far 33 episodes of PCP (19 proven; 8 highly probable and 6 possible) were treated: 1st episode -21 cases and 2nd episode -12 cases. The Clin/Pri was given after 2-26 days of "conventional" therapy in 27 patients and as the initial treatment in 6 cases. Clinical response was defined as: cure - 23 patients; improvement - 2 cases; failure- 2 patients. The onset of clinical response was less than 48 h in 18 patients, 72 h in 5 patients and 6 days in 2 patients. Adverse reactions were encountered in 15 out of 33 patients: morbiliform rash in 14 patients (with fever, leukopenia or nausea in 3,2 and 1 of them respectively); mild diarrhea - 1 case. The duration of follow-up was 1 week 11 ½ months; eight patients were followed for more than 7½ months. In spite of no specific anti PCP prophylaxis only 3 patients had a relapse after 10, 10 and 9 months respectively.
Conclusion. Our results prove that a controlled comparative trial with Clin/Pri in the therapy of PCP in AIDS patients is feasible and worthy.

Problèmes de laboratoire dans le diagnostic du SIDA
Laboratory Issues in the Diagnosis of AIDS

T.B.0.32

LES ANTIGENES HIV-1 CIRCULANTS

Christine ROUZIOUX
Hôpital Necker-Enfants Malades, Paris, France.

La présence d'antigènes HIV-1 dans le sérum de sujets infectés est le reflet de la replication persistante du virus dans l'organisme. Leur détection est réalisable par des techniques d'immunocapture qui sont commercialisées. Ces techniques sont fiables, faciles à réaliser, sensibles et reproductibles à condition de connaître les limites de leur utilisation et de l'interprétation des résultats obtenus :

- le dosage des protéines virales doit être exprimé en pg/ml pour obtenir une bonne reproductibilité ;
- l'évaluation de la valeur-seuil doit être faite dans ses plus basses limites ;
- l'utilisation de détergents capables de lyser le virus est nécessaire pour l'obtention d'une meilleure sensibilité et, en fait, permet l'évaluation de deux paramètres différents : les protéines virales solubles d'une part, et les particules virales complètes d'autre part. On démontre qu'il n'y a pas de proportionalité directe entre ces deux paramètres, dont la valeur prédictive pourrait être différente.

Les antigènes HIV-1 circulants représentent un élément essentiel et indispensable pour le suivi biologique des patients et pour l'évaluation des thérapeutiques anti-virales. La présence d'antigènes HIV-1 circulants est le plus souvent corrélée à une évolution clinique défavorable. Cependant, l'absence d'antigénémie circulante chez certains sujets atteints de SIDA pose le problème de l'interférence des anticorps et des immuns-complexes et révèle bien que cet examen est certes le reflet d'une replication virale, mais aussi celui d'un équilibre antigènes/anticorps complexe.

SEROLOGY TESTS FOR THE DIAGNOSIS OF AIDS

M.V. O'Shaughnessy, Federal Centre for AIDS, Ottawa Canada

The serological tests most commonly used for the diagnosis of HIV infection have been enzyme immunoassays using whole viral lysate to capture anti-HIV antibodies. These screen tests have been configured to have high sensitivity and specificity; consequently, all positive results must be validated by a second procedure, such as immunoblot, immunofluorescence (IFA) or radioimmune precipitation (RIP). In most settings, these tests are highly reliable and quality assurance programs have demonstrated this. In some countries, these assays have been modified to detect antibodies eluted from dried blood spots for use in large scale epidemiological studies. Newer HIV screen tests include those using recombinant proteins, synthetic peptides and antigens from both HIV-1 and HIV-2 as the capture antigens. Competitive EIA tests are particularly suitable for differentiating HIV-1 and HIV-2. Immunoblots utilizing recombinant proteins are available and have undergone preliminary evaluation. Simple, often rapid, HIV antibody detection assays have been developed for use in developing countries and emergency situations in developed nations. The performance characteristics of these tests can be quite good, but positive results must be verified by another method such as RIP, IFA or immunoblot. Antigen capture assays may be used to detect HIV p24 in serum. This procedure has been used both for monitoring the efficacy of drugs under clinical evaluation and providing a prognostic indicator of patient outcome. The efficacy of most of these commercially available reagents is excellent, but continued successful delivery of testing strategies requires adequate product and user quality assurance programs. International collaborations, for example, those sponsored by the World Health Organization and the Pan American Health Organization have been established to assist in the development and implementation of quality assurance programs.

Viral Culture as an Adjunct to Clinical Trials: Isolation of AZT-Resistant Variants of HIV-1.

Mark A. Wainberg*; Rooke, R.; Tremblay, M.; Soudeyns, H.; Fanning, M.; Montaner, J.S.G.; O'Shaughnessy, M.; Gelmon, K.; Falutz, J.; Tsoukas C.; Gill, J.; Ruedy, J.
*Jewish General Hospital and McGill University, Montreal, Canada.

Our laboratory has participated in a Canadian AZT trial, designed to assess the effects of this drug on patients with Group II or III HIV-associated disease. Seventy two patients entered into this trial received 600 mg AZT per day for 18 weeks, 900 mg for 9 weeks and 1200 mg for an additional 9 weeks. After 36 weeks, drug was withheld for 6 weeks and started again after 42 weeks at 1200 mg per day. Attempts to culture HIV were routinely carried out during this period. A significant increase in the percentage of cases from whom HIV could be successfully isolated was observed both at the end of the drug wash-out period, and during the period following (80% postwash-out vs 40% prewash-out). This corresponded to decreased time to culture positivity following the wash-out period (11 days vs 19 days).

We have also shown that HIV could be isolated under conditions in which AZT (10 μM) was included in the primary viral culture medium in each of two cases in which patients had received AZT for longer than 36 weeks. Assessment of frozen viral isolates, obtained from patients on long-term AZT therapy, has revealed the presence of AZT-resistant virus in each of 9 additional cases. This property of drug resistance appeared stable, and did not disappear when such viruses were replicated in the absence of drug. These AZT-resistant isolates were, however, susceptible to inhibition by each of four other nucleoside analogues. Supported by Health and Welfare Canada.

T.B.0.36

NEW TECHNOLOGIES FOR THE DIAGNOSIS OF AIDS

Schochetman, Gerald. AIDS Program, Centers for Disease Control, Atlanta, GA, USA.

Specific testing for HIV antibodies and virus markers has permitted accurate diagnosis of AIDS and HIV infection. As the AIDS epidemic continues to spread, there will be a sustained need for more sensitive and quantitative assays. Higher sensitivity is needed to permit earlier diagnosis of infection which will become increasingly important as effective therapeutic interventions are developed to prevent the disease. Higher specificity is needed to decrease the number of false positives and to permit correct diagnosis of HIV infection in a larger spectrum of clinical situations where there is an incomplete or indeterminate antibody profile. Quantitative tests for monitoring the virus burden and state of activity in an infected person are also needed to improve the ability to assess the clinical status of the patient and to evaluate the efficacy of new drugs and possibly vaccines.

The use of rDNA-derived antigens has already shown great promise in the advancement of diagnostic testing. For developing countries, the availability of rapid, simple and inexpensive tests for HIV infection will offer the greatest hope for prevention of transmission of the virus particularly through screening of the blood supply. The application of DNA probe technology, particularly PCR, has already opened a new horizon for direct detection of the virus. This technology has proven useful for detecting infection in seronegative persons, for measuring virus expression and for finding and discriminating variant HIVs.

Diagnostic testing for HIV will remain an important aspect of disease control even as prevention and therapy are developed for these infections. Fortunately, technology advancement for diagnosis of retrovirus infections has entered a very dynamic phase and considerable progress can be expected in the development of novel diagnostic tests and test applications.

Pharmacologie et toxicité de l'AZT
AZT Pharmacology and Toxicity

W.B.0.1

PHARMACOKINETICS OF ZIDOVUDINE IN EARLY HIV-INFECTED HOMOSEXUAL MALES.*

Ruedy, John; Montaner, JSG; Le, T; Gelmon, K; Fanning, M; Smith, J; Falutz, J; Tsoukas, C. Multicentre Canadian AZT Trial (MCAT). Canada.

OBJECTIVE. To characterize the pharmacokinetics of zidovudine (ZDV) in early HIV-infected homosexual males within the frame of the multicentre Canadian AZT trial (MCAT).
METHODS. DESIGN: Multicentre, prospective, dose range finding study. SUBJECTS: HIV positive homosexual males belonging to CDC group II, III and IV C2 with helpers > 270 M/L. INTERVENTION: Following a 3 week observation period, volunteers were treated with ZDV 600 mg/day for 18 weeks, 900 mg/day for 9 weeks and 1200 mg/day for 9 weeks followed by a washout period of 6 weeks after which they were re-started on ZDV at 1200 mg/day or the highest previously tolerated dose. Upon re-initiation of therapy timed blood samples were obtained after a single 400 mg ZDV dose for serum level measurement by HPLC of ZDV and it glucuronidated metabolite (G-ZDV). Serum levels were obtained at 0, 20, 40, 60, 90, 120, 180, 240, 300 and 480 minutes. ANALYSIS: Analysis of variance was performed to compare mean area under the curve (AUC), peak serum level (C max), time to peak serum level (T max) and half life (T 1/2) of ZDV and G-ZDV between different CDC groups and study sites.
RESULTS. Data from 59 subjects was available at the time of this analysis. They were distributed as follows: Pharmacokinetic data (mean ± SD) is shown below. CDC groups II:16, III:25, IVC2:18; Study sites Montreal 20, Toronto 16 and Vancouver 23. No significant differences were found between CDC groups or study sites.

	ZDV	G-ZDV	BOTH
AUC	9.52 ± 5.79	34.90 ± 11.32	42.54 ± 12.03
C max	7.50 ± 4.99	21.27 ± 7.63	27.32 ± 9.12
T max	0.92 ± 0.41	1.15 ± 0.49	1.09 ± 0.52
T 1/2	1.91 ± 2.47	1.67 ± 2.12	1.32 ± 1.31

CONCLUSIONS: This preliminary analysis suggests that zidovudine pharmacokinetics in early HIV-infected homosexual males is similar to that described in AIDS patients. Although a considerable degree of inter-subject variability was present this could not be accounted for on the basis of CDC group or study site.

* Supported by a grant from the National Health Research Development Programme (NHRDP), Health and Welfare, Canada.

W.B.0.2

A PHASE ONE STUDY OF ZIDOVUDINE (AZT) IN INFANTS, LESS THAN THREE MONTHS OLD, AT RISK FOR HIV INFECTION.

Boucher, François D.*; Prober, C.G.*; Arvin A.M.*; Modlin J.F.**; Maha M.***; LaFon S.***; Weller S.***; Blum R.***; and the NIAID AIDS Program.
*: Stanford University School of Medicine, Stanford, CA, USA. **: Johns Hopkins U., Baltimore, MD, USA. ***: Burroughs-Wellcome Co., Research Triangle Park, NC, USA.

Objective. To determine the safety, tolerance, and the pharmacokinetics of AZT in infants, less than three months of age, exposed at birth to HIV.
Methods. Eight asymptomatic infants, < 3 months of age, who were born to HIV positive mothers were enrolled in a phase 1 study of AZT. The first 5 infants received single, 2 mg/kg doses of AZT IV on days 1 and 14, and PO on days 2 and 15; they were then treated with AZT, 2 mg/kg PO q6h from day 16 to 45. The subsequent 3 infants received single, IV doses of 3 mg/kg on days 1 and 46, and PO on days 2 and 45; then 3 mg/kg PO q6h from day 3 to 44. After each of the single doses, blood samples for AZT levels were drawn at regular intervals over 8 hours. Single CSF samples were also obtained at varied times through a dose interval. The drug was continued for up to six months in 4 infants proven to be infected with HIV.
Results. AZT was well tolerated by infants, with only one developing anemia (Hb≤10.0) during therapy, and none neutropenia (ANC≤500). Total body clearance (Cl) of AZT increased significantly, with a concurrent decrease in half-life ($T_{1/2}$) after 30 days of age (Table). Cl in infants > 30 days was comparable to that in adults. Oral absorption was satisfactory, and bioavailability (F) varied with age, from .52 to .81(Table). CSF:plasma ratios ranged from 0.13 to 0.50.

Age Group	$T_{1/2}$ (hrs)	Clearance (ml/min/kg)	F (2mg/kg) (%)
≤30days	2.29±0.76	17.2±5.69	0.81±0.17
>30days	1.5±0.29	23.8±2.37	0.52±0.04

Conclusions. AZT, at oral doses of 2 mg/kg q6h in infants < 1 month, and 3 mg/kg q6h in infants > 1 month of age results in concentrations comparable to those attained in adults receiving therapeutic doses. AZT is well tolerated by infants at these doses.

W.B.0.3

PHARMACOKINETICS OF ZIDOVUDINE IN IDU RELATED HIV INFECTION.

*Brettle RP, *Jones GA, *Bingham J, +Spacey BEM, +Weatherley B, +Churchus R, *I.D.U., City Hospital, EDINBURGH. +Wellcome Research Laboratories, BECKENHAM; U.K.

Objective: A pharmacokinetic trial of zidovudine in injection drug use (IDU) related HIV.
Methods: 6 males and 6 females, with a mean age of 26.5 years (22-39) were treated with Zidovudine. They appeared to have discontinued IDU but were currently using orally or by inhalation cannabis, benzodiazepines, methadone, and/or dihydrocodeine. They spent the first week in hospital on 250 mgm. zidovudine 6 hourly. Three sampling periods of 6 hours over 14 days occurred to determine the pharmacokinetics of zidovudine.
Results: Differences in the pharmacokinetics of AZT were observed for all parameters in the 10 patients on oral opiates, benzodiazepines or cannabis (Gp I) compared to the two patients taking only cannabis and/or benzodiazepines (Gp II) and reported normal values (Gp III).

	Gp I (± S.D.)	Gp II (± S.D.)	Gp III (± S.D.)
Area Under Curve (uMol.hr)	12.4 ± 4.0	4.6 ± 1.25	6.51 ± 1.71
t1/2 (h)	1.04 ± 0.31	0.73 ± 0.08	1.0 ± 0.49
Clearance (ml/min/kg)	23.3 ± 7.2	58.6 ± 24.6	36.6 ± 4.7
Peak (uMol)	7.7 ± 3.8	2.83 ± 1.4	5.01 ± 1.25

Conclusion. Oral opiates and benzodiazepines alters the pharmacokinetics of zidovudine. The mechanism is as yet unknown and therefore further studies are required.

W.B.0.4

PROBENECID INHIBITS THE METABOLIC AND RENAL CLEARANCES OF ZIDOVUDINE IN HUMAN VOLUNTEERS

Hedaya, Mohsen A.; Elmquist, W.F. and Sawchuk, R.J.
University of Minnesota, Minneapolis, Minnesota, USA.

Objective. Probenecid is a drug which may be coadministered with zidovudine (AZT) to slow its elimination rate, allowing the attainment of the desired therapeutic outcome while administering lower doses of AZT. The main objective of this work was to examine the mechanism of this interaction and to quantify the effect of probenecid on the metabolism and renal excretion of AZT during a balanced crossover study in two normal volunteers.
Methods. AZT was administered as a 200-mg single oral dose in the absence (control) and the presence (probenecid treatment) of probenecid with a one-week washout period between treatments. Probenecid treatment was 500 mg oral doses every 6 hours, started three days before AZT administration. Plasma and urine samples were collected frequently over a 12-hour period, and analyzed for probenecid, AZT, and AZT glucuronide (GAZT) using a sensitive and specific HPLC method.
Results. During the probenecid treatment, the probenecid plasma concentrations ranged from 100-150 μg/ml. Probenecid affected neither the protein binding nor the plasma/RBC distribution of AZT. Probenecid coadministration increased the AZT AUC to twice its control value, resulting from a 50% decrease in AZT total body clearance. The AZT renal clearance, calculated from renal excretion rates and average plasma concentrations, decreased from 350 ml/min to 220 ml/min during the probenecid treatment. This effect on renal clearance corresponds approximately to a 50 % decrease in the net renal secretion clearance.
Conclusion. Our results have shown that probenecid inhibits AZT glucuronidation and AZT renal excretion in normal volunteers.

W.B.0.5

EFFECT OF ACETAMINOPHEN (ACET) ON THE PHARMACOKINETICS OF ZIDOVUDINE (AZT)

Koda RT, Ko Richard J, Antoniskis D, Shields M, Melancon H, Cohen JL*, Leedom JM, Sattler FR, University of Southern California, Los Angeles, CA, USA. *University of Kentucky, Lexington, KY, USA.

Objectives. Determine if the disposition AZT is altered by co-administration with ACET since both drugs are metabolized by hepatic conjugation.
Methods. Of 26 AIDS patients receiving 200 mg AZT every 4 hrs, 13 received 325 mg of ACET every 4 hrs for 72 hrs; 6 were treated with 650 mg every 4 hrs for 72 hrs; and 7 were treated with 650 mg every 4 hrs for 7 days. Prior to and at the end of the ACET treatment, serial blood samples were drawn and analyzed by HPLC for AZT and 5'-glucuronyl AZT (GAZT).
Results. The average pharmacokinetic parameters for AZT and GAZT before and after ACET treatment were not significantly different (p>0.05).

	AZT Parameters					
ACET Dose	Pre-ACET			Post-ACET		
	AUC	Cl	t½	AUC	Cl	t½
325 mg q4h x 3 da	1462.4	88.9	0.94	1594.6	81.5	0.84
650 mg q4h x 3 da	2532.5	51.3	1.36	2474.3	52.5	1.51
650 mg q4h x 7 da	1950.6	66.7	1.84	1369.7	94.9	1.04

Conclusions. Under the conditions of this study, concurrent treatment of AZT and ACET showed not significant effect on the dispositon or clearance of AZT or GAZT in AIDS patients. If the co-administration of ACET with AZT therapy causes increased hematologic toxicity, the mechanism probably does not involve the inhibition of glucuronidation of AZT.

This study was supported by the AIDS Clinical Trials Program of NIAID.

W.B.0.6

LONG TERM NON-HEMATOLOGICAL ADVERSE EFFECTS OF AZT AND ITS EFFECT ON PRE-TREATMENT SYMPTOMATOLOGY

M. Fanning*, J. Omachoff, J. Montaner, C. Tsoukas, K. Gelmon, J. Ruedy, et al, Universities of Toronto, British Columbia, McGill.
*Toronto General Hospital, Toronto, Ontario, Canada

Objective: To determine the long term effect of AZT on pre-existing symptomatology as well as the nature, severity and time course of side effects related to long term use of AZT initiated in early HIV infection.
Methods: The Canadian Multicentre AZT Dose Range Finding Study enrolled 74 HIV positive men (CDC groups IIB, III, and IVC2). Subjects were treated with AZT 600 mg/day for 18 weeks, 900 mg/day for 9 weeks, 1200 mg/day for 9 weeks, followed by a washout period of 6 weeks, after which they were restarted on 1200 mg/day or the highest previously tolerated dose.
Results: Initial symptomatic adverse effects of AZT were frequent and wide-ranging. Most commonly, they manifested as nausea (64%), fatigue (55%), headache (49%), mood disturbances (29%), and rash/pruritus (28%). In all subjects, adverse effects disappeared by the end of the 6 week washout period. Of those who reported a particular adverse effect upon starting AZT, 34% re-experienced nausea, 32% fatigue, 19% headache, 47% mood disturbances, and 8% rash/pruritus when therapy was reinstituted. Most common symptoms reported prior to the administration of AZT included chronic fatigue (28%), night sweats (22%), rash (22%), and chronic sinus congestion (18%). All of these symptoms were significantly reduced during the course of the trial.
Conclusion: Upon restarting AZT, non-hematological adverse reactions were reported by fewer subjects than with initial drug administration. AZT has an apparent effect in decreasing pre-treatment symptomatology.

Traitement : thrombocytopénie
Therapy: Thrombocytopenia

W.B.0.7 ZIDOVUDINE AS A POSSIBLE TREATMENT FOR THROMBOCYTOPENIA ASSOCIATED WITH AIDS AND ARC.

Stephen T. Green, D Nathwani, DJ Goldberg, RJ Fallon, DH Kennedy, WC Love;
Ruchill Hospital, Glasgow, U.K..

Objective: HIV-related thrombocytopenia is well-described and available treatments are generally unsatisfactory. The study examined whether or not zidovudine (azidothymidine) had a possible role in its treatment.
Method: 19 patients with ARC or AIDS (1 heterosexual non-drug user and 18 homosexuals) were maintained on zidovudine 200 mg four-hourly. Following starting the drug, regular haematological follow-up was conducted over a period of 12 weeks.
Results: 9 of the 19 patients were thrombocytopenic (defined as a platelet count of < 150 x 10^{9}/l) prior to starting zidovudine. By the end of the first week of treatment, 11 out of 19 (58%) exhibited a rise in platelet count of 20% or more compared to their baseline pre-treatment count. Of the 9 patients with low platelets prior to treatment, 7 showed a rise in count (of greater than 20% in 5 of these cases) at 1 week, while counts in one remained unchanged and one showed a fall from his baseline count. At 12 weeks, 4 out of the 11 responders (37%) had maintained this initial rise; these 4 patients had all been thrombocytopenic prior to zidovudine and all had also shown a significant rise at 1 week. The one initially-thrombocytopenic patient with a fall from baseline at 1 week showed a 58% rise from baseline by 12 weeks.
Conclusion: Zidovudine may represent a useful additional treatment for HIV-related thrombocytopenia.

W.B.0.8 THE EFFECT OF ZIDOVUDINE ON PLATELET COUNT IN HIV-ASSOCIATED THROMBOCYTOPENIA *

Montaner, Julio SG; Le, T; Gelmon, K; Fanning, M; Falutz, J; Tsoukas, C; Wells, G; O'Shaughnessy, M; Wainberg, M and Ruedy, J. Multicentre Canadian Azidothymidine Trial (MCAT), CANADA

OBJECTIVE. To characterize the nature, time course and dose dependency of zidovudine effect on platelet counts in thrombocytopenic HIV infected individuals within the Multicentre Canadian AZT Trial.
METHODS. DESIGN: Multicentre, prospective, dose range finding study. SUBJECTS: 12 HIV positive homosexual men; CDC groups IIB, III and IVC2; helper count >270 M/l and platelet count <150 G/l INTERVENTION: Following a 3 week observation period, subjects received zidovudine 600 mg/day for 18 weeks, 900 mg/day for 9 weeks, 1200 mg/day for 9 weeks, no drug for 6 weeks and 1200 mg/day or the highest previously tolerated dose for 18 weeks for a total of 60 weeks of therapy. FOLLOW-UP: Clinical and laboratory evaluations were performed at 3 weeks intervals. ANALYSIS: Analysis of variance was used to compare mean platelet values at each zidovudine dose. Where statistical differences were found analysis of variance was performed within the dose period to characterize timing and magnitude of the maximal change.
RESULTS. Initial platelet count (To) was 81 ± 37, and increased to 129 ± 51 ($p<.0001$) with low dose zidovudine, reaching a peak at 9 weeks (9 wks vs 0 wks, $p=.01$). Platelet count remained above initial values while on zidovudine (600 mg vs To, $p<.0001$; 900 mg vs To, $p= .0005$; 1200 mg vs To, $p =.0002$). The zidovudine effect on platelet count was not dose related (900 mg vs 600 mg, $p=.16$; 1200 mg vs 600 mg, $p=.25$; 1200 mg vs 900 mg $p=.82$). Platelet count decreased to initial values upon discontinuation of therapy (0 mg vs To, $p=.07$) to increase once again when therapy was reinstituted (1200' mg vs 0 mg $p = .036$) to levels above the initial counts (1200' mg vs To, $p<.0001$) and similar to those observed upon initiation of therapy (1200' mg vs 600 mg $p=.37$). The timing of the platelet count increases upon reinstitution of therapy was similar to that seen upon initiation of therapy. Overall subjects could be easily divided into sustained responders (n=4); transient responders (n=4) and non-responders (n=4).
CONCLUSION. Zidovudine therapy produced a sustained increase in platelet count among thrombocytopenic, HIV-infected individuals. Although a considerable degree of variability was observed, it is apparent that this effect is drug related but dose independent.

W.B.0.9 THE EFFECT OF ZIDOVUDINE ON HIV-ASSOCIATED THROMBOPENIA

[illegible]; Jäger H.; Kaboth W.
AIDS Study Group and 1.Medical Department
Schwabinger Krankenhaus, Munich, FRG.

Objective. Among 440 HIV-AB positive patients in all stages of HIV infection 20 (4.5%) had HIV-associated thrombocytopenia (platelet counts <100 000/qmm). The prevalence among homosexual men was 3.2%, among IVDA 7.8%. This study was designed to describe the effect of zidovudine on HIV-associated thrombopenia.
Methods. Seven patients with HIV-associated thrombopenia (4 CDC AIDS; 3 ARC) were treated with zidovudine, corresponding to the standard directions concerning indication and dosage (1000 mg/day). Platlet activity under zidovudine treatment was also observed in 9 non-thrombocytopenic patients (7 CDC AIDS, 2 ARC). Thrombocytes were counted, by a standard method, before zidovudine therapy and at week 2, 4, 10 and 20 after starting therapy.
Results. In patients with HIV-related thrombopenia we saw a significant increase in thrombocytes shortly after the beginning of zidovudine therapy. The average increase in thrombocytes after 1.8 weeks was 56 900/qmm (+94%), after 5.2 weeks 57 300/qmm (+106%), after 12.5 weeks 46 600/qmm (+79%) and after 21.0 weeks 80 000 (+169%) compared to the basic level (60 700/qmm; range 23 000-103 000/qmm). The average difference compared to the basic level in non-thrombocytopenic patients (224 000/qmm) was -0.[illegible] after 1.2 weeks, +3.0% after 4.7 weeks, +9.9% after 14.5 weeks and +7.8% after 21.1 weeks.
Conclusion. Zidovudine seems to be an effective treatment for HIV-[illegible]ted thrombopenia. After an observation period of 20 weeks, the initial increase of [illegible]ocytes could be maintained. The platlet increasing effect of zidovudine seems to be limited to patients with HIV-associated thrombopenia. The long-term effect, the efficacy in severe forms of HIV-associated thrombopenia and the pharmaco-physiological mechanisms will be subject to further investigations.

W.B.0.10 THE EPIDEMIOLOGY OF IMMUNE THROMBOCYTOPENIA (ITP): ARE INCREASES IN ITP IN THE POPULATION A MANIFESTATION OF THE HIV EPIDEMIC ?

Schlech, Walter*; Meadoly,C.*; Meagher,M.*; Turner,J.*;Dickey,D.*; et al
* Dalhousie University, Faculty of Medicine, Halifax, Nova Scotia, Canada

Objective. To determine if the HIV epidemic is reflected in increased rates of ITP in a province with a relative low incidence of HIV infection.
Methods. Two cases of HIV-associated ITP prompted a retrospective review of all cases of ITP in the province of Nova Scotia from January 1, 1980 to December 31, 1987. Hospital records were reviewed using ICD-9 codes and a strict case definition. In addition, all hematologists and internists seeing patients with ITP were identified and their records reviewed by mail. Demographic and clinical information was abstracted for analysis using standard census data. Patients were not directly contacted for assessment of risk factors for HIV infection.
Results. 224 cases of ITP were detected. The M:F ratio was 1:1.8. Ages ranged from 1 mo - 93 yrs. ITP rates increased from 2.1 X 10^{5} in 1980 to 3.8 X 10^{5} in 1986-1987. More cases (63/131) occurred in the sexually active age group (15-49 years) in 1984-1987 than in 1980-1983 (32/193)(p=0.03). Cases from ages 0-14 and >49 age group were stable (61 vs 68). Cases of known HIV-associated ITP (4) appeared in 1984, 1985 and 1986 in our study.
Conclusion. No previous population-based studies of ITP have beendone. Our study suggests that increases inITP may be explained by an increased incidence of HIV in a sexually active population. All patients with ITP who are sexually active should have diagnostic tests for HIV.

W.B.0.11 TREATMENT OF SEVERE HIV-RELATED THROMBOCYTOPENIA IN DRUG USERS

Galli,Massimo*; Landonio,G.**; Nosari,A.M.**; Lazzarin,A.*; Voltolin,L.* and De Cataldo,F.**.
*Infectious Diseases Clinic, Milan Univ.,**Dept. of Haematology, Niguarda Hospital, Milan, Italy.

Objective.To evaluate the response to High Dose Immunoglobulines, anti-Rh (D) immunoglobulines and AZT, in severe HIV-related Thrombocytopenia.
Methods.57 i.v. drug users with PTL<25x10^{9}/l and bleeding were treated in three different ways:

Patients	M	F	age	PTL(x10^{9}/l)	CDC stage			mean f.-up*
HDIg 0.4g/kg/die x 5 days *	20	9	19-34	2-18	9/II	20/III	0/IV	18.5
antiRhIg 15µg/kg/die x 8 days **	13	4	21-30	1-20	5/II	10/III	2/IV	7.8
AZT 800-1200 mg/die	9	2	19-34	5-22	0/II	8/III	3/IV	4.6

* with recalls; **mainteinance with 400 µg x 2/weekly; * months

Results.	Haemorragies		early response			late response		
	pre	post	100	50	25	100	50	25
HDIg	29/29	15/29	5/29	5/29	12/29	3/29	1/29	4/29
antiRhIg	17/17	3/17	6/17	6/17	2/17	5/17	4/17	2/17
AZT	11/11	2/11	2/11	2/11	4/11			

Conclusions.HDIg and antiRhIg have similar effects as emergency treatment. AntiRhIg is easier to administrate, but untoward effects (haemolysis in 3/17 c[illegible] with Hb<9g/l) may limit the use. During a short follow-up AZT increased PTL count and resolved the bleeding in 8/11 cases.

W.B.0.12 HIV-1 ASSOCIATED THROMBOCYTOPENIA:- DISAPPOINTING LONG TERM RESULTS OF SPLENECTOMY.

Shaunak, Sunil; Tyler, D. S.; Bartlett, J.A. and Iglehart, J.D.
Duke University Medical Center, Durham, NC, USA.

Objective: Steroids, intravenous immunoglobulin (IVIG), zidovudine and splenectomy have all been used in an attempt to treat symptomatic HIV-1 associated thrombocytopenia. Although no consensus exists on the best form of treatment, splenectomy has become popular. Since previous reports have provided only short term follow-up, we have evaluated the long term outcome of splenectomy when performed for HAT.
Methods: Nine patients (asymptomatic HIV positive =6, ARC=1, AIDS=2) had their spleens removed between 1986 and 1988. Platelet counts were checked monthly with a mean period of follow-up so far of 14.5 months (range 2-26 m).
Results: The mean (+/- sem) pre-operative platelet count (/mm^{3})was 22 000 +/- 9 000. Five patients received steroids, and 2 received IVIG prior to splenectomy. The mean weight of the spleens was 380 +/- 87 g. The immediate post-operative response was satisfactory with a mean platelet count of 342 000 +/- 88 000 at hospital discharge (mean hospitl stay 7.6 days), with 7 of the 9 patients having a count of > 100 000. However, the initial increase was not sustained in most patients. Only 2 patients have remained in complete remission (> 150 000) off all other medication, 5 patients have had a partial response (50 000 < pl < 150 000), and 2 have had no response (pl < 50 000, or a failure to increase by > 50 000). Platelet counts during the period of follow-up have ranged from 10 000 to 1 172 000. Four patients have required medical therapy {ZDV = 1, steroids = 3 (2 non-responders and 1 partial responder)} following splenectomy in an attempt to increase their platelet counts. There have been no post-operative episodes of clinically significant hemorrhage or pneumococcal bacteremia. Only 1 patient has had progression of HIV disease (ARC to AIDS). CD4 lymphocyte counts have remained stable in the 6 asymptomatic HIV positive patients.
Conclusion: In contrast to previous studies, our long term follow-up suggests that splenectomy when performed for HAT produces highly variable results. A complete response was uncommon with post-operative platelet counts fluctuating over a wide range. Additional medical therapy was frequently required. We therefore believe that clinicians should be cautious about splenectomy as the first line of treatment.

Qualité des soins offerts aux personnes atteintes de SIDA
Quality of Care for Patients with AIDS

W.B.0.13

SYMPOSIUM - Quality of Care for Patients with AIDS
- Role of Community Physician

Willoughby, Brian C; St. Paul's Hospital, Vancouver, British Columbia, Canada.

The community physician plays a pivotal role in provision of high quality care to persons with AIDS (PWAs). Any physician dealing with patients has the need to listen, to observe, to advise, and to console. In coping with AIDS, there is the additional need to advocate for our patients to provide quality care.

The physician plays different roles in each community in which he/she works. As members of the global community, one is guided by the aims of the World Health Organisation within the Global Programme for AIDS. These are information, education and communication to prevent further transmission of Human Immunodeficiency Virus and to provide care to those already infected. Within national and regional communities, one functions as educator, care-giver, and case reporter. Within the community of health care providers, one may be seen to be the coordinator of other care providers both institutional- and community-based, in addition to other roles.

Special roles may evolve in considering the community of patients of each physician. Physicians working within the general community have roles different from those of physicians whose patient community encompasses primarily gay/bisexual men, hemophiliacs or injection drug users

W.B.0.14

HOSPITAL CARE OF AIDS PATIENTS

Clumeck, Nathan
Free University of Brussels, St-Pierre University Hospital, Brussels, Belgium.

Due to the medical, social, ethical and psychological backgrounds of AIDS patients, HIV infection has to be viewed globally. To face the enormous medical complexity of HIV infection, re-examination of established care structures has to be considered. In this respect, as demonstrated by the SFGH model, hospital care should be a part of a coordinated program including out-patient clinic (ambulatory care) and community based organizations.

Depending available resources, commitment of health care providers, pre-existing structure such as infectious diseases department, and volume of patients inter hospital variability in care exists.

Ideally, hospitalized AIDS patients should benefit from a dedicated in-patient unit or at least an integrated network of relevant sub-specialities. To provide coordinated care and treatment for the complex multiple problems which overwhelm the patients, AIDS team should comprise infectious diseases specialists, oncologists, generalists in internal medicine and family practice, psychiatrists and psychologists and social workers in liaison with consultant physicians (mainly pulmonology, neurology, gastroenterology and dermatology). This multidisciplinary coordination should ensure optimal medical care and expert nursing and should reduce stress in AIDS care providers. In addition, psychological support for staff and volunteers as well as stress reduction program addressing education and information on infection control policy, ethical response and professional responsability and psychological burden should be part of hospital policy.

W.B.0.15

THE OUTPATIENT CLINIC IN AIDS CARE

Volberding, Paul. University of California, San Franisco, San Francisco, CA, USA.

The most effective, humane and efficient care for HIV disease requires well-conceived use of the resources outside the acute hospital setting, particularly of the outpatient clinic. In San Francisco, dedicated AIDS clinics have allowed for the provision of comprehensive medical and psychosocial care that is oriented to the patient's common needs. In one model, physicians of varying professional/specialty backgrounds work as a team supplemented by experienced nurse practitioners and physicians assistants. Social needs are provided by professional and volunteer counsellors, social workers and psychiatrists. Representatives of several community-based organizations are on the clinic staff and are able to provide effective referral to the services of these organizations. Also, clinic nurses are expert in HIV disease recognizing and resolving potential problems. This system combined with a model AIDS inpatient unit, has enabled the continual reduction in the average length of hospital stay without compromising the quality of medical care delivered. Costs of HIV disease care are lower in the San Francisco area than elsewhere in the United States.

The role of the outpatient clinic is central to the model of care in San Francisco. It serves as the home of the full-time provider staff and has provided a base for extensive studies of the cost of AIDS care as well as of new therapies. The opportunity to interact with a full range of HIV disease patients reinforces the commitment of the staff to maximize the time these persons spend in the community, further controlling overuse of in-patient services. This model works well in caring for a large population of patients most of whom are educated homosexual men in a city with a supportive attitude to AIDS issues. Clearly, stresses would exist in many other settings that complicate HIV disease care. Many hospitals are reluctant to openly provide AIDS care and populations of drug users with HIV infection are burdened by other health and economic concerns. Nevertheless, dedicated AIDS services have been used in diverse situations with common success.

W.B.0.16.A

AIDS AND US VETERANS: A COMPREHENSIVE CARE APPROACH IN A NATIONAL HEALTH CARE SYSTEM

Allen, Robert E.; Peterson, M. and Mather, S.H.
Department of Veterans Affairs, Washington, D.C., USA.

Objective: To describe how the Department of Veterans Affairs (VA) national health care system has responded to the needs of veterans with AIDS.
Methods: VA has one of the largest and most complex health care systems in the world, consisting of 172 medical centers, 231 outpatient clinics, 117 nursing homes, 27 domiciliaries and 194 Vet centers, employing approximately 230,000 individuals. VA has cared for approximately 7,000 AIDS patients using a comprehensive, multidisciplinary approach.
Results: Quality health care has been provided approximately 6% of all AIDS patients in the US in 145 different medical centers. The comprehensive continuum of care includes voluntary testing with intensive pre- and post-test counseling, clinical evaluation and treatment, as well as hospital based home care, chronic placement and hospice care, including bereavement counseling for partners and family. Advanced research is conducted in many medical centers by the same clinicians caring for the patients and patients have opportunity to participate in clinical trials and other research studies. Health professional and other staff training programs in AIDS are ongoing in the VA.
Conclusion: Over 6% of all of the AIDS patients in the USA come to the VA for care. This large, government run health care system has responded to the epidemic with clinical care, research and educational programs. These coordinated efforts have made it possible for any eligible veteran in the US to receive care for their AIDS related problems at any VA medical center.

W.B.0.16

HOME CARE THERAPY

Parker-Martin, Jeannee. Visiting Nurses and Hospice of San Francisco, San Francisco, California, USA.

In 1982, when Visiting Nurses and Hospice of San Francisco (VNH) began to receive referrals for people diagnosed with AIDS, Hospice interdisciplinary team members began to face organizational challenges regarding the provision of services for this population. Traditional family support systems were often insufficient, attendant care was often needed around the clock, and both private and public insurances were usually inadequate to cover the cost of care.

Since that time, VNH has provided support services to over 2000 persons with AIDS/HIV disease in the home setting or in the agency's residential care facility, Coming Home Hospice. This presentation will describe the development of the VNH AIDS Home Home Care and Hospice Program, and the special clinical features of the interdisciplinary team approach which combines the skills of nurses, social workers, trained paraprofessionals ("attendants"), and volunteers with the support of family members or friends to provide home and hospice care to persons with AIDS.

I. Overview of the AIDS Home Care and Hospice Program
    A. Development from 1982-1989
    B. Implementation of the interdisciplinary team approach

II. Management of the terminally-ill AIDS patient at home
    A. Several important clinical considerations
        1. Pain and symptom management
        2. Mental status deterioration
        3. Substance abuse

    B. Psychosocial Concerns
        1. Multiple loss issues
        2. Lack of traditional supports
        3. Minimum financial resources

III. Reimbursement considerations

W.B.0.17

CONTRASTING DETERMINANTS OF SUSCEPTIBILITY TO REITER'S SYNDROME AND PSORIASIFORM MANIFESTATIONS ASSOCIATED WITH HIV INFECTION.

Lenore J Brancato, S Itescu, ML Skovron, C Navarrete, G Solomon and R Winchester, Hospital for Joint Diseases, NYU Medical Center, New York, NY, USA

Objective. To investigate the possible contribution of genetic susceptibility to the development of HIV-related arthrocutaneous disorders that could be considered to be in the spectrum of spondyloarthropathies, and to determine their comparability to clinically similar disorders occurring among individuals not infected with HIV. These disorders include Reiter's Syndrome, psoriasiform rashes and other forms of chronic arthritis and enthesopathy such as psoriatic arthritis.
Methods. HLA typing was performed. All HLA class I alleles of the B and C loci, including those that have been described as disease susceptibility markers for these disorders in the general population, were assayed.
Results. In a case study of 21 patients with HIV-associated incomplete or complete Reiter's syndrome, HLA-B27 occurred in 15, or 71%. Antecedent infection with bacteria associated with reactive arthritis was documented in 30% of these individuals, further emphasizing the similarity of this syndrome with non-HIV-associated Reiter's syndrome. In contrast, among 8 patients with psoriasiform lesions identified in a prevalence study of 62 HIV clinic attendees, of whom one met the criteria of psoriatic arthritis, there was no statistically significant association ($p<.05$) between the presence of a psoriasiform rash and the HLA alleles Cw6, B7, B17, Bw16 or Bw57 when compared to 27 HIV infected controls without skin disease or to normal ethnically matched controls.
Conclusion. These findings suggest that among HIV-infected individuals the development of Reiter's syndrome involves an immune recognition event primarily dependent upon HLA-B27 molecules, whereas the pathogenesis of psoriasiform lesions in HIV patients, despite their resemblance to lesions in Reiter's syndrome, proceeds by distinct pathways that do not involve events influenced by specific polymorphic class I molecules.

W.B.0.18

CLINICOPATHOLOGIC AND IMMUNOCYTOCHEMICAL STUDY OF THE EYE IN AIDS: OBSERVATIONS IN 25 CASES

Hénin, Dominique ; De Girolami, U. ; Girard, B. ; Vazeux, R.* ; Le Hoang, P. ; and Hauw, J.J. ; Pitié Salpêtrière and *Institut Pasteur, Paris, France

Methods. The general medical, neurologic, and ophthalmologic findings in 25 cases of AIDS with complete post-mortem examination (including the eyes and CNS) were reviewed. All eye and CNS sections were embedded in paraffin and in celloidin and stained with H&E, PAS, Bodian/LFB (Loyez, Grocott, Ziehl. Immunocytochemical studies were performed on frozen and/or paraffin sections (eyes/CNS) to detect : HIV-1, CMV, Toxo, Crypto, JC and leukocyte/macrophage antigens.
Results : Males-20, Females-5; Age 23-61; Risk: Homo-15, IV-5, Africa-5.

		Opthalmology	Gen Path	Neuropath	Ocular Path
A) Cotton wool spots		10	-	-	1
B) Infections :	CMV	8	7	6	8
	Toxo	3	0	11	1
	HIV-1	ND	ND	12	?
	Other	0	7	2	retinitis
C) Tumors :	Kaposi sarcoma	0	11	0	0
	Lymphoma	uveitis	1	2	1

Conclusions. 1) The most commonly observed pathologic ocular finding in AIDS is CMV; the infection detected fundoscopically is always associated with systemic dissemination. In only 2 cases CMV was found both in the eye and the brain. 2) Cotton wool spots are frequent and transient at fundoscopic examination but difficult to demonstrate pathologicaly. 3) Toxoplasmosis/ lymphoma and Kaposi sarcoma, although often seen in the CNS and viscera respectively, rarely involve the eye.

W.B.0.19

CHANGING PREVALENCE OF MALIGNANCIES IN MEN AT SAN FRANCISCO GENERAL HOSPITAL DURING THE HIV EPIDEMIC.

Heyer, David M.*; Desmond, S.**; Volberding, P.* and Kahn, J.*. *San Francisco General Hospital (SFGH), San Francisco, California, USA; **University of California San Francisco, San Francisco, California, USA.

Objective. Kaposi's Sarcoma (KS) and Non-Hodgkin's Lymphoma (NHL) are malignancies recognized as index AIDS diagnoses. There is clinical suspicion that infection with HIV may increase the incidence of other malignancies. We have continued an ongoing study of hospital records to obtain the prevalence of malignancies in men at SFGH between 1979 and 1988.
Methods. We reviewed pathology, cytology, and autopsy reports on all men over 18 years old at SFGH between 1979 and 1988, and noted age, tumor type, primary site, and date of diagnosis.
Results. A. All Ages

	Year				
Tumor	79-80	81-82	83-84	85-86	87-88
KS	0	9	169	200	218
NHL	11	8	32	48	76
Basal Cell CA skin	26	28	38	75	72
Sq Cell CA anus	2	2	6	8	12
Condyloma Acuminata	16	29	35	62	61
Hodgkin's	1	4	13	14	7
Melanoma	4	5	4	12	12
Sq Cell CA Head/Neck	35	29	45	59	36
Sq Cell CA skin	12	13	22	17	16
Lung CA (all types)	56	42	37	64	39

B. By Age

	Year				
Tumor	79-80	81-82	83-84	85-86	87-88
Age 18-49					
KS	0	9	155	172	197
NHL	5	5	20	33	55
BCC	4	5	9	30	33
SCC anus	0	0	0	4	8
Age 50+					
KS	0	0	5	12	13
NHL	5	3	7	7	10
BCC	21	22	25	40	39
SCC anus	2	2	0	3	1

Conclusion. We describe an increased prevalence of several tumors at SFGH coinciding with the HIV epidemic. There is a striking increase in KS, NHL, Basal Cell CA of the skin, and Sq Cell CA of the anus that is most pronounced among young men. Risk group analysis is ongoing.

W.B.0.20

MALIGNANT LYMPHOMAS IN HIV INFECTED PATIENTS: CLINICAL AND PATHOLOGICAL FEATURES.

Schürmann, Dirk *; Dienemann, D. **; Ruf, B. *; Jautzke, G. ***; Langford, A. ****; Pohle, H.D. *
Departments of * Internal Medicine and ** Pathology, Rudolf Virchow University Clinic (Wedding); *** Department for Pathology, University Clinic (Steglitz), **** Clinic for Oral Surgery (Nord), Freie Universität Berlin, FRG.

Frequency, clinical features and histological types of malignant lymphomas in HIV infected patients were determined. Clinical and autoptical data from patients were evaluated. Organ tissue specimens were examined conventionally and using immunohistochemical staining techniques.

Incidence of ML: 18/190 (9 %) AIDS patients (patients with Hodgkin lymphoma [HL] were classified as having AIDS). NHL (n=14): High grade B-cell lymphomas with extranodal manifestations were found in all 14 cases. Burkitt lymphoma was seen in 2/14 cases. Most frequently found extranodal sites: CNS (n=7) and GI-tract (n=7). In three cases NHL was limited to the CNS. Treatment with common regimens (n=6) led to remission in 4/6 cases, five of these six patients died (survival time max. 6 months). One of the treated patients is alive (follow-up 36 months). HL (n=4): Mixed cell type HL in the stages 3 or 4 (Ann Arbor) was found in all cases. In two treated cases complete remission was achieved. These patients are still alive (survival time 15 and 24 months).

Malignant lymphomas in AIDS are predominantly NHL. High grade B-cell NHL with extranodal manifestations are most frequently found. Prognosis is commonly poor and may only be improved by treatment initiated early in the disease. HL are presumably more frequent than estimated and has a good prognosis. Hodgkin lymphomas are probably associated with AIDS.

W.B.0.21

THE VALUE OF LYMPH NODE BIOPSY IN HIV INFECTION

Forjaz Lacerda, M. J.*; Tavares, L.** and Madureira, R.*.
*Department of Pathology,**Department of Infectious Diseases, Faculty of Medicine / Santa Maria Hospital, Lisbon, Portugal.

Objective. to study the correlation between lymph node histopathology and clinical evolutio in HIV infection.
Methods. Thirty-nine patients with generalized lymphadenopathy, seropositive to HIV-1 (36 patients) or to HIV-2 (3 patients) were biopsed from July 85 to December 88. Conventional morphology and immunopathological studies were performed.
Results. Three histological subtypes of lymph node reactions were observed: Type I - Follicular hyperplasia with follicular alterations; Type II - Mixed hyperplasia; Type III - Lymphocyte depletion. Follicular alterations such as follicular fragmentation, islets of lymphocytes in germinal centers and naked germinal centers were observed in type I and type II. These two types were detected in PGL and ARC while lymphocyte depletion was always associated with AIDS. Immunological studies on frozen sections showed decreased CD4 lymphocytes with predominance of CD8 lymphocytes and severe alterations of the dendritic network of follicular dendritic cells. Tuberculosis with massive necrosis was observed in 9 cases (23.7%). In one case numerous large and pale histiocytes were associated with an atypical mycobacteria. HIV associated tumors were observed in 9 cases: Kaposi's sarcoma (3) and non- Hodgkin's lymphoma (6).
Conclusions. In our experience the histologic and immunopathologic patterns of lymph nodes are correlated with the clinical and immunological stage of infection. A progression in histological pattern follow clinical evolution.

W.B.0.22

INCREASED PULMONARY CAPILLARY VOLUME DURING AIDS-RELATED KAPOSI SARCOMA (KS).

Similowski, Thomas. ; Regnard J.; Dinh Xuan A.T.; Lockhart A.
Laboratoire d'Explorations Fonctionnelles Respiratoires, Hôpital Cochin, Paris, France.

Although rarely life-threatening, pulmonary localisations of KS (PKS) often raise the problem of the differential diagnosis from opportunistic infections and are usually ascertained by use of fiberoptic bronchoscopy (FO) and broncho-alveolar lavage (BAL).

AIDS patients, whatever their status towards KS or pulmonary infections, may have a reduced lung transfer factor for carbon monoxide (TLCO), as do asymptomatic HIV+ patients. We reasoned that PKS, even unapparent, might however result in increased capillary volume (Vc) because of the vascular nature of the tumoral proliferation. We studied therefore 11HIV+ patients and 13 AIDS patients with cutaneous KS (CKS). Age, sex, height and weight were, on average, the same in both groups. None of the patients had a history of AIDS-related or other pulmonary disease.TLCO was measured using the single breath technique. Membrane conductance (Dm) and Vc were calculated from determinations of TLCO made on two different gas mixtures.

Lung volumes, TLCO and Dm were, on average, the same in both groups but Vc was higher in CKS (132 ml, range 78-216 % of predicted) compared to HIV+ patients (100 ml, range 78-103% of predicted) ($p < 0.002$, Mann and Whitney U-test), with little overlapping between groups. Visible bronchial lesions or increased siderophage count in BAL fluid confirmed the diagnosis of intra-thoracic KS in 2 of 3 AIDS patients submitted to FO.

These results suggest that Vc measurement may be a useful non-invasive screening procedure for PKS, which could appear unexpectedly frequent. If these results are confirmed through radiologic and pathologic correlation, the finding of an increased Vc in an AIDS patient with CKS might render unnecessary invasive pulmonary investigations.

SURVIVAL OF PATIENTS WITH HEMOPHILIA-ASSOCIATED AIDS IN THE UNITED STATES

Stehr-Green, Jeanette; Holman, R; Mahoney M.
Centers for Disease Control, Atlanta, Georgia, USA

Objective. To examine the survival of hemophilic patients after the diagnosis of AIDS.
Methods. Using national hemophilia-associated AIDS surveillance data and the life-table method of analysis, we calculated the median survival and the cumulative probability of survival for all and selected subgroups of U.S. hemophilic patients after the diagnosis of AIDS.
Results. The median length of survival was 11.7 months; the cumulative probability of survival was 49.2 ± 2.0% at one year and 28.9 ± 2.3% at two years. The length of survival varied by age at the time of AIDS diagnosis:

	<13 years	13-29 years	30-59 years	60+ years
Median survival	12.0 mo	16.4 mo	9.8 mo	3.0 mo

Patients diagnosed before 1986 had a median survival of 6.4 months compared with 15 months for those diagnosed in 1986 or later. Length of survival did not differ significantly by race, coagulation disorder, AIDS manifestation at the time of diagnosis, or region of residence. Seven patients survived longer than 36 months after AIDS was diagnosed. These patients were more likely to have met only the 1987 revision of the CDC AIDS surveillance case definition than other patients.
Conclusions. Patterns of survival among hemophilic AIDS patients are similar to those reported in other risk groups, excluding patients with Kaposi's sarcoma. Length of survival decreased with increasing age and improved over time. In contrast to other risk groups, no difference in survival was associated with race.

W.B.0.25

NATURAL HISTORY AND PATHOGENESIS OF HIV INFECTION IN PATIENTS WITH HEMOPHILIA

Sullivan, John L.*; Koup, R.*; Brettler, D.**; Levine, P.**.
*University of Massachusetts Medical School, **Worcester Memorial Hospital, Worcester, Massachusetts, USA.

Objectives: To evaluate the natural history of HIV infection and HIV specific immune responses in patients with hemophilia.
Methods: A prospective study of 164 individuals with hemophilia was carried out over a 5 year period. Specific studies included HIV viral culture, serum p24 detection, lymphocyte surface marker analysis, neutralizing and ADCC antibody studies, and detection of HIV specific CTL activity.
Results: Over the first five years of observation 21 of 136 seropositive individuals (15%) developed AIDS. HIV was isolated from approximately 80% of infected individuals and 18% had detectable (>30 pg/ml) p24 core antigen in serum. Absolute numbers of CD4 T cells progressively declined in 84% of those infected while 16% had stable absolute CD4 cells. Activated (DR positive) CD8 T cells progressively increased from <2% to ≥12% of total CD8 T cells. Eighty percent of HIV seropositive individuals had detectable circulating cytotoxic T cells directed against HIV gag and envelope proteins. In addition HIV seroconversion was rapidly followed by the appearance of ADCC antibodies (titers from 1:1000 to 1:1,000,000) directed against only HIV envelope proteins. Neutralizing antibodies were slow to appear and persist in extremely low titer (from <1:5 to 1:80).
Conclusion: These results suggest that persistence of active CTL and ADCC responses in the absence of broad neutralizing antibody may result in progressive immune attrition with development of symptomatic disease.

W.B.0.27

CANADIAN NATIONAL HEMOPHILIA STUDY (CNHS): HIV INFECTION IN HEMOPHILIA (HEM) AND OTHER BLEEDING DISORDERS (1985-1989).

Poon, Man-Chiu; Ali, S.K.; Card, R.; Garvey, B.; Growe, G.; Kobrinsky, N.; Rivard, G.; Ross, E.; Rubin, S.; Strawczynski, H. and Tsoukas, C. Universities of Calgary, Memorial, Saskatchewan, Toronto, British Columbia, Manitoba, Montreal and McGill, Canada.

The CNHS initiated in Jan 1985 enrolled 372 patients from 12 Canadian Hemophilia Centers. These include 283 Hem A, 48 Hem B, 37 von Willebrand disease (vWD) and 3 others. There were 98 children and 274 adults. 210 patients had severe, 73 moderate and 89 mild diseases. In Jan 1989, 323 patients remained in the cohort, as 26 had withdrawn, and 23 had died. 16 of the deaths were due to AIDS. Several observations are notable: (I) The HIV seropositive (pos) rate was discordantly higher among Hem A (163 of 249 pos) than Hem B (2 of 43), vWD (4 of 28) or others (1 of 3). The most important determinant for pos was the use of non-heated factor VIII concentrates as 91% of those severe Hem A receiving this product were pos. Two of 4 pos vWD had received this product. One possibility is that before heated concentrates were supplied (Jul 1985), the Canadian volunteer plasma donation system was self sufficient for factor IX concentrates, whereas 50% of the factor VIII had to be imported. (II) Progression of HIV disease was evident. At enrollment, of the 164 pos patients (44% of 372) CDC II, III & IV diseases were 112, 46 & 6. At the lastest visits, 170 patients were pos (53% of 323). The CDC II, III & IV diseases were 47, 77 & 46. Including the 16 who died of AIDS, the number with CDC IV disease had increased from 6 to 62. (III) 6 patients seroconverted in 1987. This was traced to a factor VIII concentrate dry-heated at 60°C x 30 h.

W.B.0.24

CUMULATIVE RISK FOR AIDS AND OTHER HIV OUTCOMES IN A COHORT OF HEMOPHILIACS IN WESTERN PENNSYLVANIA

Ragni, Margaret V.*; Kingsley L.A.**;
*University of Pittsburgh School of Medicine, Hemophilia Center of Western Pennsylvania; **Graduate School of Public Health, U.S.A.

Objective. To describe the distribution of AIDS and HIV-related outcomes following HIV seroconversion in a cohort of hemophiliacs.
Methods. A well-characterized cohort (n = 84) of HIV-infected hemophiliacs from Western Pennsylvania, on whom HIV seroconversion data are known, have been followed prospectively for development of clinical manifestations of HIV infection including AIDS, AIDS-related complex (ARC), and CDC class IV infection. Kaplan-Meier estimates of cumulative risk for AIDS and other significant HIV outcomes by duration of HIV infection were determined.
Results. Of the 84 HIV-infected hemophiliacs, 27 (32%) have developed AIDS and 12 (14%) have developed ARC or CDC Class IV symptoms (thrush, herpes zoster). No cases of AIDS were observed in under two years' duration of infection. Using Kaplan-Meier product-time-limit-method estimates, by 4, 6, and 7-1/2 years' duration of infection, the proportion developing AIDS is 12, 29, and 43%, respectively. The cumulative estimate for developing either AIDS or ARC/IV by 7-1/2 year duration is 60%. By age, for those > 30, 18-30, and < 18 years, the proportion developing AIDS by 6 years after infection is 50%, 25% and 5% (p < .01).
Conclusion. Half of this cohort has developed AIDS or ARC/IV by 6 years' duration of infection. There appears to be a significantly shorter incubation to AIDS/HIV outcome in those over 30 years of age at seroconversion.

W.B.0.26

NATURAL HISTORY OF HIV IN PATIENTS OF THE BONN HAEMOPHILIAC COHORT STUDY.

Kamps, Bernd,S.*; Niese,D*; Brackmann,H.H.**; Maintz,C.*; van Loo,B.**, Kamradt,T.***
*Universitätsklinik Bonn, FRG, **Institut für experimentelle Hämatologie, Bonn, FRG, ***Massachusetts Institutes of Technology, Boston, USA

Objective. To describe the natural history of HIV-infection in adult hemophiliacs.
Methods. 343 adult patients at Bonn Hemophiliac Center were tested positive for HIV in 1985. Since 1986, 313 patients have been regularly followed up, including clinical examination, routine laboratory, lymphocyte subtyping, western blot and virus isolation.
Results. Six years after infection 16% (55/343) of the entire cohort had developed AIDS. The most frequent manifestation of AIDS was: PCP: 51%, HIV-encephalopathy: 25%, toxoplasmosis: 7%; NHL: 7%. One KS was observed.
In 86% of patients T4 cell count decreased 30% or more over the observation period. Prognostic markers for progression to AIDS (other than decreased T4 cell count) were elevated IgA, successful virus isolation and loss of anti-p24-antibodies.
In asymptomatic patients not treated with AZT (n=213), T4 cell count decreased 87 cells/year. Actual T4 cell distribution:

<100	101-200	201-300	301-400	401-500	501-600	>600	(T4-cells)
11	29	37	33	36	25	42	(patients)

Conclusion: Our findings suggest that most HIV-infected hemophiliacs will eventually develop AIDS.

W.B.0.28

NINE YEAR FOLLOW-UP OF A COHORT OF 112 ANTI-HIV SEROPOSITIVE HAEMOPHILIACS

Lee, Christine A. Phillips AN, Elford J, Janossy G, Griffiths, PD, Kernoff, PBA
Royal Free Hospital and School of Medicine, London, England.

Objective To assess the natural history of HIV disease in 111 infected haemophiliacs and 1 sexual contact.
Method Patients were reviewed at frequent intervals from the time of seroconversion (established by retrospective testing in 59 (53%) patients) until November 1988.
Results The first seroconversion was November 1979 and the last July 1985. The median length of follow-up from the first positive anti-HIV result was 5 years 1 month. By 30 November 1988, 65/112 (58%) patients were symptomatic and 21/112 (19%) had developed AIDS.

SYMPTOMATIC			AIDS		
	Thrombocytopenia	7 (6%)		HIV wasting syndrome	2
	Herpes zoster	11 (10%)		Oesophageal candida	2
	Bacterial infections	16 (14%)		PCP	10
	Oral candida	17 (15%)		Aspergillus pneumonia	1
	Seborrhoeic dermatitis	22 (20%)		MAI	1
				Cerebral toxoplasmosis	1
				Lymphoma	2
				Staphylococcal septicaemia with cerebral abscesses	1

Amongst 59 haemophiliacs with a known date of seroconversion the calculated cumulative incidence of symptoms was 90% and of AIDS 70% after 9 years of seropositivity (Kaplan-Meier estimate).
Conclusion This nine year follow-up confirms that the majority of anti-HIV positive patients progress to symptoms and AIDS. This cohort may provide a control for future studies of therapy in asymptomatic patients.

Infection par le VIH : atteintes à certains organes
HIV Infection: Organ Specific Involvement

W.B.O.29

CLINICAL GASTROINTESTINAL (GI) DISEASES IN AIDS
Kotler Donald, St Luke's/Roos., Columbia P&S, NY

The GI tract is vulnerable to immune deficits, due to poor physical protection and a contaminated external environment. Multiple complications occur, based upon specific immune deficits in secretory immunity, impaired T-cell function, macrophage dysfunction and diminished immune surveillance against neoplasms. Oral and esophageal disorders usually are due to yeast infections, while aphthous ulcers also are common. Intestinal diseases can be grouped as primary infections of enterocytes, secondary involvement from systemic or otherwise diseminated disorders, and a syndrome of inflammatory bowel disease. Enterocyte infections are caused by protozoans such as cryptosporidium, microsporidium and isospora produce a clinical picture of 'short bowel syndrome'. Secondary involvement by viruses, such as CMV, fungal infections, mycobacterial infections, or tumors are prevalent. There is a prominent systemic reaction such as wasting, as variable focal symptoms based upon the precise site of disease expression. Many HIV-infected patients have an inflammatory bowel disease of uncertain etiology. Recent studies suggest that HIV may be a primary pathogen in the gut. Liver disease often is related to mycobacterial or viral causes but biliary tract diseases can cause major morbidity. The major sequelae of intestinal dysfunction are progressive malnutrition and dehydration, though other specific medical or surgical complications occur.

W.B.O.31

CLINICAL CENTRAL NERVOUS SYSTEM INVOLVEMENT

Pederson, Court. Department of Infectious Diseases, Hvidovre Hospital, Hvidovre, Denmark.

W.B.O.32

PATHOLOGY OF THE CENTRAL NERVOUS SYSTEM IN AIDS
Michaud, Jean, Department of Pathology, Ste-Justine Hospital and University of Montreal, Montreal, Canada

The neuropathological examination of the human central nervous system in AIDS discloses lesions in most cases and these are frequently a significant cause of morbidity and mortality. A wide variety of lesions are found and these may be classified in four groups:
A) Direct Human Immunodeficiency Virus infection: the most characteristic process is a subacute encephilitis associated with multinucleated cells in ill-defined microglial nodules. White matter demyelination and vacuolar myelopathy are frequently part of the picture. The pathogenecity seems mostly mediated by the microglia-macrophage complex but the physiopathology is yet poorly understood.
B) Opportunistic infections: toxoplasmosis, several types of viral encephalitis (cytomegalovirus and PML being the most frequent), mycoses and mycobacterial infections are the most frequent.
C) Cerebral tumors: approximately 5% of AIDS patients will develop a primary intracerebral lymphoma which is usually of B-Cell Type. The Ebstein-Barr virus is presumed to play an important role in its etiology. Secondary CNS involvement by systemic lymphomas or Kaposi sarcomas is also found.
D) Non specific and non AIDS-related lesions.
In AIDS, two or several of the above mentioned groups of lesions or infectious organisms may be found in the same patient. Also, variations according to age groups, countries and patient subgroups as related to the etiology of the syndrome are now recognized.

W.B.O.33

THE LUNGS, THE CAUSE OF DEATH, AND BACTERIAL INFECTIONS IN AIDS: WHAT AUTOPSY STUDIES SHOW
Nichols, Larry; currently at Research Triangle Institute, Research Triangle Park, NC, USA

The lungs are the primary target of the most serious opportunistic infections of AIDS, the ones most frequently responsible for AIDS patients' deaths. Autopsy studies in the early years of the AIDS epidemic showed an extremely high rate of cytomegalovirus (CMV) infection at the time of death, with CMV pneumonia frequently playing an important role in the patients' deaths. Throughout the epidemic, most AIDS autopsy studies have corroborated the widespread clinical impression that Pneumocystis carinii pneumonia is the most common cause of death in AIDS patients. Recently, in a series of 46 AIDS autopsies at the New England Deaconess Hospital and Lahey Clinic in Boston, we found that bacterial (non-mycobacterial) infections were sole or contributing causes of death in 17 cases (37%). Eleven of these 17 bacterial infections were pneumonias due to Staphylococcus aureus, generally superimposed on Pneumocystic carinii pneumonia, CMV pneumonia or lung injury from previous bouts of such processes. Given the particular propensity of Staphylococcus aureus to superinfect lungs injured by other infections, recognized in multiple secondary epidemics of Staphylococcus aureus pneumonia following influenza epidemics, it is not surprising for Staphylococcus aureus to emerge as a secondary opportunist in AIDS patients with previous or underlying lung disease. These results confirm the importance of respiratory failure as a mode of death and show the importance of bacterial infections in general, and Staphylococcus aureus pneumonia in particular, in patients with AIDS.

W.B.0.34 INTRAVITREAL GANCICLOVIR ADMINISTRATION FOR CMV RETINITIS IN 11 AIDS PATIENTS

Pinna,R.[*]; d'Arminio Monforte,A.[**]; Lazzarin,A.[**]; Gagliardi, L.[*]; Novati,Roberto[**] and Bertoni,G.[*].
[*]Ophtalmology Clinic, [**]Infectious Diseases Clinic, University of Milan,Italy

Objective. Evaluation of intravitreal ganciclovir (DHPG) administration for CMV retinitis in AIDS patients, given poor intravitreal penetration of systemic therapy.
Methods. 11 AIDS patients (9 adults –6 PDA, 2 homosexual men, 1 sexual partner and 2 children) affected by CMV retinitis (3 in both eyes) were treated with a total of 5 intravitreal injections of DHPG (200 ug. each) in a period of 15 days. In 3 patients retinitis was the indicator disease of AIDS. CMV isolation was obtained in 5 patients. Retinal photos and fluorescein retinography were performed before, at the end of treatment and in the follow-up (every 3 mo.s).
Results. In 9 patients resolution of active necrotizing retinitis was rapid, leaving large atrophic pigmented areas and visual improvement. In 2 patients no changes in visual acuity were observed (because of optical disk involvement). No local complications were noted. Reactivation of retinitis occourred in 2 patients (18%.at 2nd and 3th mo.). 5 patients died (after 6±5 mo.s) (no one for CMV disease), 6 are still alive (after 3±1 mo.s).
Conclusions. Intravitreal DHPG therapy for CMV retinitis in AIDS patients seem to be more effective than systemic therapy (without adverse local reactions, and no systemic complications) and much more easely handled.

W.B.0.36 FOSCARNET TREATMENT OF CYTOMEGALOVIRUS RETINITIS IN AIDS

Mary M. Fanning, S.E. Read, M.F. Benson, A. Rachlis, S. Vas, V. Kouzesek, et al., Division of Infectious Diseases, Departments of Pediatrics, Medicine, and Opthalmology, University of Toronto, Toronto, Ontario, Canada.

Cytomegalovirus (CMV) retinitis is a common cause of blindness in AIDS in the absence of therapeutic intervention. 20 patients were enrolled over 9 months with acute first episode CMV retinitis in an open study using intravenous foscarnet. Infusion was given continuously over 21 days at a rate of 230 mgm/kgm/day with an initial bolus of 30 mgm/kgm. Upon completion, 7 patients were maintained at a dose of 90 mgm/kgm for normal creatinine infused over 3 hours, 5 days per week for up to 12 weeks. Fundoscopic exams, hematologic and chemistry analysis were monitored weekly. Acute therapy of 20 patients led to complete response in 15(75%), partial response in 2(10%) and deterioration in 3(15%). Of the 7 on maintenance, 1 withdrew due to inconvenience of protocol, 3 relapsed on day 12, 18, 30 respectively, 1 discontinued due to progressive disability and died 10 days later, and another showed progressive retinal deterioration. One finished and continues on compassionate therapy. Changes in renal function requiring modification of doses was the most common adverse event. 2 patients required peritoneal dialysis but recovered after discontinuing foscarnet. 3 patients showed thrombocytopenia, 3 leukopenia and half of the patients had progressive anemia. 6 of the 20 patients were on Retrovir during treatment and of these 1 developed leukopenia which could have been the result of Retrovir alone and 3 had anemia. Foscarnet successfully suppressed CMV in most patients. Recurrence of disease while on maintenance with further retinal damage requiring re-treatments emphasizes the need for better maintenance dosing.

W.B.0.38 INTESTINAL MICROSPORIDIOSIS AS A CAUSE OF DIARRHEA IN AIDS

Orenstein, Jan[*]; Steinberg, W.[*]; Chiang, J.[*]; Smith, P.[+]; Rotterdam, H.[**]; and Kotler, D.[++] [*]George Washington Univ. Med. Ctr., Wash., D.C., [+]NIDR, NIH, Bethesda, Md., [**]NYU Med. Ctr., N.Y., N.Y., [++]St. Luke's-Roosevelt Hosp. N.Y., N.Y., U.S.A.

Objective. Enterocytozoon bieneusi (EB), a new species of the phylum of protozoa, Microspora, has been reported associated with chronic diarrhea in a total of 11 AIDS patients in USA, Europe, and Africa. Diagnosis was based solely on the ultrastructural identification of this small intracellular parasite in SI biopsies. The objective of this study is to determine the role of intestinal microsporidiosis in the etiology of diarrhea in AIDS.
Methods. Small intestinal (SI) biopsies from AIDS patients with chronic diarrhea and without pathogens identified in standard paraffin sections and in stool specimens were studied by light microscopy (LM) of semi-thin (1-3um) plastic sections and transmission electron microscopy (TEM)
Results. EB microsporidial infection of the SI was diagnosed by TEM in 20 (22 biopsies) of 67 (71 biopsies) homosexual AIDS patients with chronic diarrhea and no other identified pathogen. Parasites and spores were visible by LM in plastic sections from 17 and 21 of the biopsies, respectively. In retrospect, parasites were also visible by LM in many of the standard H&E-stained sections. Infection was confined to villous enterocytes, especially of the tips, and was associated with degeneration, necrosis, and mucosal sloughing. Spores appeared to be released into the lumen from necrotic cells. Colorectal biopsies have been negative for EB.
Conclusions. EB infection of the SI may be an important cause of diarrhea in AIDS patients, and with experience, can be diagnosed at the LM level.

W.B.0.35 MONITORING OF CYTOMEGALOVIRUS (CMV) ANTIGENEMIA DURING TREATMENT OF SERIOUS CMV INFECTION IN AIDS PATIENTS

Sprenger, Herman G., Weits, J., Anema, J.T., Schirm J., The, T.H. University Hospital Groningen, The Netherlands.

Objective. To determine the effect of therapy against CMV on CMV antigenemia in AIDS patients in comparison with the effect on CMV viremia.
Methods. Prospectively 6 AIDS patients were followed. Three patients had CMV retinitis, 2 CMV related wasting disease and 1 CMV colitis. All patients received antiviral therapy against CMV in standard regimen, intravenous immunoglobulin (2 patients), ganciclovir (5) or foscarnet (1). Induction therapy was followed by outpatient maintenance therapy with ganciclovir starting at 5 mg/kg. Blood samples were assessed one to two times weekly for the presence of CMV by direct staining (by an immunoperoxidase assay) of CMV antigens (CMV Ag) in leukocytes (CMV antigenemia), quantitatively expressed as a number of CMV Ag positive cells, and by virus isolation (CMV viremia).
Results. Before treatment all patients were positive by direct CMV Ag detection, as well as by isolation of CMV. CMV immunoglobulin had no favourable effect, neither on the number of CMV Ag positive cells or on CMV viremia, nor on clinical symptoms. During induction therapy with ganciclovir or foscarnet both CMV antigenemia and viremia became negative in all patients. However, CMV antigenemia remained longer detectable (1–4 weeks) than CMV viremia (less than 1 week). During maintenance therapy (6–8 months) in 3 patients 1 continued to be negative for both antigenemia and viremia, 1 remained negative vor viremia, but was intermittent positive with a low number of CMV Ag positive cells and in 1 increasing CMV antigenemia predicted by 6 weeks positive CMV viremia and clinical deterioration, suggesting resistance to ganciclovir in spite of renewed induction therapy.
Conclusion. Detection of CMV antigenemia seems to be more sensitive than CMV viremia in monitoring the virological response to CMV induction and maintenance therapy. A rise in the number of CMV Ag positive cells during maintenance therapy could be an early marker for failure of antiviral therapy.

W.B.0.37 DIFFERENCES AMONG PULMONARY (PT), EXTRAPULMONARY (ET) AND DISSEMINATED TUBERCULOSIS (DT) IN HIV-INFECTED PATIENTS.

V Cárcaba, JA Carton, Z García, JJ Palacio, JA Maradona, JA Muñoz, JM Arribas. HOSPITAL UNIVERSITARIO DE OVIEDO. SPAIN.

OBJECTIVE. To establish clinical and prognostic differences in HIV-infected patients with PT and those with ET or DT included in AIDS according to new criteria.
METHODS. From 1984 to 1988, 53 seropositive patients were diagnosed of T due to M. tuberculosis culture (44), finding of granulomas with acid-fast bacilli (7) or clinical basis (2). Mean age was 30±6, 42 were men, 44 drug-addicts and in 45 T was the initial complaint to look for medical care. Only two patients have T before AIDS and all recived standard chemotherapy with a mean follow-up of 15.5 ± 14 months.
RESULTS. Treatment cured 90% of the patients and presently 79% of them survive. 25 cases showed PT (13 localized and 12 extended); 13 ET (8 lymphatic) and 15 DT (9 with miliary pattern). The chest radiographs showed focal infiltration with cavities in the upper lobes (22), atypical pattern (4) and miliary infiltration (9). The tuberculin test was positive in 37% and the most useful diagnostic test was sputum examen and culture. Main differences between PT and ET/DT were:

	P T	E/D T	P-value
Cases: 1984-86 / 1987-88	12 / 13	4 / 24	0.01
M. tuberculosis isolation	24	20	0.04
Lung symptoms / adenopathy	22 / 9	17 / 21	0.05
Positive tuberculin test	56 %	28 %	0.05
CD4 / µL (M+SD)	407 ± 155	179 ± 170	0.003
Opportunistic infections	6	20	0.001
Defervercesce since treatment	4.3 ± 3.5	28 ± 27 (days)	0.01
Overall deaths / T deaths	2 / 0	3 / 5	
Mean survival (months)	22 ± 17	9 ± 6	0.001

CONCLUSIONS. In Spain, HIV-associated T usually appears early in the course of HIV infection and shows a favorable response. Although it has been emphasized on its atypical manifestations, difficult diagnosis and poor survival, almost half of our cases manifested as typical PT with low case-fatality rate. During recent years it has been appreciated an increasing rate of ET and DT in relation with the progressive immunodeficiency of the HIV-infected population; however they continue with favourable responses to chemotherapy and satisfactory survival in the short-term.

W.B.0.39 IMPROVED SURVIVAL IN AIDS PATIENTS WITH OPPORTUNISTIC INFECTIONS.

Gold, Jonathan W. M.; Campbell, S.W.; Carrow, M; Wiedzwiecki, D. and Armstrong D.
Memorial Sloan-Kettering Cancer Center, 1275 York Ave. New York, N.Y.10021, U.S.A.

Objective. To examine changes in survival following opportunistic infections in AIDS patients since the beginning of the AIDS epidemic.
Methods. Survival following the diagnosis of each opportunistic infection was calculated using the Kaplan-Meier method in 780 AIDS patients seen at Memorial Sloan-Kettering Cancer Center since 1979. Results were examined by year of diagnosis and by comparing patients diagnosed prior to 1986 and during and after 1986.
Results. Number of cases and median survivals (months) for infections commonly diagnosed during life:

	PCP(#1)	T. gondii	M.tb	M.a.-c.	Cryptoc.
	#/ surv.	#/surv.	#/surv.	#/ surv.	#/surv.
1979-85	181/ 8mos	22/4mos	14/6mos	94/ 2mos	12/3mos
1986-88	191/ 18mos	10/10mos	10/11mos	68/ 4mos	20/6mos

Conclusion. Median survivals appear to have increased for some infectious complications of AIDS. Treatment differences included: introduction of zidovudine; use of PCP prophylaxis and more intensive follow-up with earlier treatment.

PREVALENCE AND PREDICTORS OF DEPRESSION IN GAY AND BISEXUAL MEN DURING THE AIDS EPIDEMIC: THE SAN FRANCISCO MEN'S HEALTH STUDY.

Castro, Frank*, Coates T.J.**, Ekstrand, M.**
*Stanford University, Stanford, CA, USA
**University of California, San Francisco, CA, USA

Objective. To describe prevalence and predictors of depression in gay and bisexual men living in an epicenter of the AIDS epidemic.
Methods. 568 single males participating in the San Francisco Men's Health Study (a population-based longitudinal study of single males in SF) were assessed in 1985 and 1987. Depression was assessed using the Center for Epidemiological Studies (CESD). 16 predictor variables (demographic, social support, loss to AIDS, health status, substance use, and homophobia) assessed in 1985 were analyzed for their predictive relationship to depression in 1987.
Results. 20% of the men met the criteria for depression in 1987. 54.9% had experienced the loss of a lover or friend to AIDS. 45.7% were seronegative, 38.2% were HIV+ asymptomatic, 6.9% had symptoms of ARC, while 4.6% had been diagnosed with AIDS. Predictors of depression in 1987 were previous depression, HIV disease progression, loneliness, loss of loved one to AIDS, satisfactoin with social support, and numbers of persons one could count on for support. These accounted for a significant proportion of the variance (r= .64, R2=.40).
Conclusion. Depression is a common experience for gay and bisexual men in San Francisco. Strategies for coping for worsening health status, for dealing with loss, and for gathering and keeping social support may assist individuals in coping withthe epidemic.

W.B.O.41

IS THERE ADAPTIVE "HABITUATION" TO LOSS IN THE AIDS EPIDEMIC?

Neugebauer, R.; Williams, J.; Rabkin, R.; Remien, Robert H.; Gorman, J.; HIV Center for Clinical & Behavioral Studies, NYS Psychiatric Institute and Columbia University, New York, NY, USA.

Objective. To explore the psychiatric toll of AIDS deaths and of other major, negative life events among NYC gay men. Methods. Data derive from 160 gay men participating in a prospective cohort study. Subjects were predominantly White, middle class, with a mean age of 38; 75% were HIV+. Current depressive symptoms were assessed clinically (Hamilton Depression Scale) and by self-administered checklists (e.g., Dohrenwend Demoralization Scale; SCL-53, depression subscale). Results. Contrary to expectations, no direct association was found between subjects' reports of the number of deaths from AIDS (overall and categorized separately into close friends, former lovers, lovers at the time of death) since the start of the epidemic or in the last 6 months, and any measure of depressive symptoms. For example, the correlation of number of recent losses with level of demoralization was -.15 (p<.10). Analyses dichotomizing recent deaths into none vs. one or more; controlling for potentially confounding variables, e.g., social network, and for HIV status, did not alter these results. In marked contrast, other recent negative events correlated with demoralization at .34 (p<.0001). Conclusion. This lack of association between AIDS deaths and depressive symptoms may reflect a capacity for adaptive "habituation" to certain types of loss among high risk groups.

W.B.O.42

NEUROLOGICAL AND NEUROPSYCHOLOGICAL DEFICITS IN 240 HIV - SEROPOSITIVE HEMOPHILIACS IN WR 2 - 6

Riedel,Rolf-Rainer *, Clarenbach P.*, Bülau P.**, Helmstadter Ch.**, Brackmann H.-H.***, Niese D.****, Bruzki Ch.*, Wirtz K.*
* Dept. of Neurology , ** Dept.of Epileptology , *** Institut of Hematology , **** Dept. of Medicine ; University Clinic , 5300 Bonn , West - Germany

We present the data of 240 HIV - seropositive hemophiliacs and 30 HIV - negative hemophiliacs as controls . According to the criteria of WALTER REED (WR) the patients were staged : 105 pat. as WR 2 , 44 as WR 3 - 5 , 22 as WR 6 . The examination program covered a neurological status , an EEG - analysis and a neuropsychological test - battery (AVLT , MWTB , CI , Benton , d-2 , v. Zerssen , BFS) .
In WR 6 patients we saw a statistical significance (p o.o5) for the following neurological deficits : polyneuropathy , subacute encephalitis , lesions of the Fasc. gracilis / cuneatus . A significance were found in EEG for focal activity and diffuse slowing in WR 6 patients . Also in these patients we observed a left hemispheric deficit in verbal memory (significance p o.o5) . By tendency we found comparable data for WR 5 patients . Only in some cases we found a correlation between the neuropsychological and the EEG - data .
Our data suppose only a statistical significance for neurological , neuropsychological and EEG - data in WR 6 patients - but these results have still to be proved for WR 5 patients .

W.B.O.43

SLOWED COGNITIVE PROCESSING IN HIV+ PATIENTS IN COMPARISON TO PSYCHIATRIC CONTROLS

Martin, Alex; Kampen, D.; Salazar, A.M.; Williams, J.; Law, W.; Roller, T.; & Walter Reed Retrovirus Research Group.
Uniformed Services University of the Health Sciences & Henry M. Jackson Foundation, Bethesda, Maryland; Walter Reed Army Medical Center, Washington, DC, USA.

Objective. To investigate cognitive decision time in HIV+ individuals.
Methods. Fifty (50) HIV+ individuals referred for neuropsychological testing and 15 seronegative patients with adjustment disorders (ADJ DIS) were tested on simple (SRT) and choice (Go: No-Go) visual reaction time tasks. Patients were classified in Walter Reed Stages 1-5; the majority had persistent lymphadenopathy (WR-2, 52%); 84% were in WR Stages 1-3. The ADJ DIS patients were matched with the HIV+ group on education, depression, anxiety, and number of recent stressful life events.
Results. The HIV+ patients were significantly slower than the ADJ DIS controls on both the simple and choice reaction time tasks (p<.01). Moreover, the HIV+ patients displayed significantly delayed decision time (choice minus SRT) in comparison to the controls (103 vs. 65 msec). This same difference held when the groups were equated for SRT by eliminating the scores of 11 HIV+ patients with SRTs outside the range of controls. Failures to inhibit response rarely occurred in either group.
Conclusions. Relatively asymptomatic HIV+ patients may exhibit slowing of cognitive processing that cannot be attributed to depression or anxiety. Similar findings have been reported in patients with "subcortical" dementia (e.g., progressive supranuclear palsy), and may be one of the earliest manifestations of HIV+ related cognitive dysfunction.

W.B.O.44

NEUROPSYCHOLOGICAL CHANGE ON LONGITUDINAL ASSESSMENT: PREVALENCE AND PATTERN IN HIV SPECTRUM DISORDERS

Temoshok, Lydia; Drexler, M.; Canick, J.P.; Sweet, D.M. and Hollander, H. University of California School of Medicine, San Francisco, CA., U.S.A.

Objective. Recent interest has focused on the course of cognitive and memory problems that may be manifested in HIV infection. This study explored the prevalence and pattern of change over 1.5 years on a variety of neuropsychological measures in men with HIV spectrum disorders.
Methods. 103 seropositive homosexual men with at least one HIV-related symptom were recruited from the UCSF AIDS Clinic and administered neuropsychological screening batteries, in addition to psychosocial self-report and interview measures, at 3 time points about 6 months apart. A subset of 66 subjects had neuropsychological data available for both Times 1 and 2.
Results. Unexpectedly, the group as a whole showed improved neuropsychological functioning from Time 1 to 2. The neuropsychological status of 25 Ss improved without declining in any area, while 26 Ss showed mixed, mild changes over time, and 15 declined without showing any improvement. Most measures of distress decreased over time, and scores on anxiety decreased significantly. However, there were no significant group-mean differences on measures of depression or anxiety between those who improved and those who declined in neuropsychological status. Surprisingly, neither improvement nor decline was related to the use of AZT.
Conclusion. While 23% of our sample showed clear evidence of neuropsychological decline over time, 38% of those retested showed notable improvement. These results suggest that neuropsychological functioning in some patients may not show a pattern of inexorable decline. These findings have important implications for assessments and interventions with HIV patients.

W.B.O.45

FURTHER EVIDENCE OF LACK OF HIV-1 RELATED COGNITIVE IMPAIRMENT DURING THE ASYMPTOMATIC STAGES: THE MULTICENTER AIDS COHORT STUDY (MACS).

Selnes, Ola A.*; McArthur, J.C.*; Miller, E.N.**; Sheridan, K.***; Becker, J.T.**** Gordon, B.*; Multicenter AIDS Cohort Study, *Johns Hopkins Medical Institutions, Baltimore, MD, **UCLA Neuropsychiatric Institute, Los Angeles, CA, ***Northwestern University, Chicago, IL; ****University of Pittsburgh, Pittsburgh, PA, USA

Objective: To determine the prevalence of cognitive abnormalities among asymptomatic HIV-1 infected men (CDC Groups II/III) using comprehensive neuropsychological (NP) testing.
Methods: Participants in the Multicenter AIDS Cohort Study (MACS) Neuropsychological study were referred for comprehensive NP testing either as controls or because they previously had tested positive on either a NP screening test or a standardized neurological questionnaire. The NP testing included the Shipley Hartford Scale, Block Design (WAIS-R), Rey Complex Figure, Warrington Recognition Memory, Trails A & B, and the Paced Auditory Serial Addition Test. Participants with a diagnosis of ARC or AIDS were excluded from this analysis. The effects of azidothymidine were not analyzed separately.
Results: Analysis of data from 181 seronegative (SN) and 225 seropositive (SP) men showed no difference in age, education, handedness, ETOH or drug use between the serostatus groups. Comparison of group means revealed no significant differences in performance between SN's and SP's on any of the NP measures. Less than 10% of the SP's had abnormal performance on individual subtests (2 SD's below mean for SN's), which did not differ significantly from SN's.
Conclusions: These findings provide additional evidence, using more comprehensive testing, that the prevalence of NP abnormalities in otherwise healthy HIV-1 infected homosexual men is low, and not different from uninfected SN controls. These results confirm our previous conclusions based on initial NP screening of healthy HIV-1 infected men in the MACS cohort.

THE ROLE OF THE PHARMACEUTICAL INDUSTRY IN DRUG AND VACCINE DEVELOPMENT

Petricciani, John C.
Pharmaceutical Manufacturers Association, Washington, DC, USA

The pharmaceutical industry has responded to the need for various strategies to intervene in the HIV global epidemic in a remarkably broad and rapid manner. Diagnostics became available within a year of the discovery of HIV as the etiologic agent, the first drug was approved only three years later, as was the first vaccine clinical trial. At the present time, there are over 50 companies involved in the development of over 60 medicines for the treatment or prevention of HIV infection.

Clinical trials remain the single most important means of assessing the actual safety and efficacy of new medicines, and the pharmaceutical industry has been working cooperatively with governmental organizations and others to evaluate potentially useful new agents. While there have been problems in the implementation of programs, the overall model of government/industry cooperation in the development of HIV-related medicines is one which PMA member companies support. Specific suggestions for improving the working relationship among industry, government, clinical research centers, and patients will be made.

W.B.0.47

Clinical Trials in AIDS: The Regulatory Perspective,
Ellen C. Cooper, Director, Division of Antiviral Drug Products, U.S. Food and Drug Administration, Rockville, Maryland, U.S.A.

FDA, in its regulatory role, is a major player in new drug development in the U.S.A. This role has become more intensive and extensive in AIDS drug development, as outlined in new interim regulations (21 CFR 312 Subpart E). From the scientific/regulatory perspective, three issues have been most problematic in the design and conduct of clinical trials in AIDS. The first issue stems from constraints on the choice of the most appropriate control group, whether placebo, no treatment, dose comparison, active, or historical control. A second major issue is selection of primary outcome measures on which decisions regarding efficacy should be made, particularly for new antiretroviral agents. A beneficial impact on important clinical endpoints is required to demonstrate efficacy of a new drug in most diseases. In the case of complex, chronic, life-threatening diseases such as AIDS, pressure builds rapidly to substitute near-term, "harder" clinical endpoints. The third major issue is timing of access to experimental drugs by patients with life-threatening diseases. The individual's "right" to try a new drug very early in development may conflict with society's need to determine systematically which drugs are safe and effective, and which are not. If appropriate and well-designed, randomized controlled trials (RCT) are not conducted during the "window of opportunity" following the demonstration of preliminary safety and activity, but before widespread use makes RCT difficult to perform because of the presumed but not proven efficacy of the drug, therapeutic advances in the treatment of AIDS will be delayed if not lost.

PATIENTS PERSPECTIVE

Paul Leblanc

W.B.0.51

ETHICS AND CLINICAL TRIALS
Robert J. Levine, Yale University School of Medicine, New Haven, CT, USA

The randomized clinical trial (RCT) is the gold etnadard for establishing the validity of medical therapies. RCTs must be conducted in accord with established ethical norms including: There should be a) sound scientific design, b) competent investigators, c) a reasonable balance of risks and benefits, d) informed consent, and e) equitable selection of subjects. This presentation is an overview of some of the more difficult ethical problems encountered by clinical trialists. Must subjects be informed that their therapy has been selected by chance? What should they be told about preliminary data and about alternatives to participation in the RCT? What is the role of the null hypothesis (or clinical equipoise) in the ethical justification of the RCT? Are placebo controls justified when subjects have lethal diseases? Is participation in a RCT a burden or a benefit? Should vulnerable populations be protected from the burdens of participation or assured access to the benefits of participation in RCTs? In what circumstances should alternative designs -- e.g., historical controls -- be considered? Satisfactory answers to such questions require careful consideration of the relevant facts about particular RCTs and prospective subject populations.

Thérapie : la ribavirine et les autres médicaments anti-VIH
Therapy: Ribavirin and Other Anti-HIV Drugs

Th.B.O.1 PHASE I TRIAL OF ORAL RIBAVIRIN IN HIGH RISK PATIENTS FOR AIDS

Roberts, Richard B.*; Malouch, R.**; and Jurica, K.*.
*Cornell University Medical College, New York, NY, USA;
**Yale University School of Medicine, New Haven, CT, USA;

Objective. To determine tolerance and effect on virologic and immunologic surrogate markers with escalating doses of oral ribavirin in homosexual men.
Methods. Two groups of eight men each received either 1200 or 1600 mg ribavirin daily for 12 weeks (Grps A and B respectively). An additional 15 men who had received maintenance ribavirin 800 mg daily for 44-52 weeks also received similar escalating doses for 20 weeks (Grp C). Within and between group comparisons were made in the analysis of per patient changes from baseline over time.
Results. Clinical adverse reactions occurred in 17 of 31 and anemia and reticulocytosis in all subjects. No reduction in HIV activity (antigen capture assay or serum p24 antigenemia) nor significant immunologic enhancement (serum beta-2 microglobulin levels, antigen-induced proliferation or gamma interferon production)were noted. Lymphopenia affecting all subsets occurred at both daily dosing but was more pronounced in Grp B.

	8 week-Baseline			12 week-Baseline		
Within Group	CD4	CD8	CD2	CD4	CD8	CD2
Grp A (p value)	-24(.08)	0(.57)	-177(.11)	-48(.02)	-35(.94)	-146(.29)
Grp B (p value)	-132(.02)	-448(.02)	-642(.02)	-134(.07)	-308(.02)	-377(.02)
Between Group						
Grp AvsB-p Value	0.60	0.02	0.15	0.95	0.01	0.09

Similar results were observed in Grp C subjects.
Conclusions. Oral ribavirin 1200 or 1600 mg daily for 12-20 weeks had no enhanced effect on virologic or immunologic surrogate markers. Lymphopenia was observed in all treatment groups and was more marked in those subjects receiving 1600 mg daily.

Th.B.O.2 PHASE I/II TRIAL OF RIBAVIRIN + ISOPRINOSINE IN ASYMPTOMATIC HIV VIREMIC GAY MEN

Schulof, Richard*; Simon, G.*; Parenti, D.*; Sztein, M.*; Meyer, W.**; Paxton, H.**; et al.
*George Washington University Medical Center, Washington, DC, USA; and
**Maryland Medical Laboratory, Baltimore, Maryland, USA.

Objective: To assess the safety, toxicity, clinical, immunologic and anti-viral effects of this oral 2-drug combination administered daily for up to 3 months.
Methods:
Subjects: HIV culture-positive (x2) gay men, CDC Groups II or III, CD4 counts (x3) between 150-400 mm³.
Treatment: Isoprinosine: 4 gm (1 gm QID)/day, all men.
Ribavirin: ARM A - 1200 mg(400 mg TID)/day x5, then 800 mg/day.
ARM B - 1200 mg/day.
Results: Five of 9 men on ARM A & 5 of 6 men on ARM B have completed at least 2 months of treatment. No clinical toxicities or HIV-related events were observed. Treatment was associated with a generalized lymphopenia affecting all lymphocyte subsets including CD4. Major pre- and 2-3 month post-treatment results are:

		# HIV-CULT. POS.	MEAN TIME (DAYS) TO POS. CULT.	MEAN CD4/mm³	MEAN % CD4	MEAN CD4/CD8
ARM A	pre-rm	5	10.8±1.0(SEM)	330±17]p<.01	21±3	0.42±0.09
(n=5)	post-rm	5	9.6±1.1	214±18	21±3	0.39±0.08
ARM B	pre-rm	5	12.8±1.6]p<.05	336±32]p<.10	24±3	0.49±0.10
(n=5)	post-rm	5	7.6±0.5	242±27	28±4	0.54±0.13

Three men in ARM A were p24 antigenemic, and levels did not change on treatment. On serial monitoring (Q month) no improvements were noted in DTHS skin reactivity, in in vitro lymphoproliferative responses [to mitogens, alloantigens, and soluble antigens], or in NK activity.
Conclusion: Although well-tolerated at the doses and schedule employed, the combination of ribavirin and isoprinosine did not result in HIV-suppressive or in immunorestorative effects. (Supported by NIAID, NIH, Cooperative Agreement No. 1U01-AI25867).

Th.B.O.3 2',3' DIDEOXYCYTIDINE (DDC) IN THE TREATMENT OF PATIENTS WITH AIDS AND ARC

Gottlieb, Michael,* Galpin, J.,* Thompkins, J.,* Wilson, D.** Donatacci, L.,** Soo, W.,**
*Porton Medical Group, Sherman Oaks, CA, USA **Hoffmann-La Roche, Nutley, NJ, USA

Objective: To evaluate tolerance and antiviral activity of dideoxycytidine (ddC) in a multiple dose study in patients with AIDS or ARC.
Methods: Twenty-one patients with AIDS or ARC with p24 antigen > 70 pg/ml and T4 cells < 400 cells/mm³ received ddC orally at a dose of either 0.03 mg/kg once a day or 0.01 mg/kg every 8 hours for 24 weeks. P24 antigen, T4 counts and toxicity parameters were monitored.
Results: At 0.03 mg/kg, mild peripheral neuropathy was reported in 3 of 11 patients between weeks 8 & 17. At 0.01 mg/kg, no cases of peripheral neuropathy were noted. Other adverse experiences included mild dyspepsia and nausea. 2 of 8 patients who received 0.03 mg/kg had > 50% decrease in p24 antigen at the end of therapy, as compared to 9 of 9 patients who received 0.01 mg/kg. Of these nine, 4 had a > 70% reduction. T4 counts in the majority of patients either remained constant or rose transiently. No clear trend was observed in cutaneous delayed type hypersensitivity, weight and Karnofsky scores. No significant bone marrow toxicity was observed with either dosing regimen.
Conclusion: ddC at low doses was well-tolerated. Different dosing schedules and regimens demonstrated a different degree of antiviral activity. The 0.01 mg/kg regimen was most effective. Further study to evaluate ddC long-term safety and efficacy using clinical endpoints is warranted.

Th.B.O.4 ESCALATING DOSE PHASE I STUDY OF INTRAVENOUS AND ORAL 2',3'-DIDEOXYINOSINE (DDI) IN PATIENTS WITH AIDS OR ARC

Yarchoan, Robert; Thomas RV, Pluda JM, Hartman NR,, Mitsuya H, Perno CF, Johns DG, and Broder S.
Clinical Oncology Program, National Cancer Institute, NIH, Bethesda, MD, USA

Objective. Two pyrimidine drugs with activity against HIV, AZT and ddC, belong to the dideoxynucleoside (ddN) family. In this study, we report a Phase I trial of ddI, a purine ddN analog.
Methods. 20 patients with AIDS or ARC were given 2 weeks of ddI IV, followed by 4 or more weeks of oral dosing (given with antacids) at twice the IV dose. Six dosing regimens were tested, ranging from IV doses of 0.2 mg/kg every 12 hr to 1.6 mg/kg every 8 hr.
Results. Oral bioavailability (given with antacids) was 35%, and ddI penetrated into the CSF. Two pts dropped out at 1 wk (1 because of *Cryptococcal* meningitis and1 for personal reasons); the other 18 completed 6 or more wks of dosing. One pt (also on TMP/SMX) developed neutropenia after 20 wks, one pt developed a morbilliform rash, and some pts reported some difficulty sleeping or irritability; otherwise, toxicity was minimal. No macrocytosis was seen. No anti-HIV response was seen at the lowest dose; however, the 15 evaluable pts on the 5 higher doses showed evidence of an anti-HIV effect. In these pts, the T4 count increased from 141±25 at entry (mean±SEM) to 226±43 at wk 2 (p<0.001) and 193±37 at wk 6 (p<0.01 c/w entry). All 7 pts with detectable serum HIV p24 antigen (Ag) at entry had a decline by wk 2 (116±97 pg/ml at wk 2 vs. 191±49 at entry; p<0.02). Six of these 7 pts sustained the drops in p24 Ag at wk 6. Four anergic pts developed delayed type hypersensitivity reactions by wk 6; 4 pts had increased *in vitro* proliferative responses to soluble Ag. The pts generally had increased energy and gained a mean of 2 kg wt.
Conclusion. In short term testing, ddI appears to be an oral anti-retroviral agent with significant clinical activity but with minimal toxicity.

Th.B.O.5 PHARMACOKINETIC STUDIES OF RECOMBINANT SOLUBLE CD4 IN PATIENTS WITH AIDS AND AIDS RELATED COMPLEX

Kahn, James*; Davis, AJ**; Groopman J**; Kaplan, L*, Sherwin, S***; Volberding, PA*
*University of California San Francisco, San Francisco, California, USA. **New England Deaconess Hospital, Harvard Medical School, Boston, MA, USA. ***Genentech Inc, South San Francisco, CA, USA

Objective. To describe the pharmacokinetics of intravenous bullous injection of recombinant soluble CD4 in patients with AIDS and ARC.
Methods. Patients with AIDS and ARC, T-cells <400 and normal hematologic and serum chemistries were enrolled in this study. One intravenous line was placed for pharmacokinetics; a second intravenous line was placed in each patient for drug administration. Soluble CD4 was administered over 2 to 3 minutes by slow intravenous push. Pharmacokinetic studies were drawn at 10, 20, 30, 45, 60, and 90 minutes as well as 2, 3, 4, 6, 8, 12, 16, and 24 hours post-infusion. Pharmacokinetic studies were performed on days 1 and 56. The analysis for CD4 was performed using two monoclonal assay system.

Results.	Dose	N (patients)	Duration (Hours)	Peak ng/ml
	1 ug/kg	6	1.5-4	17-43
	10 ug/kg	10	2-6	100-480
	30 ug/kg	8	8-24	400-1250

Conclusions. Recombinant soluble CD4 given in intravenous bullous can be detected from 1.5 to 4 hours after administration at a dose of 1 ug/kg and the peak is 12-43 ng/ml. At 10 ug/kg the peak is 100-480 ng/ml. At 30 ug/kg the peak is 400-1250 ng/ml. Doses at 100 ug/kg and 300 ug/kg are being analyzed and IV subcutaneous and intramuscular doses have begun. Recombinant soluble CD4 can be detected in the serum in patients with AIDS and ARC. Increased dose of CD4 will increase the peak concentrations and the duration of CD4 detection.

Th.B.O.6 ESCALATING DOSE TOLERANCE TRIAL OF RECOMBINANT SOLUBLE CD4 IN HUMANS

Schooley, Robert*; Ho, D**; Gaut, P**, Tierney, M*; Schindler, J***; Henochowicz, S**** et al. *Mass. Gen. Hosp., Boston, MA, USA, **Cedars-Sinai Medical Center, Los Angeles, CA, USA, ***Biogen, Inc., Cambridge, MA, USA and ****NIAID AIDS Program, Bethesda, MD, USA.

Objective. To study the safety and pharmacokinetics of recombinant soluble CD4 (rsCD4) when administered to humans by intramuscular or intravenous routes.
Methods. We performed an escalating dose tolerance trial of rsCD4 (Receptin) in which daily doses of 1 to 30mg rsCD4 were administered to a group of patients with AIDS or AIDS related complex who were preselected for the absence of antibodies to rsCD4. Patients were followed for adverse clinical and laboratory events during the 28 day dosing period. Pharmacokinetics of rsCD4 were determined after intravenous and intramuscular administration. Antiviral activity of rsCD4 was assessed by serum p24 antigen determination, and quantitative HIV-1 cultures obtained from peripheral blood mononuclear cells and plasma.
Results. rsCD4 was well tolerated when administered by the intramuscular or intravenous routes. No significant changes in hematologic, hepatic, or renal function were observed. No antibodies to rsCD4 were detected following therapy. Pharmacokinetics of rsCD4 following intravenous and intramuscular administration, and immunologic and antiviral efficacy parameters will be presented.
Conclusion. rsCD4 is well tolerated by humans receiving the drug for periods of up to one month.

Test de dépistage par réaction en chaîne des polymérases
PCR Diagnostic Test

Th.B.0.7

A METHOD FOR QUANTITATING RELATIVE AMOUNTS OF HIV PROVIRAL SEQUENCES IN PBMCS BY THE POLYMERASE CHAIN REACTION (PCR)

Shirley Kwok, D. Kellogg, J.J. Sninsky
Department of Infectious Diseases, Cetus Corporation, Emeryville, CA. USA

Objective. To quantitate by the polymerase chain reaction, the amount of HIV proviral DNA sequences present relative to the total amount of input DNA in a sample. The availability of such an assay will allow the monitoring of proviral load during the natural history of infection and during various therapeutic regimen.
Method. Human placental DNA was spiked with known copies of HIV molecules and coamplified in the presence of a primer pair that amplifies a 130 bp fragment of HIV-1 and a primer pair that amplifies a 242 bp cellular sequence; HLA-DQα. Amplified products were detected by autoradiography following hybridization with HIV and HLA kinased probes and separation by polyacrylamide gel electrophoresis. Because of differences in size, the amplified products can be differentiated. To quantitate the amount of each product, the gels were scanned with a radioanalytic system. Standard curves were generated by plotting the amount of HIV and HLA products produced against known amounts of each target present prior to amplification. By extrapolating from the standard curves, the relative amount of HIV targets in a given sample was determined.
Results. By altering the ratio of HIV and HLA primers, we were able to simultaneously amplify both sequences without compromising the HIV signals. We demonstrate that 10-800 molecules of HIV can be quantitated after 30 cycles of amplification, 200-3200 molecules with 25 cycles, and 3200-51,800 molecules with 20 cycles of amplification
Conclusion. We demonstrate in model studies that HIV and HLA sequences can be quantitatively co-amplified. In addition, a quantitative readout was obtained for both sequences. Results describing extension of these studies to cell lines and patients on antiviral therapies will be presented.

Th.B.0.9

EVALUATION OF THE POLYMERASE CHAIN REACTION (PCR) IN A WELL CHARACTERIZED COHORT OF HOMOSEXUAL AND BISEXUAL MEN: PCR-POSITIVE, HIV-ANTIBODY NEGATIVE RESULTS ARE RARE

Lifson, Alan R.*; Stanley,M.**; O'Malley,P.*; Pane,J.**; Jeffery,B.**; Rutherford,G.*; Sohmer,P.**. *Department of Public Health, San Francisco, CA; **Pathology Institute, Berkeley, CA, USA

Objectives: To evaluate PCR for HIV DNA in a cohort of homosexual and bisexual men whose clinical and HIV-antibody (Ab) status is known.
Methods: We conducted blinded PCR testing on frozen lymphocytes from 167 men participating in prospective studies of HIV infection. Thirty cycles of amplification were conducted, followed by detection with probes corresponding to two gag primers; each primer/probe assay was run in duplicate. A positive result was defined as repeat (2/2) detection of HIV DNA by at least one of the two primer/probe pairs. HIV-Ab testing was performed using ELISA and (if repeatedly reactive) IFA assays.
Results: PCR was negative for 101/102 (99%) HIV-Ab negative men. The one PCR-positive Ab-negative sample was PCR negative on repeat testing; a second specimen drawn from the same man 8 months later was also PCR and HIV-Ab negative, suggesting the first PCR result was a false positive. PCR was positive in 63/65 (97%) HIV-Ab positive men, including 7/7 persons with AIDS, 19/19 with AIDS-related conditions, 11/11 with asymptomatic generalized lymphadenopathy and 26/28 men without signs or symptoms of HIV-infection. Overall, the PCR and HIV-Ab were in agreement on 164/167 (98%) specimens.
Conclusions: The PCR assay, using this technique and in this population, has an excellent concordance with the HIV antibody test. Antibody-negative, PCR positive results for HIV were very uncommon.

Th.B.0.11

SIMULTANEOUS DETECTION OF HTLV-I OR HTLV-II IN AIDS PATIENTS BY PCR

De, Barun and Srinivasan, A., Centers For Disease Control, Retrovirus Diseases Branch, Atlanta, Georgia, USA

Objective: To identify the nature of human T-cell lymphotropic virus infection in AIDS patients which might be complicated by the presence of other opportunistic viruses viz. Herpes, Hepatitis, etc.
Methods: High molecular weight DNA was extracted from the cells derived from AIDS patients. Polymerase chain reaction was performed using the specific sets of primer pairs (for HTLV-I: pol primer pair at positions 3015-3034 sense strand and 3154-3134 antisense strand with probe at position 3050-3074; HTLV-II: pol primer pair at positions 2989-3010 sense strand and 3131-3110 antisense strand with probe at position 3026-3049; HIV-I: gag primer pair at positions 1551-1578 sense strand and 1665-1638 antisense strand with probe at position gag 1595-1635). The amplified products viz. 140, 143 and 115 base pairs corresponding to HTLV-I pol, HTLV-II pol and HIV-I gag genes were separated on a 3% polyacrylamide gel and then characterized by the Southern blot hybridization using specific viral probes.
Results: We have employed the polymerase chain reaction to distinguish HTLV-I and HTLV-II. Cells derived from an African AIDS patient had HTLV-I proviral sequences and cells from a hemophiliac from North America showed HTLV-II proviral sequences in addition to HIV sequences.
Conclusion: Multiprimers PCR provides a sensitive, accurate and quicker method to distinguish the related T-lymphotropic retroviruses.

Th.B.0.8

COMPARISON OF PCR ANALYSIS AND CULTURE IN THE DETECTION OF HIV-1 INFECTION IN HEMOPHILIACS

Jackson, Brooks*; Sannerud K*; Kwok S**; Sninsky J**; Hopsicker J*; Balfour HH Jr*. *U of Minnesota, Mpls., MN, **Cetus Corp., Emeryville, CA, USA.

Objective. To compare the sensitivity and specificity of an HIV-1 polymerase chain reaction (PCR) assay with an HIV-1 culture method in testing HIV-1 antibody-positive and antibody-negative hemophilia patients.
Methods. PCR analysis was performed on the PBMC DNA from 59 HIV-1 antibody-positive and 20 antibody-negative hemophilia patients. A gag primer pair [SK 38 (1551-1578), SK39 (1637-1665)] and Taq polymerase was used to amplify a 115 base fragment over 30 cycles. Cycle time and temperatures were as follows: denaturation 25s - 95°C, reannealing 25s - 55°C, chain elongation 60s - 72°C. The amplified HIV-1 sequence was then detected by autoradiography after liquid hybridization with a ^{32}P-labelled probe [SK19 (1596-1635)] and gel electrophoresis. HIV-1 cultures were performed by cocultivating 1 X 10^7 patient PBMC with 5 X 10^6 PHA stimulated donor PBMC in the presence of RPMI-1640, 20% fetal calf serum and 5% IL-2 at 37°C/5% CO_2 and assaying for the presence of HIV-1 p24 antigen every 3 days for up to 42 days.

Results.	HIV-1 Ab Positive	HIV-1 Ab Negative
HIV CULTURE +	57/59 (97%)	0/20 (0%)
HIV PCR +	57/59 (97%)	0/20 (0%)

The two culture negative antibody-positive subjects were PCR positive and the two PCR negative antibody-positive subjects were culture positive. Therefore, all 60 HIV-1 antibody-positive subjects had direct evidence of HIV-1 infection by either PCR or HIV-1 culture or both.
Conclusion. Both HIV-1 culture and PCR analysis have comparable sensitivities (97%) and excellent specificity (100%) in the detection of HIV-1 infection.

Th.B.0.10

DETECTION OF HIV-1 DNA IN PERIPHERAL BLOOD BY POLYMERASE CHAIN REACTION (PCR) AND NON-RADIOACTIVE OLIGONUCLEOTIDE PROBES.

Adler, Karl E*; Bechtel, LJ**; Conway, B**; Kaplan, JC** and Hirsch, MS**.
*Dupont Medical Products, Billerica, MA, USA **Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA.

Objective. To detect HIV-1 DNA directly in peripheral blood mononuclear cells (PBL) by PCR and hybridization with a non-radioactive probe.
Methods. An oligonucleotide probe covalently linked to alkaline phosphatase has been used to detect HIV-1 sequences in DNA amplified by PCR. PBL (3-5 x 10^6) were isolated by Ficoll Hypaque sedimentation, lysed in a solution of 1.0% Triton-X-100, 10 mM Tris-HCl, pH 7.5, 1.0 mM EDTA and boiled for 10 minutes. Two oligonucleotides flanking a conserved region of the HIV-1 pol gene (BRU isolate;1934-2212) were used as primers. Samples were subjected to 30-50 cycles of amplification. Products were detected by slot blot hybridization using the enzyme-linked probe.
Results. HIV-1 DNA was detected in PBL from 20/23 (87%) seropositive individuals (CDC Groups II-IV). Samples from 8/8 individuals negative for serum p24 antigen but positive following coculture, were positive for HIV-1 DNA by this technique. DNA amplified from PBL of seronegative individuals was negative for HIV-1 as were samples from cells infected with HTLV-1, HSV-1 or CMV.
Conclusion. This sensitive non-radioactive method for detecting HIV-1 proviral DNA ,combined with improved sample processing, should be valuable in clinical and research settings.

Th.B.0.12

A MICROTITER BASED DNA SANDWICH ASSAY FOR THE DETECTION OF HIV-1 IN CLINICAL SAMPLES

George Keller, D.P. Huang, L. Jagodzinski, C. Overholt, D. Petersen, and M. Manak. Biotech Research Laboratories Rockville, MD 20850 USA

Objectives: A microtiter based DNA sandwich hybridization assay was used to detect HIV-1 sequences in clinical samples following amplification with Polymerase Chain Reaction (PCR).
Methods: DNA was extracted from peripheral blood lymphocytes from HIV-1 seropositive individuals and normal blood donors. It was then subjected to PCR amplification using specific primers in the HIV-1 gag region. The amplified product was hybridized in microtiter plates which contained covalently attached capture DNA sequences. A biotin labeled probe adjacent to the capture sequence was used to detect specific hybridization. Following incubation with a peroxidase-streptavidin conjugate and a colorimetric substrate, the amount of hybridization was quantitated spectrophotometrically. All samples were also analyzed by Southern blotting using ^{32}p labeled HIV-1 probes. Specific hybridization was quantitated by cutting out the hybridized bands and counting in a scintillation counter.
Results: Using serial dilutions of HIV-1 infected cells with uninfected cells, the Optical Density after hybridization was proportional to the amount of virus present in the sample. When the OD was off scale, dilutions of the amplified product could be performed to give a quantitative result. This test could detect 3-5 HIV-1 infected cells in 10^6 uninfected cells, or about 10-15 molecules of HIV-1 DNA. DNA from a total of 164 clinical samples was amplified by PCR and the amplified product tested by both the sandwich and the Southern Blot assays. Complete agreement between the DNA sandwich and the ^{32}p Southern Blot results was observed.
Conclusion: The sandwich hybridization format provides a convenient, rapid and sensitive analysis of the PCR product using a non-radioactive system. Using the microtiter wells, up to 96 samples can be tested at the same time. This format is compatible with existing plate handling equipment and will permit this assay to be automated for use in clinical laboratories.

Infections respiratoires chez les consommateurs de drogues par voie intraveineuse
Respiratory Infection in IV Drug Users

Th.B.0.13

PNEUMONIES BACTERIENNES ET VIRALES AU COURS DU SIDA CHEZ LES UTILISATEURS DE DROGUE PAR VOIE INTRAVEINEUSE (IVDU). MOUTON Yves. CHIDIAC C., SENNEVILLE E. Service Régional des Maladies Infectieuses, Centre Hospitalier. F-59208 TOURCOING, FRANCE.

Le poumon est l'organe le plus souvent atteint au cours du SIDA et les pneumonies bactériennes (PB) ont longtemps été occultées par les infections parasitaires et virales. Les pneumonies constituent une menace vitale nécessitant une prise en charge rapide par le clinicien. L'incidence, la morbidité et la mortalité des PB sont significativement augmentées chez les IVDU infectés par le VIH qui cumulent différents facteurs de risque : (I) Le déficit des fonctions lymphocytaires (T mais également B) et macrophagiques majorant le risque d'IPB à Mycobactéries, Nocardia, Legionella et germes encapsulés (S. pneumoniae, H. influenzae, B. catarrhalis). (II) Les endocardites et septicémies à point de départ thrombophlébitique exposant aux embolies pulmonaires septiques (S. aureus, isolé dans plus de 50% des cas, posant le problème de sa résistance en relation avec "l'écologie des shooting galleries"). (III) Les troubles de conscience et le mauvais état buccodentaire favorisant les pneumonies d'inhalation.

L'imagerie médicale, les explorations invasives selon des algorythmes et l'isolement de l'agent pathogène conduisent facilement au diagnostic de PB mais la responsabilité du Cytomégalovirus est plus difficile à établir.

Les PB, plus accessibles à la thérapeutique que les pneumonies virales, posent un problème de récidive dont la prévention n'est pas codifiée (vaccination anti-pneumococcique ?).

Th.B.0.14

FUNGAL PNEUMONIA

Cargnel A.*; Costanzi G.*; Giannini V.**; Grillo L.**; Milazzo F.*; Narciso P.**; Moroni M.*; Visco Giuseppe**.
"L. Spallanzani" Hospital for Infectious Diseases, Rome**
Infectious Diseases Dept, University of Milan*, Italy.

Fungal pneumonias, although quite frequent, are seldom diagnosed intra-vitam as opportunistic infections. Among 306 consecutive autopsies, a fungal pneumonia was found in 20 cases (0,1%) but only in 15 patients (4,9%) this pulmonary disease had been clinically recognized.

In our country Cryptococcus neoformans, Aspergillus fumigatus and Candida spp are more frequently found as agents of opportunistic pneumonias in AIDS patients.

Given that a pulmonary localization is usually observed in patients with disseminated fungaemias, an haematogenous port of entry rather than the aerogenous one may be hypothesized for this complication.

The main clinical features of fungal pneumonias are described, and the possibility for an effective treatment for this complication -if early diagnosed- with fluconazole, amphothericin B and flucytosine is emphasized.

Th.B.0.15

MYCOBACTERIAL INFECTIONS IN HIV-POSITIVE IVDA
Stille W*, Brodt HR*, Koller-Lampert K*, Schulze-Werninghaus G*, Jakschik M**, Helm EB*
*Universitätsklinik Frankfurt, Zentrum der Inneren Medizin
**Universitätsklinik Frankfurt, Zentrum der Hygiene

Objective: To compare clinical pattern, course and frequency of active TB and MNT in HIV-positive (HIV+) iv drug addicts (IVDA) and pts not HIV-infected or from other risk groups.
Methods: At Frankfurt University Hospital (FUH), all TB/MNT pts have been retrospectively registered since 1973/1980. Since 1982, all HIV+ pts have been examined prospectively.
Results: Until 1984, 726 inpatients with TB (ca. 60/year) were treated. Of these, 2 homosexual pts had AIDS, and 2 pts were IVDA (HIV status unknown). None of the 78 pts with proof of MNT had AIDS or was IVDA. From 1982-88, 336 AIDS in- and outpatients (31 IVDA = 9.2%) were treated at FUH. Of 50 HIV+ TB pts, 11 were IVDA. TB was diagnosed before any other AIDS manifestation in 10 out of 11 IVDA, but only in 2 of 39 pts from other risk groups. In IVDA, clinical pattern and course of TB (4x disseminated, 2x lymph nodes, 5x lungs) were more severe than in pts from other risk groups. Of 75 pts with MNT infections, 7 (= 9.3%) were IVDA. Compared to pts from other risk groups, range of pathogens, frequency and clin. course in IVDA did not significantly differ.
Conclusion: Active TB and other MNT infections are significantly more frequent in HIV+ than in HIV-neg. IVDA. Compared to HIV+ pts from other risk groups, IVDA develop TB earlier, more frequently, and with more severe clinical course. MNT infections in IVDA do not differ from those in pts from other risk groups.

Th.B.0.16

PCP AND DRUG ABUSERS: THE BRONX LEBANON HOSPITAL EXPERIENCE
Ernst, Jerome A.

Bronx Lebanon Hospital Center, Bronx, New York, United States.

Bronx Lebanon Hospital Center has been seeing AIDS patients since 1980. In 1988, over 6% of its patient population not admitted for infectious reasons tested HIV+ in a discarded blood survey conducted with the CDC. A sample of 364 males aged 25-44 showed that 68 (18.7%) with an admitting diagnosis not associated with HIV disease tested HIV positive.

A review of all available cases of drug abusers or their sexual partners that were bronchoscoped will be presented and features of those with PCP will be compared with those who were PCP negative.

Neurologie
Neurology

Th.B.0.19 AUTOANTIBODIES IN HIV-RELATED PERIPHERAL NEUROPATHY

Stricker, Raphael*; Dale, D.**; Wesley, A.**; Mahawar, S.**
*Department of Medicine, ** Department of Neurology, University of California, San Francisco, CA USA

Objective: To determine whether or not autoimmunity is involved in the pathogenesis of HIV-related peripheral neuropathy. Peripheral neuropathy is a common complication of HIV infection; between 35% and 60% of adult AIDS patients demonstrate abnormalities of the peripheral nervous system (PNS), depending on the method and time of evaluation. The mechanisms of the neuropathies remain unknown.

Methods: We performed immunoblotting using homogenates of normal human peripheral nerve. The blots were incubated with serum from HIV-infected or control subjects. Results: Serum antibody from 23 of 25 patients with HIV-associated neuropathies bound to a 25 kd protein in the nerve homogenates. The same sera were negative when incubated with human brain, rather than peripheral nerve, on immunoblots. Controls from 25 HIV-negative patients with and without neuropathy, and from AIDS patients without neuropathy, were negative ($p<0.001$), except in case (a patient with mononeuropathy multiplex and a history of drug use; further serological studies on this patient are pending).

Sequencing of the N-terminal 7 amino acids of the 25 kd PNS protein revealed identity (6/7) with a stretch of 7 amino acids of the HIV-1 pol polyprotein. Since there are 1.28 x 10^9 (20^7) different ways in which a stretch of 7 amino acids may be arranged, and the HIV-1 genome is less than 10 kilobases, the probability of this identity occurring by chance is less than 1 in 1000. Conclusion: Thus, it is possible that autoimmunity due to "molecular mimicry" may play a role in the pathogenesis of HIV-related peripheral neuropathy.

Th.B.0.21 STUDY OF NERVE BIOPSIES IN 36 PATIENTS WITH HIV INFECTION

Hauw, Jean-Jacques, Chaunu, M.-P. Ratinahirana, H. Hénin, D. Raphael, M., Léger, J.-M., Hôpital de La Salpêtrière, Paris, France.

Objective : To study the spectrum of changes on nerve biopsies in patients with peripheral neuropathy and HIV-1 infection.
Methods : Nerve and muscle biopsies were performed in 20 patients with distal symmetrical peripheral neuropathy (1 otherwise asymptomatic patient, 12 ARC and 7 AIDS), in 9 with acute or chronic inflammatory demyelinating polyneuropathy (3 otherwise asymptomatic patients, 4 ARC and 2 AIDS), in 5 with mononeuritis multiplex, (4 ARC and 1 AIDS), and in 2 with progressive polyradiculoneuropathy (2 AIDS).
Results. In inflammatory demyelinating polyneuropathies, segmental demyelination was, in most cases, associated with axonal degeneration as shown by quantitative study of teased nerve fibers. Conversely, in some cases of distal symmetrical polyneuropathy, segmental degeneration was associated with axonal degeneration. Mononuclear cell infiltrates composed mainly of Leu 2 (T8) positive cells involving frequently the walls of small vessels, especially venules (microvasculitis), were found nearly constantly in otherwise asymptomatic patients and ARC (20/24). They were very rare in AIDS patients (1/12) (Chi^2 : 18.51, $p < .00001$). They were not more frequent in inflammatory demyelinating polyneuropathy than in distal symmetrical peripheral neuropathy.
Conclusion. The presence of inflammatory infiltrates and of microvasculitis was more closely related to the stage of the HIV disease than to the type of neuropathy.

Th.B.0.23 MR IMAGING OF INTRACRANIAL MANIFESTATIONS OF AIDS: UNENHANCED AND GD-DTPA ENHANCED STUDIES

Henkes, Hans*; Schörner, W.*; Jochens, R.*; Iglesias, J.**; Ruf, B.***
and Felix, R.*.
*Departments of Radiology, **Neuropathology and ***Internal Medicine II, University Clinic Rudolf Virchow, Free University Berlin, W.-Germany

Objective. To determine the diagnostic value of unenhanced and Gd-DTPA enhanced MR imaging in the diagnosis of intracranial manifestations of AIDS. The sensitivity and specificity of CT and MR, both unenhanced as well as contrast enhanced, was determined.

Methods. 107 patients with proved HIV-1 infection, all of whom had CNS symptoms underwent a total of 142 MR examinations. CT (Somatom DR, plain and contrast enhanced scans) and MR studies (0.5T Magnetom; T2-WI: SE, TR 1600ms, TE 70ms; T1-WI: FLASH, TR 315 ms, TE 14 ms, $\theta=90^\circ$, unenhanced and after i.v. application of 0.1 mmol Gd-DTPA/kg(BW) were performed within a time interval of 15 days or less. Criteria for sensitivity were: detection of lesion (-s), number of detected lesions and delineation of lesion/edema /parenchyma. Specificity was assessed with respect to etiology and acuity of lesions.

Results: In 31/107 patients, CT and MR were negative. In 3 of these patients, a severe CNS manifestation (e.g. multiple subcortical necroses) was found at autopsy. 62/107 patients had positive CT and MR examinations. MR had a greater sensitivity than CT in 41 of these patients. Unenhanced T2-WI had a higher sensitivity than Gd-DTPA enhanced T1-WI. specificity, however, was significantly increased by the use of Gd-DTPA. 14/107 patients had a normal CT while MR demonstrated meningeal and/or parenchymal lesion (-s). Diagnosis of toxoplasmosis was established on the basis of lesion pattern, enhancing characteristics and follow up studies in 32/39 confirmed cases.

Conclusion: The excellent sensitivity of T2-weighted MR is only in some cases increased by Gd-DTPA enhanced T1-WI. Assessment of etiology and acuity of AIDS related intracranial lesions however requires contrast enhanced CT as well as MR imaging. With respect to specificity, CT and MR are complementary imaging modalities.

Th.B.0.20 ELECTROPHYSIOLOGICAL INVESTIGATION OF CENTRAL AND PERIPHERAL NERVOUS SYSTEM IN HIV-INFECTED PATIENTS.

Moglia, Arrigo*; Zandrini, C.*; Alfonsi, E.*; Sandrini, G.*; Bergonzoli, S.*; and Calderon, W.**
*Dept.of Clinical Neurophysiology and **3rd Dept.of Neurology, IRCCS C.Mondino; ***Dept.of Infectious Disease, IRCCS Policlinico S.Matteo, University of Pavia, 27100 Pavia, Italy.

Objective: Neurological disease often occurs in HIV-infected patients. Opportunistic infections and AIDS-dementia are major causes of CNS involvement; peripheral neuropaties, may also complicate this infection. Electrophysiological investigations offer the possibility to evidence early and/or subclinical involvement of both CNS and PNS.
Methods: 140 HIV infected patients (96/44=M/F), aged 18-50 yrs were studied:CDC Group II: n.62; Group III: n.38; Group IVA: n.13; Group IVB n.9; Group IVB-E n. 18. Motor and sensory conduction velocity (MCV/SCV), Sensory Evoked Potential (SEPs) and Central Conduction Time (CCT) were investigated.
Results: Abnormalities of MCV were observed ranging from 17% (group II) to 63% (IVB), while SCV and SEP were less frequently altered; CCTs were decreased from 47% (II) to 73% (IVB).
Conclusion: Our data demonstrate frequent involvement of CNS and PNS, particularly in AIDS and ARC patients, but also frequent in LAS and asymptomatic HIV positive groups; cortical stimulation seems to be the most sensitive method for an early detection of central motor pathways abnormalities.

Th.B.0.22 MORPHOLOGICAL FEATURES OF THE HIV-ENCEPHALITIS

Artigas, Juan; Niedobitek F.; Grosse, G.; Freund, K. and Heise, W.*
Department of Pathology and * Department of Medicine;
Auguste-Viktoria-Krankenhaus, Rubensstraße 125; 1000 Berlin 41, FRG.

Objective. To describe the neuropathological findings of the HIV-Encephalitis since previous studies are no conclusive.
Methods. 60 brains of HIV-infected patients were extensively examined with conventional histology, immunhistochemistry and electron microscopy.
Results. In 18 cases (30%) we found a HIV-Encephalitis. A extensive invasion of macrophages, microglia cells and multinucleated cells is present in all subcortical structures of the brain, predominantly in the frontal and temporal white matter. In all cases we found p24 and gp 41 positive macrophages (2-5%), multinucleated cells (5-10%), microglia cells (1-6%) and pericytes. Vacuolar leukoencephalopathy was also constant. Occasionally, we found macrophages in contact with neurons that show signs of degeneration. A strong gliosis with hypertrophia and hyperplasia of astrocytes is present in the white matter and in the midbrain. Calcifications are frequently seen. Pallor of the white matter is also a frequent finding, but only in 15 cases out of 18 a progressive diffuse leukoencephalopathy was found in celloidine slices. Clinically the patients suffer alterations of the personality to severe dementia.
Conclusions. HIV-Encephalitis is characterized by invasion of macrophages in the subcortical structures, some of them carrying HIV-antigen. These cells in contact with neurons produces degeneration and cell death. Strong astrogliosis, vacuolar and diffuse leukoencephalopathy are also main features.

Th.B.0.24 THE INTERVAL BETWEEN EQUIVOCAL AND DEFINITE NEUROLOGICAL SIGNS AND SYMPTOMS IN THE AIDS DEMENTIA COMPLEX (ADC)

Sidtis, John J; Thaler, H; Brew, BJ; Sadler, AE; Keilp, JG; Aranow, HA; and Price, RW. Memorial Sloan-Kettering Cancer Center, NY, USA

Objective. To estimate the time period between detection of equivocal and definite neurological signs and symptoms in a group of HIV-1 seropositive patients being followed for ADC.
Methods. 132 patients who were ADC Stage 0.5 (equivocal/subclinical ADC) (J Infect Dis, 158: 1079-1083, 1988) who underwent serial evaluations on the Neuro-AIDS Study Group neurological history, examination, and neuropsychological battery served as subjects in this study. The time to progress to a Stage 1.0 or greater (definite neurological signs and symptoms) was determined using Kaplan-Meier estimates.
Results. There was an average of 3.3 follow-up exams after the detection of equivocal/subclinical signs and symptoms, and the average follow-up time was 33 weeks. By 37 weeks, 25% of the patients had progressed to a stage 1 or greater; by 59 weeks, 50% of the patients had progressed. A preliminary analysis of possible predictive variables revealed no differential progression rate as a function of the presence or absence of eye-movement abnormalities or limb-slowing.
Conclusions. These data provide a preliminary estimate of the high rate of progression from equivocal/subclinical to functionally significant ADC. Additional experience will be required to identify clinical and laboratory findings which more accurately predict neurological progression.

Les lymphokines
Lymphokines

Th.B.O.25 DIFFERENCES IN IMMUNE ACTIVATION PARAMETERS DURING AND AFTER HIV SEROCONVERSION: SERUM β_2MICROGLOBULIN, NEOPTERIN, AND SOLUBLE IL-2R.

B HOFMANN, W CUMBERLAND, R DETELS, JL FAHEY. UCLA SCHOOLS OF MEDICINE AND PUBLIC HEALTH, LOS ANGELES, CA, U.S.A.

Objective. To describe cellular immune activation during and after HIV seroconversion.
Methods. Serum $\beta_2$microglobulin and neopterin are products and markers of cellular immune activation, whereas serum soluble interleukin-2 receptor (IL-2R) reflects only T cell activation.
Results. Fifty subjects investigated for $\beta_2$microglobulin before, during, and after HIV seroconversion showed an increase of this marker. The increase of $\beta_2$microglobulin appeared to reflect two distinct events in the immune activation since the primary increase correlated to the simultaneous increase in CD8 T cells, whereas the $\beta_2$microglobulin serum concentration during the second and third year correlated inversely to the decrease in CD4 T cells. An analysis of serum neopterin in 30 of these seroconverters showed similar changes. An analysis of three groups of HIV seropositive subjects with either stable high numbers of CD4 cells (>600x106/l), moderately decreasing CD4 numbers (100x106/l/year), or rapidly decreasing CD4 numbers (200x106/l/year) showed a strong inverse correlation between the rate of CD4 T cell fall and the serum concentration of neopterin and $\beta_2$microglobulin. The serum concentration of SIL-2R increased after HIV seroconversion, but in contrast to serum $\beta_2$microglobulin and neopterin, serum SIL-2R was only slightly increased in those with fast declining CD4 cells but was markedly increased in those with stable CD4 numbers.
Conclusion. Cells within the immune system, as reflected by serum $\beta_2$microglobulin, neopterin, and SIL-2R, differs in their response to HIV infection and represent different aspects of AIDS pathogenesis.

Th.B.O.27 POWER OF SERUM BETA-2-MICROGLOBULIN AND SERUM NEOPTERIN IN DETECTING ADVANCED HIV-DISEASE

Brühwiler, Johannes; Ledergerber,B.; Joller-Jemelka,H.*; Grob, PJ.* and Lüthy,R. Department of Medicine, Division of Infectious Diseases and * Division of Clinical Immunology, University Hospital, Zurich, Switzerland.

Objective: To evaluate the discriminating power of serum Beta-2-microglobulin (B2M) and serum Neopterin (NPT) between early and advanced disease.
Patients and Methods: In 497 HIV-positive patients (82% men, 18% women; 52% homo- or bisexuals, 41% drug addicts and 7% with other risks) were 54% asymptomatic (ASY), 30% had a persistent generalised lymphadenopathy (PGL), 9% ARC and 7% AIDS. The median age was 30 years (range 19-73). NPT in 1360 sera and B2M in 1366 were measured. After analysing the variances of NPT and B2M by ANOVA, the clinical stages were pooled in a group with early disease (ASY and PGL, 84%) and one with advanced disease (ARC and AIDS, 16%). For these two groups sensitivity (SENS), specificity (SPEC), predictive value positive (PVP) and negative (PVN) were calculated for different cut-off values using Bayes' formula.
Results: NPT and B2M were significantly higher in advanced than in early stages. In advanced disease the variances were very large, especially for NPT. For ascending cut-off levels (reported as factor to the upper normal limit) SENS, SPEC, PVP and PVN were rated as follows:

	cut-off	SENS	SPEC	PVP	PVN		SENS	SPEC	PVP	PVN
B2M:	1x	0.66	0.62	0.25	0.91	NPT:	0.70	0.60	0.25	0.91
	2x	0.19	0.96	0.48	0.86		0.25	0.94	0.43	0.87
	3x	0.05	0.99	0.74	0.85		0.15	0.97	0.51	0.86
	4x	0.03	1.00	1.00	0.84		0.10	0.99	0.63	0.85

Conclusions: High concentrations of B2M rather than NPT indicate advanced, low concentrations early disease. Due to a large variance, medium concentrations are not conclusive.

Th.B.O.29 HIGH INTERFERON LEVELS PREDICT SUBSEQUENT DEVELOPMENT OF AIDS

Anderson, Robert E.*; Merritt, J.**; Hamilton, R.**; Shiboski, S.***; Winkelstein, W.***.
*ViRx, Inc., San Francisco, CA, USA; **The Upjohn Company, Kalamazoo, MI, USA; ***University of California, Berkeley, CA, USA.

Objective. To determine interferon levels in prevalent HIV seropositive men and examine the relationship of interferon to the subsequent progression to AIDS.
Methods. Interferon levels were measured in a blinded fashion by an alpha-2 specific RIA and the viral plaque reduction assay on sera collected in 1985 from 86 HIV seropositive men in the San Francisco Men's Health Study.
Results. Development of AIDS by 30 months

Interferon Level	All HIV+	AIDS	(%)
Undetectable	47	15	(31.9)
0.7 - 1.0 U/ml	16	6	(37.5)
1.1 - 2.6 U/ml	10	5	(50.0)
>2.7 U/ml	13	13	(100.0)

In a Cox proportional hazards model including CD-4 and CD-8 lymphocyte counts, p24 antigen, and beta-2 microglobulin, the interferon level is a significant predictor of AIDS by 30 months (relative hazard = 2.3, p=0.04).
Conclusion. Elevated interferon levels occur in 45.3 percent of prevalent HIV seropositive men and high levels are associated with a poor disease prognosis.

Th.B.O.26 2'-5'A Synthetase and Blastogenesis as Measures of Response to Azidothymidine (AZT)

Read, Stanley, Fanning, M.,Osachoff, J.,and Coates, R. University of Toronto, Toronto, Canada

Objective: To determine whether AZT given to CDC II, III and IVc2 HIV-infected men will be reflected in changes in levels of 2'-5'A synthetase (2-5AS) and blastogenic response to mitogens.
Methods: We have previously shown, in a cohort of 22 men given escalating doses of AZT, that 600mg/d resulted in the greatest decrease in 2-5AS (n<30 pmoles) and increase in response to PHA. Further studies were done during a washout period of 13 weeks followed by 22 weeks at 1200mg.
Results: Persistent elevation of 2-5AS levels appears to be a bad prognostic sign in HIV infection. A significant drop in 2-5AS occurred on 600mg/d of AZT (85.7 to 49.8 pmoles). Also, a significant increase in response to PHA was observed. During the washout period the 2-5AS rose (45.3 to 65.5) and the PHA response dropped to below prestudy levels. 12 weeks after resuming AZT at 1200 mg, synthetase levels again dropped and PHA response increased. However, by week 84, synthetase levels had risen to 74.3. PHA response remained unchanged.
Conclusions: At 600 mg AZT, levels of 2-5AS and PHA responses normalize. Adverse changes in 2-5AS and PHA response occur with continued dose of 1200mg and when drug is discontinued.

Th.B.O.28 INTERFERON (IFN), BETA-2 MICROGLOBULIN (β_2-m) AND NEOPTERIN (Neo) IN AIDS-ASSOCIATED KAPOSI'S SARCOMA (KS).

Krown, S. Bhalla, R, Niedzwiecki, D, Bundow, D. Memorial Sloan Kettering Cancer Center, NY, NY, USA

Objective. To study the relationship between endogenous IFN, β_2-m and Neo and their value in predicting treatment response in patients (pts) with KS.
Methods. Serum levels of IFN, β_2-m and Neo were determined prior to treatment in 43 pts entered into a phase I trial of IFN-α + AZT. Pearson product moment correlation was computed to quantify the relationship between β_2-m and Neo. Two-sample t-test was used to evaluate associations between endogenous IFN activity and levels of both β_2-m and Neo. Fischer's exact test was used to evaluate associations between IFN, β_2-m and Neo and KS regression.
Results. Median pretreatment β_2-m was 3.4 (range 2.2-6.2) mg/l (normal 1.1-2.4); median Neo was 18 (range 8-64) Nmol/l (normal $\leq$10); 38% of pts had detectable serum IFN (normal, undetectable). β_2-m and Neo were significantly correlated ($r=.82$, $p=.0000$). Pts with detectable serum IFN had significantly higher β_2-m levels (4.21±.27 vs. 3.14±.11, $p=.000$) and higher Neo levels (27.8±4.3 vs. 16.1±1.1, $p=.005$) than those without detectable IFN. Although individually, β_2-m and Neo were not predictive of response, the tumors of pts with "low" levels of both (β_2-m$\leq$3.4, Neo$\leq$18) were more likely to regress (77% CR+PR) than those with higher levels of β_2-m, Neo, or both (37% CR+PR, $p=.036$). Pts with undetectable IFN showed a significantly higher response rate than those with endogenous IFN activity (71% vs. 20%, $p=.018$).
Conclusion. The response of KS to IFN-containing regimens may be predicted by measurements of IFN, β_2-m and Neo. The strong associations noted are likely due to IFN induction of β_2-m and Neo. (Supported by NIAID-ACTG).

Th.B.O.30 TUMOR NECROSIS FACTOR (TNF) IN THE PLASMA OF AFRICANS INFECTED WITH HIV.

SM Holland*, RL Colebunders‡, Francis, H.L.‡, Khondi‡, Kapita‡, Quinn·T.C** et al, *Johns Hopkins Hospital, Baltimore, Md.; ‡Projet SIDA, Kinshasa, Zaire; and**NIAID, NIH, Bethesda, Md, U.S.A.

Objective. To determine the association of plasma TNF and clinical signs and symptoms of HIV infection and AIDS in African patients.
Methods. Physical examination, demographic information, and a health questionnaire were obtained from 55 outpatients and 50 inpatients referred for HIV testing at the Mama Yemo Hospital, Kinshasa, Zaire, and 52 asymptomatic Zairian factory workers and their spouses. TNF levels (double monoclonal antibody ELISA, T Cell Sciences, Cambridge, MA), HIV ELISA, western blot, and p24 antigen level were determined for each patient.
Results. 63 (40%) of 157 cases were seropositive for HIV. Mean TNF levels were 25 ± 9.1 pg/ml for all HIV+ compared to 39 ± 12.7 pg/ml for all HIV- (NS). Among asymptomatic factory workers and their spouses, HIV+ subjects had lower TNF levels (< 10 pg/ml) than HIV- subjects (26.5 ± 10.5 pg/ml, $p< 0.05$). HIV+ patients with AIDS had significantly lower TNF levels (10.5 ± 7.5 pg/ml) than HIV- subjects (39 ± 12.7 pg/ml, $p< 0.05$). In afebrile subjects, mean TNF was lower in HIV+ (<10 pg/ml) than HIV- (29 ±13.7 pg/ml, $p< 0.05$). This same relationship was seen in patients with clinical tuberculosis (9.5 ± 5.4 pg/ml, HIV+ and 68 ± 29.6 pg/ml HIV-, $p <0.05$).
Conclusions. TNF levels in both symptomatic and asymptomatic HIV infected Zairians are depressed compared to uninfected controls. These findings are in contrast to studies of North American and European patients, in which elevated TNF levels have been associated with advanced HIV disease. These data suggest that HIV infected Zairians have impaired and depressed TNF responses.

Les problèmes associés au VIH en hémophilie : aujourd'hui et demain
HIV Related Issues in Hemophilia: Today and Tomorrow

Th.B.O.31 THE FIRST AND SECOND EPIDEMICS

Evatt, Bruce L.*. *Centers for Disease Control, Atlanta, GA, USA.

Objective. To determine the extent of AIDS in heterosexual partners of hemophilia patients.
Methods. Surveillance of heterosexual partners of hemophilia patients.
Results. By February 1989, more than 850 cases of hemophilia associated AIDS in the U.S. had been reported to the Centers for Disease Control. This represents an attack rate of about 5 to 7 per 100 of the 12,000-17,000 persons with hemophilia in the U.S. and approximately 18% of the HIV seropositive hemophilia patients. The accrural rate of AIDS in hemophilia patients has been constant for more than 3 years. Following the universal adoption of heat treated materials for therapy for hemophilia in 1984 and 1985, seroconversion of individuals receiving therapy essentially ceased. Recently an increase in transmission of HIV to heterosexual partners and to children born to women whose sexual partners are hemophilic have focused attention on this secondary epidemic. In 15 studies approximately 10% of heterosexual partners of hemophilic patients were seropositive but seroprevalence was as high as 21.4% in some studies. AIDS cases among these patients have been increasing and the epidemic curve of the heterosexual partner is similar to that of the primary epidemic that was recognized 4 years earlier in the hemophilia population. Risk reduction activities to date have had varying success at modifying behavior.
Conclusion. Risk reduction activities must be directed toward the hemophilia population and their sexual partners in order to stop this secondary epidemic.

Th.B.O.33 NATURAL HISTORY OF HIV INFECTION IN HEMOPHILIA

Tsoukas, Chris M. Division of Clinical Immunology, Montreal General Hospital, Montreal, Quebec, Canada

Th.B.O.35 HAEMOPHILIA: Special Management Issues.

Lee, Christine A.

Haemophilia and Haemostasis Unit, Royal Free Hospital, London, England.

The special management issues for haemophiliacs infected with HIV must reflect not only the underlying bleeding disorder but also the sex-linked inheritance of haemophilia. Almost all haemophiliacs infected with HIV have now been identified: education about treatment and discussion of dreaded isses can be started before the onset of symptoms. As a result the recruitment to, and compliance within, trials of treatment for asymptomatic haemophiliacs may be better than in other patient groups. The presence of an underlying bleeding disorder makes the investigative procedures required to diagnose many clinical problems more difficult. Operative procedures - for example, joint replacement - may encourage HIV-related complications. The double coagulopathy of clotting factor deficiency and HIV-related thrombocytopenia raises additional clinical problems. Many haemophiliacs have multiple chronic virus infections - hepatitis B, C and D - which may respond to interferon. As haemophiliacs must continue to receive clotting factor concentrates, vaccination against B virus is mandatory, but the antibody response is not predictable. Adolescents have to declare both haemophilia and HIV early in their relationships; counselling this group is a delicate management issue. Couples may want to have children and the facts should be presented sympathetically for informed decisions to be made. Haemophilia, by the nature of its sex-linked inheritance, is a disorder of the whole family; the management of the individual patient inevitably involves other family members. Finally, litigation is an emergent special management issue which threatens the relationship between the haemophiliac and his health care provider.

Th.B.O.32 VIRUCIDAL METHODS FOR CLOTTING FACTOR CONCENTRATES: ARE THEY EFFECTIVE?

P.M. Mannucci

A. Bianchi Bonomi Hemophilia and Thrombosis Center and Institute of Internal Medicine, University of Milano, Italy

Although the widespread infection of hemophiliacs with the human immunodeficiency virus contaminating clotting factor concentrates is still a threatening and formidable shadow, the gloomy picture brought about by the AIDS epidemic is partially lightened by recent spectacular improvements in the safety of concentrates. An important step-forward towards the elimination of the risk of infections transmitted by large-pool concentrates is the development of virucidal methods that inactivate those blood-borne agents that have escaped the filter of donor screening. Since the human immunodeficiency virus appears very vulnerable to such methods, currently available concentrates can be considered substantially free from the risk of transmitting that virus. Even though transmission of hepatitis viruses is much reduced but not totally abolished, virucidal methods are continuously being improved, so that it can be foreseen that concentrates will became safer and safer.

Th.B.O.34 RATES, MARKERS AND COFACTORS OF HIV INFECTION AND AIDS IN HEMOPHILIACS

James J Goedert, Viral Epidemiology Section, National Cancer Institute, Bethesda MD 20892 USA.

Objective. To quantify the incidence of HIV (1977-89) and AIDS [after HIV seroconversion(+)] and to evaluate the effect of age on two phases: HIV+ to occurrence of an AIDS marker, then from marker to an AIDS diagnosis.
Methods. Annual hazard rates of HIV for a prospective multicenter cohort of 1219 subjects with hemophilia were modeled as piecewise constant with GAUSS. For 319 subjects with HIV mid-point seroconversion dates we compared 1) the incidence of drop in CD4 count, rise in interferon and p24 antigen (Abbott), and loss of p24 and gp120 antibodies (RIA) and 2) AIDS incidence overall and after each marker with actuarial methods and log-rank tests of significance.
Results. AIDS incidence following seroconversion was 2.00/100 person-years and was directly related to age (from 0.62 for ages 1-11 to 4.24 for ages 35-70, $p=0.00003$). Type/severity of hemophilia, race, and factor concentrate dose had little effect ($p=0.50$). Annual incidence ranged from zero during the first year following seroconversion to 7% during the eighth year, with cumulative rates of 13.3% (±5.3% SE) for ages 1-17, 26.8% (±6.4%) for ages 18-34, and 43.7% (±8.5%) for ages 35-70. CD4 loss was high in older adults ($p\leq0.005$); anti-p24 loss was low in adolescents ($p=0.005$); and AIDS after loss of anti-p24 was low in children aged 1-17 ($p=0.03$).
Conclusion. Because several laboratory markers appear and predict AIDS risk at various rates as a function of age: 1) there are likely to be more HIV-infected children and adolescents than currently estimated; 2) prediction of AIDS in youngsters with available markers will be more difficult; and 3) drug efficacy trials will need 3-fold more children than adults.

Th.B.O.36 CONCENTRATES: MEETING THE DEMAND

Aledort,Louis M., Prof. of Medicine, Dean for Faculty & Medical Affairs
The Mount Sinai Medical Center, New York, New York, U.S.A.

The adequacy of a nation's blood supply can be measured by whether or not it can meet the needs of its hemophiliacs. Prior to HIV infection, bleeding was the leading cause of death; transfusion transmitted hepatitis sequelae was second. For the hemophiliac, survival and quality of life depend not only on safety and efficacy of product but on availability. The United States, because of technology and liberal plasmapheresis regulations, is able to meet its own needs and to export 50 percent of the factor produced as well as a third of its pheresed plasma. This is the result of a highly developed industry that has the capability for large scale production. Self-sufficiency as a country's policy is a laudable goal; however, we must ensure an adequate supply of product for those whose lives depend upon it. The European Community ("EC") is currently considering a directive that would ban importation of blood products derived from paid donors. In fact, most of the EC nations do not have adequate plasma supplies nor fractionation programs to meet their current needs. Indeed, these are the very countries importing 80% of the materials exported by the U.S. Sixty percent of all the product used in these nations is derived from paid donor plasma. In addition, few countries throughout the rest of the world can meet their current or future needs. Premature implementation of the EC directive could cause a devastating shortage for hemophiliacs. Because of limited resources, self-sufficiency may never be achieved. International interdependence has many advantages; economy of scale, rapid transfer of advanced technology, and potential cost savings for countries currently without fractionation programs. However, we need to go beyond the global issues to those of the individual patient. Many hemophiliacs are now HIV positive; they deserve an uninterrupted supply of affordable products.

SIDA et nutrition
Nutrition and AIDS

Th.B.0.37 EFFECT OF HOME TOTAL PARENTERAL NUTRITION UPON BODY CELL MASS IN AIDS.

Kotler, Donald P; Tierney, AR; Culpepper-Morgan, JA; Wang, J; Pierson, RN.
St.Luke's-Roosevelt Hospital, Columbia University, New York, NY, USA

Objectives. To determine if parenteral nutritional therapy can successfully replete body cell mass in malnourished AIDS patients; to determine clinical features associated with successful body cell mass repletion.
Methods. A longitudinal study of body composition was performed in 12 AIDS patients receiving total parenteral nutrition at home (TPN). Measurements included body weight, total body potassium (TBK), a measure of body cell mass, which was determined in a whole body counter, and body fat content, which was determined anthropometrically.
Results. Two patterns of response were seen. Six patients gained weight and increased TBK and body fat content. The clinical responders included patients with eating disorders or severe small intestinal injury with nutrient malabsorption. The other 6 patients gained weight and fat, but not did not increase TBK. The nonresponding patients all had serious systemic infections with cytomegalovirus and/or mycobacterioses, among others. Clinical improvement mirrored changes in TBK but not body weight or fat.
Conclusions. Parenteral nutritional therapy in AIDS may result in body mass repletion. Favorable responses occur in patients who have problems with nutrient intake or absorption. Unfavorable responses occur in patients with serious systemic infections.

Th.B.0.38 INCREASED RESTING ENERGY EXPENDITURE IN HIV-INFECTED MEN.

Hommes, Mirjam*; Romijn, J.A.*; Godfried, M.H.*; Endert, E.**; Danner, S.A.*; Sauerwein, H.P.**.
Depts. of *Internal Medicine and **Endocrinology, Academic Medical Centre, Amsterdam, The Netherlands.

Objective. To investigate wether unexplained weight loss in clinically stable HIV-infected patients may be caused by increased rates of resting energy expenditure (REE).
Methods. REE was determined in the postabsorptive state by indirect calorimetry in 14 slowly weight-loosing HIV-seropositive men (6 AIDS patients, 8 patients with ARC, age: 28-56 yrs.). All patients were free of acute infectious illness and without evidence of malabsorption. A group of 11 healthy male volunteers (age: 25-51 yrs.) served as a control group. Body composition was measured with a body impedance analyser.

Results. (mean ± SD)		patients	controls	p-value*
fat free mass	%	80 ± 5	80 ± 6	ns
REE	kCal/kg.day	27 ± 3	23 ± 2	<0.01
energy intake	kCal/kg.day	33 ± 12	31 ± 9	ns

*Wilcoxon's rank sum test for unpaired data.
Catecholamines, cortisol, glucagon and triiodothyronine were not statistically different between patients and controls.
Conclusion. Even in the absence of acute illness patients with AIDS or ARC have increased rates of REE, which might be responsible for the unexplained wasting sometimes observed in these patients. This hypermetabolism is not explained by higher levels of catecholamines or triiodothyronine.

Th.B.0.39 HUMAN IMMUNODEFICINCY VIRUS INFECTION IN MALNOURISHED CHILDREN AT KENYATTA NATIONAL HOSPITAL, NAIROBI, KENYA

Luta, Martin, Anabwani, G and Braddick, M.
Department of Paediatrics, University of Nairobi, Kenya.

Objective: To determine whether there is an association between protein-energy malnutrition and HIV infection in children.
Methods: In 1987 one hundred children, 6 to 24 months of age (mean 14 months), admitted to Kenyatta National Hospital, with protein-energy malnutrition, were screened for HIV infection by Elisa test. Positive results were confirmed by Western Blot. These were compared with results obtained from 100 normal children (mean age 8 months) (controls).
Results: Six per cent of the malnourished children and 1% of the normal children were seropositive (P<0.05). Seropositivity was associated with the presence of more than one clinical problem on admission: chronic cough and chest X-ray with evidence of infection. Mortality was 66% in the seropositive and 15% in the seronegative malnourished children (P<0.01). In addition, the WHO criteria for diagnosis of paediatric AIDS was not useful in this study as only 1 of 7 seropositive children satisfied these criteria. However, a significant number of seronegative malnourished children satisfied all these criteria. Seropositivity was not associated with previous transfusion.
Conclusions: Our findings suggest that, at the time of study, HIV seropositivity was significantly higher in malnourished children.

Th.B.0.40 NUTRITIONAL ABNORMALITIES IN EARLY HIV-1 INFECTION
I. PLASMA VITAMIN LEVELS

Beach, Richard S.*,**; Mantero-Atienza, E.*,**; Van Riel, F.*,**; Morgan, R.*,**; Fordyce-Baum, M. K.*,**. *Department of Epidemiology and Public Health and **The Biopsychosocial Center on AIDS, University of Miami, School of Medicine, Miami, Florida, USA

Objective. To determine the nutritional status of participants by measuring plasma vitamin levels by standard methodology.
Methods. We have evaluated 50 HIV-1 seropositive homosexual males (western blot) who were asymptomatic other than lymphadenopathy (CDC stage III).
Results. No clinical signs and symptoms of malnutrition were found in the study subjects upon examination. However, while thiamin and riboflavin status as measured by activity coefficient assays,did not show deficiency, pyridoxine levels were found inadequate in 35% of subjects as compared with controls (p<0.01). In addition, levels of vitamin B_{12} were significantly lower than those of controls from a similar age group (p<0.01); 35% of the subjects had vitamin B_{12} levels considered to represent overt deficiency (<200pg/ml) as well as a further 12% could be described at high risk for cobalamin deficiency (200-400 pg/ml). In contrast, plasma and erythrocyte folate levels were significantly elevated in 67% and 72% of the subjects respectively. No ascorbic acid deficiency was found at the time of investigation; plasma vitamin A and tocopherol levels were found to fall within a range considered normal in young adult males.
Conclusion. HIV-1 infection even in the earlier relatively asymptomatic stages is associated with significant metabolic/biochemical abnormalities. These alterations may play a role in the development of HIV-related immune dysregulation as well as opportunistic infection, malignancies and encephalopathy.

Th.B.0.41 ILEAL ABSORPTIVE FUNCTION IN ACQUIRED IMMUNODEFICIENCY SYNDROME (AIDS)

Kapembwa Moses, Bridges, C.; Joseph, A.E.A.; Fleming, S.C.; Griffin, G.E.
St. George's Hospital Medical School, Cranmer Terrace, London, SW17 0RE.

Objective. To investigate terminal ileal absorptive function in AIDS.
Background. Enteropathy affecting the jejunum has been described in AIDS but there is no such information concerning the ileum. We have concurrently assessed ileal function and fat absorption in a group of AIDS patients.
Methods. Terminal ileal absorptive function was investigated in 7 subjects using a previously validated test in which the loss of a radio-labelled synthetic bile acid ^{75}Seleno-23-homocholic acid-Taurine (^{75}SeHCAT) from the enterohepatic circulation is quantitated by abdominal γ-scanning. In addition ^{57}CoVitamin B12 (Vit B12) absorption was measured. Concurrently fat absorption was assessed using the ^{14}C Triolein breath test (CT) and indirect tests of small intestinal bacterial overgrowth, ^{14}C Glycocholate (GC) and breath Hydrogen (BH) were carried out. Stool microscopy for enteropathogens was performed in each subject.
Results. Normal bile acid and Vit B12 absorption were demonstrated in 5/7 patients (mean SeHCAT loss 20%/day; normal<30%/day: mean plasma Vit B12 at 10 hours 1.74%/L; normal>0.5%/L). All 5 subjects had reduced fat absorption (mean CT 87x10^{-4}%; normal>140x10^{-4}%). Enteropathogens and small intestinal bacterial overgrowth were not detected in any of these subjects.

2/7 subjects had reduced absorption of bile acid (SeHCAT loss 90%/day; 59%/day), Vit B12 (0.25%/L; 0.16%/L) and fat (CT 4x10^{-4}%; 133x10^{-4}%). Both patients had an enteropathogen (cryptosporidium and isospora) on stool and jejunal histological examination. None of the two subjects had evidence of small intestinal bacterial overgrowth.
Conclusion. AIDS patients may have normal ileal absorptive function in the presence of jejunal disease. Infection with cryptosporidia or isospora may however be associated with ileal dysfunction.

Th.B.0.42 IMBALANCE OF THE AMINO ACIDS PATTERN IN PATIENTS WITH AIDS - SPECIAL TREATMENT WITH ADAPTED AMINO ACID SOLUTION?

P.-H. Althoff, E. Schifferdecker, H. Förster, B. Michels, P. Hanold, St. Klenke, A. Falkenbach, E. Holz, K. Schöffling, University Hospital, Frankfurt, FRG.

More than 60 % of the patients with AIDS were underweight on admission and there are signs of diarrhea, malabsorption and development of malnutrition. Malnutrition and deficiencies of protein as well as of specific nutrients is a well-established cause of immunodeficiency.
In view of the importance of amino acids for metabolism and endocrinology (synthesis of neuro-transmitters and hormones) we report on measurements (intermediate pressure liquid chromatography; nmol/0,1 ml) of patterns of 21 amino acids (AA) in fasting plasma of 23 patients with AIDS (CDC IV; WR6; Frankfurt 3): Group A (n=10): body mass index (BMI < 19; group B (n=13): BMI >19, compared with AA patterns gained in group C (n=8): patients with ARC (AIDS-related complex) and group D: a large control group (n=121).
Compared with controls (gr D) and ARC (gr C) nearly all AA were significantly decreased in AIDS-patients of group B ((BMI>19) and more pronounced in AIDS-patients of group A (BMI<19). Especially: serine - 38,3% (gr D: 164,5±31,6; gr B: 123,0±30,6; gr A: 101,5±24,7). Glutamine -30%; alanine -43 %; valine -26,3%; methionine -48,6%; isoleucine -41,5%; leucine -33,7%; tyrosine -22,2%; histidine -45,7%; threonine -48,4% and tryptophan -50,2%.
Our data shows a rather uniform decrease of most AA, especially of branched chain and aromatic AA and, using another category, of essential AA. These findings do not simply resemble the pattern seen in starvation, anorexia nervosa or critical ill patients. The low tyrosine and tryptophan levels (neurotransmitter precursors) are inter-esting in view of behaviour (depression; lethargy, etc.), but also protein-(albumine)-synthesis (tryptophan). Special treatment with adapted amino acid solutions could be of benefit.

Immunomodulateurs
Immunomodulators

Th.B.O.43 A PLACEBO-CONTROLLED TRIAL OF INTERFERON ALFA-2B IN ASYMPTOMATIC HIV INFECTION

Davey, Victoria; Kovacs, JA.; Herpin, B.; Metcalf, JA., Fauci, AS., Lane, HC.; et al.
National Institutes of Health, Bethesda, Maryland, USA.

Objective. To assess in asymptomatic men who were seropositive and culture positive for HIV the *in vivo* efficacy of interferon alfa-2b (IFN), as defined by changes in HIV isolation, CD4 counts, and development of an AIDS-defining opportunistic infection. Methods. Thirty-four asymptomatic HIV ELISA and Western Blot positive homosexual men with positive peripheral blood lymphocyte (PBL) cultures for HIV and CD4 counts of ≥ 400/mm³ were randomized to receive either 35 million units of daily subcutaneous IFN or placebo. Doses of IFN or placebo were modified according to pre-defined laboratory changes and subjective complaints. Duration of therapy was a minimum of 12 weeks. Results. Seventeen patients were randomized to receive IFN, and 17 to receive placebo. Age, past history of sexually transmitted diseases, and mean T4 counts were comparable between the two groups at entry. Sixteen of seventeen patients completed at least 12 weeks on placebo; 11/17 completed at least 12 weeks on drug. The average daily dose of drug for patients in the IFN group was 17.5 million units. All patients on IFN reported flu-like symptoms; other toxicities noted were granulocytopenia (55%), liver function test abnormalities (45%), and anemia (18%). Seven of eleven IFN patients (64%) became HIV culture negative (defined as 3 or more consecutive negative PBL cultures taken at least 2 weeks apart) while on drug; 2/16 (13%) placebo patients developed negative HIV cultures while on study (Fisher's p=.008). The average time to development of negative cultures was 11 weeks. One p24 antigenemic patient was randomized to IFN; his p24 antigen levels declined from > 20,000 pg/ml to < 200 pg/ml over 47 weeks. In follow-up of study patients ranging from 3 to 24 months, 0/11 IFN patients vs. 3/16 placebo patients have developed an AIDS-defining opportunistic infection (OI) (Fisher's p=.19). Absolute CD4 lymphocyte counts in placebo patients have declined from baseline by an average of 24% vs 4% for the IFN group (p=.11). Conclusion. Interferon alfa 2b has significant activity in patients with HIV infection as evidenced by a decrease in viral shedding, and its use may decrease the rate of development of first OI, and reduce the rate of CD4 decline. Thus, administration of IFN, while accompanied by dose-dependent toxicities, may have a role in slowing progression of HIV disease.

Th.B.O.45 INTRAMUSCULAR POLY-ICLC ADMINISTRATION IN AIDS: PRELIMINARY FINDINGS

SALAZAR, ANDRES M.*; MORALES, J.**; LEVY, H.B.†; SARIN, P.‡; TORO, L.*; HAWKES, C.*; & WALTER REED RETROVIRUS RESEARCH GROUP.
*Uniformed Services University of the Health Sciences, Bethesda, Maryland, & Walter Reed Army Medical Center, Washington, DC; **Ashford Presbyterian Hospital, San Juan, Puerto Rico; †NIAID & ‡NCI, NIH, Bethesda, Maryland, USA.

The synthetic double stranded RNA Poly-ICLC (PICLC) induces high levels of interferons α and β in man, along with increased Interleukin I and II, Colony Stimulating factor (CSF), and corticosteroids. Other effects include NK cell, macro-phage/monocyte, and B-cell activation, specific cytotoxic T-cell development, increased T_4/T_8 ratio, and expression of histocompatibility antigens. In some malignancies, there is also an antineoplastic effect.
Objective. To determine the safety and toxicity of intramuscular PICLC in AIDS patients.
Methods. Two to six mg PICLC was administered intramuscularly (IM) weekly with or without Zidovudine over a six to 12 month period to nine HIV infected patients with T_4 counts between 0 and 200.
Results. Low dose IM PICLC was well tolerated, with no significant clinical or laboratory toxicity. Side effects, as expected, consisted of a flu-like syndrome with low grade fever and malaise lasting 12-24 hours. Most patients report an initial weight gain and improvement in fatigue and other constitutional symptoms; there have been no deaths. T_4 counts have remained stable or risen in 8/9 patients. At present HIV cultures are negative in 8/9 patients. Preliminary clinical and laboratory results relevant to safety and toxicity at 10-18 months of administration will be presented.
Conclusions. IM PICLC can be safely administered to HIV infected patients, and randomized Phase II trials are indicated to explore potential efficacy.

Th.B.O.47 FOLLOW-UP MORBIDITY AMONG ARC PATIENTS ON POST-TRIAL IMREG®-1 TREATMENT

Gottlieb, Marise S*, Zackin, R*; IMREG®-1 Trial Investigators** and Gottlieb, A* *Imreg, Inc. and IMREG®-1 Trial Sites at **Boston, MA, **Cleveland, OH, *,**New Orleans, LA, **New York, NY, **Philadelphia, PA and **Rancho Mirage, CA. U.S.A.

Objective. To determine longer term benefits from IMREG®-1, an immunosupportive therapy in ARC patients. Methods. After 6 months of receiving either IMREG®-1 or placebo or experiencing an AIDS-defining or AIDS-related event while enrolled in a double-blind randomised clinical trial, patients could receive treatment with IMREG®-1 on a continuation protocol. There were 27 patients who had been assigned to placebo and 60 patients assigned to IMREG®-1 who elected to receive IMREG®-1. Patients differed in the number of post-Trial weeks of treatment they received. The probability of experiencing an AIDS-defining or AIDS-related event is considered for the number of weeks subjects continued in their Trial assignment. Results. During the trial 93 patients received IMREG®-1, 4 of whom developed an AIDS-defining or AIDS-related event in 2117 patient-weeks; among the 48 patients assigned to placebo and followed for 1021 patient-weeks, 12 developed an AIDS-defining or AIDS-related event. Kaplan-Meier (K-M) probability was 0.05 for the treated and 0.28 in the untreated groups (p=0.0004). Beyond the trial, patients maintaining trial treatment assignment had a K-M probability of an AIDS-defining or AIDS-related event of 0.15 in 3942 patient-weeks for IMREG®-1 treatment and 0.40 in 1503 patient-weeks for the placebo group (p=0.0004). Conclusion. Reduction in disease progression associated with IMREG®-1 treatment is observed for several months beyond the Trial.

Th.B.O.44 IMMUNIZATION WITH INACTIVATED, ENVELOPE-DEPLETED HIV IMMUNOGEN IN HIV INFECTED MEN WITH ARC: PRELIMINARY REPORT OF EXPLORATORY STUDIES IN PROGRESS.

Levine, Alexandra;[1] Henderson, BE;[1] Groshen,S;[2] Peters,R;[2] Shepard, HW;[3] Salk, J;[4] et al. Univ Southern Cal School Med, Los Angeles,[1] CA; Immune Response Corp,[2] La Jolla, CA; Dept Health Services, Berkeley, CA;[3] Salk Institute,[4] La Jolla, CA, USA.

Objective: To study the feasibility of active immunization, with irradiated, envelope-depleted HIV immunogen, administered to HIV seropositive, viremic subjects in an attempt to prolong their asymptomatic state, or to prevent the progression to AIDS.
Methods: 20 ugm of HIV immunogen, emulsified in Freund's incomplete adjuvant, or in saline, was given IM or ID to 19 pts with biopsy-proven PGL. Median follow-up with PGL, prior to study entry was 31-45 mos. Serial measures of clinical status, p24 Ab and Ag, CD4, CD8 cells, skin tests, & HIV viral culture were performed monthly.
Results: Median follow-up is 48 wks (28-52) since inoculation. No significant toxicity has occurred. One subject, with initial p24 antigenemia developed AIDS at 5 mos. All others remain clinically well, without AIDS. CD4 cells, at last f/u reveal an increase over baseline values in 11/19 (58%), while 13/18 (p=.05) had an increase over the value projected from pre-inoculation trends. At entry, six were anergic and 22 skin tests were positive: at f/u, no pt is anergic, and 59 tests are positive. DCH confirmed by biopsy.
Conclusion: (1) The HIV immunogen is safe in these subjects (2) A controlled, randomised trial is in progress: results will be presented.

Th.B.O.46 ISOPRINOSINE REDUCED CLINICAL PROGRESSION IN HIV INFECTED PATIENTS IN A DOUBLE BLIND PLACEBO CONTROLLED STUDY.

The Scandinavian Isoprinosine Study Group, Hidovre, Denmark.

Objective. To determine the influence of isoprinosine (Imunovir) on the clinical course of HIV infection.
Methods. A total of 866 HIV infected patients from Sweden and Denmark were randomised and stratified according to CD_4-count to receive either isoprinosine 1 g t.i.d. (n=429) or matching placebo (n=437) for 6 months. At baseline the study population consisted of 765 asymptomatic patients and 101 symptomatic patients. Patients with AIDS were not included.
Results. Eighthundred and thirty-three patients were eligible for efficacy analysis. There were no significant differences between the two groups with respect to CD_4-count or clinical status at baseline.
Progression to AIDS according to CDC revised definition:

	AIDS (%)	no AIDS
Placebo	* 17 (4)	404
Isoprinosine	** 2 (0.5)	410

* 10 PCP, 3 KS, 1 oesophageal candidiasis, 1 encephalopathy, 1 HSV > 4 weeks, 1 wasting
** 2 PCP

$p < 0.001$ Odds ratio = 8.6, 95% confidence limits: 1.9 - 54.5

During treatment no significant differences in CD_4-count occurred. No serious side effects were observed. Minor adverse reactions occurred with equal frequencies in both groups.
Conclusion. Isoprinosine offers a potential treatment modality, particularly in the asymptomatic HIV infected patients. However, the mode of action remains to be clarified.

Th.B.O.48 THE ANTI-HIV DRUGS CASTANOSPERMINE (CSP) AND DEXTRAN SULFATE (DS) ALSO ALLOW THE GROWTH OF IN VIVO INFECTED CD4+ T CELLS

Izaguirre, Carlos A. and Drouin, J. Department of Medicine, University of Ottawa and Ottawa General Hospital, Ottawa, Ontario, Canada.

We have reported that CSP and DS rapidly induce the regeneration of CD4+ T cells and T cell colony precursors in cultures from blood lymphocytes of HIV+ patients. Objective.- To describe the effect of both drugs on in vivo infected CD4+ T cells. Methods.- a) T cell colony assay, b) Lectin/IL2 stimulated lymphocyte cultures, c) Coculture assay for detection of HIV, d) Reverse transcriptase assay, and e) Immunofluorescence assay using a standard polyclonal human IgG anti-HIV and monoclonal antibodies. All cultures were done in the presence and absence of 25 µg/ml of CSP or DS. Results.- We found that CSP and DS induced the regeneration of T cell colonies from very low to normal levels: when the colonies were collected, pooled and stained with anti-HIV antibodies, from 3 to 40 % of the cells were HIV positive (10 experiments). In coculture experiments we found that CSP did not prevent or delay the production and release of virions as quantitated by high levels of reverse transcriptase in the supernatants (4 experiments). Conclusions.- The beneficial effect of CSP and DS on CD4+ T cells is counteracted by the observation that both drugs also permit the growth of in vivo HIV-infected CD4+ T cells. The expansion of the population of HIV-infected cells may cause un undesirable increase in the viral load in the host. Thus, both drugs may have to be used in combination with drugs that prevent virus replication.

Pharmacologie des médicaments anti-SIDA
Pharmacology of Anti-AIDS Drugs

Th.B.O.49

PHARMACOLOGICAL PRINCIPLES APPLIED TO ANTIVIRAL TREATMENT IN AIDS

Ruedy, John.
St. Paul's Hospital and University of British Columbia, Vancouver, Canada.

Pharmacological principles are based on an understanding of the molecular mechanism of action of a drug and of its dose-response characteristics and pharmacokinetics. Efficient antiviral drugs must be selectively toxic, preferentially affecting mechanisms shared by the virus and host cell or modifying processes unique to the virus. Several fundamental aspects of cancer chemotherapy may be applicable to antiviral treatment of AIDS including exploitation of a knowledge of cell-cycle kinetics (nucleoside analogues such as zidovudine have no effect on the latent virus), and of the fact that virus (cell) kill is a first order process (achieving total kill may involve combination or sequential treatment). Resistance can be expected and has been seen with other antiviral therapies. Effective dose regimens should be based upon the establishment of the minimum effective and maximum tolerated doses, the duration of effect and the pharmacokinetics of the drug. Some agents (e.g., zidovudine, ribavirin) are pro-drugs dependent upon intercellular activation. This necessitates a knowledge of intracellular kinetics for optimal therapy.

Th.B.O.50

PHARMACOKINETICS OF ZIDOVUDINE (ZDV) IN ADULTS AND CHILDREN

Berry, David W., and Blum, M.R.
Burroughs Wellcome Company, Research Triangle Park
North Carolina, USA

The pharmacokinetics of ZDV has been evaluated in HIV-infected adults during intravenous (IV) and oral (PO) dosing. Dose-independent kinetics was observed over the ranges of 1 to 5 mg/kg and 2 to 10 mg/kg following IV and PO dosing, respectively. The major route of elimination is by formation of the inactive 5'-O-glucuronide. Mean half-lifes for drug and metabolite were about 1 hour. ZDV total body clearance (CL) and renal clearance were 27 ml/min/kg and 5 mg/min/kg, respectively. ZDV penetrated the blood brain barrier as indicated by a CSF/plasma ratio averaging 0.5 determined 2 to 4 hours following dosing. Although almost completely absorbed, the average oral bioavailability of ZDV was 65% because of first-pass metabolism. Oral doses of 200 mg every 4 hours produce mean peak and trough levels of 1.2 and 0.1 mcg/ml, respectively. Drug interaction studies have shown that concomitant administration of acyclovir has no effect on ZDV kinetics, while probenecid decreases CL by 50%. In general, the pharmacokinetics and bioavailability in children is very similar to adults. Preliminary data in neonates shows a reduced CL in newborns which approaches adult values by 1 month of age. Mean bioavailability in the neonates is 69%. Additional studies will address the relationship between pharmacokinetic parameters, viral replication times, and clinical efficacy.

HIV-2 and Other Retroviruses

Th.B.O.54 DETECTION OF HIV2 ANTIBODIES WITH A NOVEL HIV2 TRANSMEMBRANE SYNTHETIC PEPTIDE IN A LINE-IMMUNOASSAY

Peeters, Martine*; Pollet, D.**; Honoré, C.*; Brun-Vézinet, F.*** Delaporte, E.*; Van Heuverswijn H.**.
* Centre International de Recherches Médicales, BP 769, Franceville, Gabon;
** INNOGENETICS, Autwerp, Belgium;
*** Hôpital Claude Bernard, Paris, France.

Objectives. The evaluation of a novel line-immunoassay (LIA) with recombinant HIV1 and HIV2 proteins for screening of known HIV2 antibody positive sera.
Methods. The LIA-HIV assay (INNOGENETICS N.V.) uses only high purified synthetic HIV proteins in a line-immunoassay technique for the detection of antibodies to HIV. This assay uses four purified synthetic HIV-1 antigens : the major core protein p24, an additional core protein p17, a polypeptide from the gp41 region of the envelope gene and p31, a polypeptide derived from the endocuclease region of the polymerase gene. In order to detect HIV2 infected individuals a synthetic transmembrane glycoprotein of this virus has been applied. A total of 55 known HIV2 antibody positive sera (presence of gp36 and/or gp205-140) were screened.
Results. All the 55 HIV2 antibody positive sera reacted with the HIV2 transmembrane protein in the LIA test. 61% of the sera reacted with the p24 and 33 protein, 15% reacted with the p24 only, 14% with p34 only, 4% with p17 and p24, and 2% with p17, 24, 34 and 7% of the sera did not react with any HIV1 peptide. Of the 55 HIV2 sera, none of them was reactive with the gp41 synthetic peptide. There was a good correlation between the results obtained with the LIA and the western blot patterns.
Conclusion. We have shown that the LIA system using synthetic HIV1 and HIV2 peptides allows the determination of HIV2 antibody positive sera.

Th.B.O.55 COMPARAISON DES PERFORMANCES D'UN REACTIF ELISA UTILISANT UN PEPTIDE RECOMBINANT POUR LA DETECTION DES INFECTIONS A HIV 2.

(F. CATALAN*, A. MILOVANOVIC*, T.D.LY*, K. GOEHOURI**, J. MOREAU**, A. KADIO**)
* Institut Alfred Fournier - Paris - France.
** Service des Maladies Infectieuses - CHU de Treichville - Abidjan - Côte d'Ivoire.

Objectifs : Un nouveau test ELISA utilisant un peptide recombinant de HIV 2 (*Clonatec France*) fixé sur un support solide (plaque de polystyrène), a été appliqué à la détection des anticorps dirigés contre le virus de l'immunodéficience humaine (HIV 2) en milieu africain.

Méthodes : Une population Africaine de 541 sérums a été testée et la sensibilité a été comparée aux tests ELISA classiques (*Organon, Dupont de Nemours* pour HIV 1 et/ou *ELAVIA 2*) et à un test ELISA HIV 1 recombinant (*Immunocomb PBS Organics*) et s'est révélée de sensibilité identique pour les tests de dépistage (97,7 %). La spécificité est également très acceptable, comparée aux mêmes tests (98,5 %).

Résultats : Au cours de l'examen de dépistage, 5,54 % des sérums testés ont été trouvés faussement positifs par les techniques ELISA classiques, alors que seulement 2,9 % l'a été dans une première détermination pour *Clonatec*, mais les contrôles n'ont pas confirmé cette positivité. 22 sérums sur 30 ont paraissé positifs en ELISA (faux positifs) alors que cette positivité n'a pas été confirmée.

Par ailleurs, tous les sérums positifs ont été confirmés en Western blot HIV1 (24,6 %), HIV 1 + 2 (17,7 %) ou HIV 2 (11,3 %).

Conclusion : Dès lors, le test dont la facilité d'emploi est extrême (30 minutes), peut tout à fait être appliqué dans la sérologie de dépistage et peut être d'une grande utilité, en milieu africain, car il se réalise dans un minimum de temps.

Th.B.O.56 A NOVEL ENZYME IMMUNOASSAY TO DETECT ANTIBODIES TO BOTH HIV-1 AND HIV-2.

Beckford, Urssula; Roberts, C. Duncan, R.J.S. and Faye, S.
Wellcome Diagnostics Research, Beckenham, Kent, BR3 3BS, U.K.

Objective. To develop an enzyme immunoassay capable of detecting antibodies to the known types of HIV with a sensitivity greater than commercially available at present.
Methods. Recombinant and peptide immunodominant epitopes constructed from HIV-1 and HIV-2 were labelled with alkaline phosphatase and used in an antigen-sandwich enzyme immunoassay. After the capture reaction, the enzyme was measured with an amplifying one-step substrate cycle.
Results. The assay had a sensitivity by end-point dilution up to 10-fold better than the anti-HIV-1 assays currently available in Europe, and had an excellent reactivity with sero-conversion samples. It detected all of the 289 anti-HIV-1 samples obtained world-wide, all of the 189 anti-HIV-2 samples obtained from West Africa and Europe, and had a low rate of false positivity. The assay was usable with serum, plasma or heat inactivated serum samples.
Conclusion. It is possible to improve on the sensitivity of the currently available commercial anti-HIV-1 assays and to detect anti-HIV-2 with an assay designed to be compatible with current blood bank procedures.

Th.B.O.57 COMPARISON OF SEROLOGIC ASSAYS FOR TRANSFORMING RETROVIRUSES

Roberts, Chester; Romines, C.; Damato, J.; Burke, D.S.;
Walter Reed Retrovirus Research Group, Walter Reed Army Inst. of Res. Washington, D.C.

Objectives. To compare different methodologies for the serologic diagnosis of human transforming retrovirus infection.
Methods. Sera were obtained from civilian applicants for the armed services of the United States and initially screened with a qualitative HTLV-1 enzyme-linked immunosorbent assay (ELISA). Reactive samples were then tested with a recombinant envelope based ELISA and by a Western blot method.
Results. Of 3,995 samples screened by the ELISA, 66 (1.65%) were scored as either repeat reactive (34=.85%) or as questionable reactives (32=.8%). Western blot analysis revealed that 3 (4.5%) showed banding patterns suggestive of HTLV-1 infection. No bands were apparent on 35(53%) of the original 66 samples. These samples were also analyzed by a recombinant envelope based ELISA resulting in 18 (27.3%) scored as positive including the 3 that were Western blot positive. Of the other sera scored as positive by the recombinant ELISA, 7 were negative by Western blot while 6 showed p19 bands, 1 showed p19 and p28 bands and 1 showed p19, p28, and p32 bands. 48 sera samples scored as negative by the recombinant ELISA were also scored as negative by Western blot. Of the original 3,995 samples tested, 3 (.075%) can be considered positive for a transforming retrovirus by two different ELISA methods and by a Western blot method.
Conclusions. A recombinant envelope based ELISA can be used as a second level test prior to Western blot analysis to reduce screening false positives.

Th.B.O.58 SEROLOGIC EVIDENCE OF RETROVIRAL INFECTION IN INTRAVENOUS DRUG ABUSERS (IVDAs)

Nichols, David*; Wiebel, W.**; Stevko, B.** and Landay, A.*. *Rush Medical Center, Chicago, Il. and **AIDS Project, University of Illinois at Chicago, School of Public Health, U.S.A.

Objective. To evaluate serologic evidence of HIV-1 and HTLV-I co-infection in IDVAs.
Methods. Sera collected in 1988 from 1200 asymptomatic IVDAs were screened for HIV antibody(HIV-Ab) by enzyme immunoassay (EIA) (Abbott) and confirmed by Western Blot (DuPont). A subgroup of 94 IVDAs were screened by EIA (Abbott) for HIV-1 antigen (HIV-Ag) and HTLV-I Ab. Initial HTLV-I reactives were repeated in duplicate. Reactive HIV-Ag samples were neutralized.
Results. The overall seroprevalence among the 1200 IVDAs was 17% (per DuPont criteria). A subgroup of individuals was stratified by HIV-Ab status. The HIV-Ag seroprevalence was similar between the HIV-Pos (2/40) and HIV-Neg (1/40) individuals. The HTLV-I Ab positive rate among the 80 individuals was 35% and was identical in both groups. An additional seven HIV-1 seroconvertors were identified during the 6-month study period. Two of these individuals were initially HIV-Ag positive; 3/7 were consistently HTLV-I Ab reactive.
Conclusions. (1) Among the HIV-Pos and HIV-Neg subgroups, no difference in HTLV-I seropositivity was found. (2) HIV-Ag has a low prevalence rate in this group. (3) Among the 7 HIV-1 seroconvertors, there appears to be no change in HTLV-I serostatus.

Th.B.O.59 RELATIVE SPECIFICITY OF TWO EIAs FOR ANTIBODIES TO HTLV-I

Fang, Chyang* ; Akins, R.*; Le, P.*; Porter, L.*; Leete, J.** Lee, H.** and 40 American Red Cross Blood Services Regions.
*American Red Cross, Rockville, MD, **Abbott Laboratories, Abbott Park, IL.

Objective. Using Western blot (WB) and radioimmunoprecipitation assay (RIPA) to compare the relative specificity of 2 EIAs for antibodies to HTLV-I.
Methods. Donor sera originally found repeatedly reactive (RR), 171 (Group I) by Abbott EIA and 25 (Group II) by Du Pont EIA,in 40 different laboratories were retested by 2 EIAs and by WB.
Results.

	WB Bands	No. Samples Tested	No. Abbott EIA Reactive	No. Du Pont EIA Reactive
Group I:	None	52	43	16
	p19 only	29	24	28
	p24 only	36	33	22
	p19/p24	36	33	33
	p19/p24/gp46	19	19	19
Group II:	None	16	0	5
	p19 only	6	0	5
	p24 only	3	0	1

Six of 19 randomly selected samples from Group I and none of the 9 with WB p19 or p24 from Group II showed gp68 reactivity by RIPA.
Conclusion. Abbott EIA was more specific: 70% of RR samples showed ≥1 band on WB and 32% showed a gp68 band on RIPA compared to 36% and 0% for samples by Du Pont EIA, respectively. Furthermore, Abbott EIA was more reproducible: 89% of originally RR samples were still reactive as compared to 44% of Du Pont EIA RR samples.

M.B.P.1

IN UTERO HIV1 TRANSMISSION IDENTIFIED THROUGH PCR.

Valérie, Courgnaud*; Laure, F.* ****; Barin, F.**; Goudeau, A.**; Brossard, A.***; Bréchot, C.* and The Paris-Tours Collaborative group on perinatal HIV transmission**.
*INSERM U.75 CHU Necker, Paris, **Laboratoire de Virologie Tours (CNRS UA.271), ***Centre d'Hémobiologie périnatale, Paris, ****Diagnostics Pasteur, Marnes la Coquette, France.

Objective. To investigate the possibility of in utero HIV transmission.
Materials. 33 fetuses obtained from HIV1 positive mothers at 16 to 24 weeks of gestation. 3 fetuses were obtained at 16-18 weeks by hysterotomie. Thymus and spleen were dissected and analyzed separately. PBL of 30 mothers were available.
Methods. PCR for HIV1 DNA detection with 40 cycles and 3 sets of primers (Pol and Env genes).
Results. HIV1 DNA sequences were detected in 19/31 thymus and 22/33 spleen fetuses samples. Positive results were obtained in fetuses from 16 to 22 weeks.HIV1 DNA unambiguously scored positive in 2/3 thymus and spleens obtained by hysterotomie at 16-18 weeks. By using primers specific for the highly polymorphic cystic fibrosis locus, we have concurrently identified informative mothers; comparaison of the results obtained with these primers between mothers PBL and fetal tissues DNA did not show evidence for contamination of fetal tissue samples by infected mother cells.
Conclusions. This study indicates in utero HIV1 transmission, occuring even at an early stage of gestation. The likely high rate of transmission must be taken in account for strategies aiming to prevent perinatal infection.

M.B.P.2

ANTIGENEMIA p24 AND CD4 CELLS COUNTS IN HIV PREGNANT WOMEN.

Jean-François Delfraissy, D. Séréni, J.C. Pons, D. Mayer, V. Chambrin, Ph. Engelman, E. Papiernik, R. Henrion.
HIV Pregnancy study group, Paris, France.

Objective : To investigate the effects of pregnancy on virological and immunological parameters in HIV pregnant women, we studied the evolution of antigemia (Ag p24), anti p24 antibodies (Ac anti p24) and CD4 cells count during and after pregnancy.
Methods : Our study concern 3 group : group 1 HIV pregnant women (n = 97), group 2 HIV aborted women (n = 114), group 3 : non HIV pregnant women.
Results : CD4 cells are initially (first trimester) lower in group 1 (435 ± 72) and group 2 (452 ± 63), in comparaison with group 3 (885 ± 72). A slight decrease is observed during the pregnancy (third trimester) in group 1 (401 ± 83) and group 3 (772 ± 64). The mainfact is the lack of increased of CD4 observed at the 3th month of post partum in group 1 (332 ± 66) and group 2 (338 ± 72) contrasting with group 3 (933 ± 65). In group 1 (HIV pregnant women) HIV antigenemia are found in 8/80 at the first trimester, 24/78 at the 2 nd trimester, 14/72 at the 3th trimester. In the group 2 (women with induced abortion) HIV antigenemia is positive in 12/113 during the first 3 months. After the pregnancy antigenemia is respectively positive in 6/67 in group 1 and 8/102 in group 2. No modification of antibodies anti p24 was observed.
Conclusion : In HIV pregnant women, CD4 decrease is longer persistant in post partum, HIV ag p24 appears frequently during the 2nd trimester but is reversible. The role of these immunological and virological abnormalities in materno-foetal HIV transmission, and in the subsequent evolution of HIV infection in pregnant women are under investigation.

M.B.P.3

DISEASE PROGRESSION FOLLOWING PREGNANCY IN HIV SEROPOSITIVE WOMEN.

*MacCallum LR, *Cowan FM, ¯Whitelaw J, +Burns SM, *Brettle RP. *IDU; +Virology; City Hospital; ¯Immunology, Royal Infirmary, EDINBURGH, Scotland.

OBJECTIVE: To assess disease progression following pregnancy in HIV seropositive women.
METHOD: Of 107 HIV seropositive women infected between 1983 and 1985, 31 have had a pregnancy post seroconversion. Follow up has included monitoring clinical status, T4 lymphocyte count, IgG, IgA and HIV antigen at 6 monthly intervals.
RESULTS: Patients have been followed-up from 6 to 54 months with 18 having been followed for longer than 24 months. One has progressed to AIDS at 3 years post delivery and one has developed persistant oral thrush 2 years after delivery, the rest remain asymptomatic. T4 lymphocyte depletion to less than 200 has occurred in 2(6%) patients, 1 with AIDS and one other who is currently asymptomatic. IgG and IgA levels show no significant trend. 2(6%) patients have become antigenaemic but remain asymptomatic. There is no evidence of increased disease progression in this group compared with the nulliparous women or those who had pregnancies prior to seroconversion. In fact the nulliparous group are clinically worse possibly as a consequence of continued injection drug use.
CONCLUSION: Unlike others we have not observed an excess of post pregnancy disease progression. However, these are first pregnancies and none of the children have developed AIDS.

M.B.P.4

PREGNANCY ARISING IN HIV INFECTED WOMEN WHILE BEING REPETITIVELY COUNSELED ABOUT "SAFE SEX".

Kaplan, Mark H., Farber B.,Hall W.H.,Mallow C, O'Keefe C, Harper RG. North Shore University Hospital, Cornell University Medical College,Manhasset , N.Y.

Objective: To study the epidemiologic features of women who became pregnant after learning their HIV+ status
Methods: 151 women who were of child bearing age have been followed after they were found to be antibody + to HIV-1. A registry has been maintained of women who become pregnant after knowledge of their antibody status and after discussions about "safe sex".
Results: Of 80 surviving women from 88 IVDU's, 6 became pregnant one time and 1 2x. Of 43 surviving women from 46 women who acquired disease heterosexually, 3 became pregnant 1 time. No women of 11 surviving women from 17 who acquired disease from other means (6 transfusional, 3 Caribbean, 8 unknown male) became pregnant. 4/11 of women became pregnant even though they were taking zidovudine and were counseled several times about "safe sex". One patient's pregnancy was ectopic , 2 delivered full term children, one is carrying the pregnancy to term. 7 had termination of pregnancy. Pregnancy occurred even with low helper cells (<200 cells/mm3) in 5.
Conclusion: Pregnancy continues to occur frequently (11/134) even after women learn about their HIV status. Improved techniques about "safe sex" must be developed.

M.B.P.5

Failure of Targeted Screening to Identify HIV+ Pregnant Women.

Barbacci, Marguerite; Quinn T; Kline, R; Repke, J; Chaisson, R. The Johns Hopkins University, Baltimore, Maryland U.S.A.

Objective. To assess a targeted HIV screening program for women attending an inner city prenatal clinic.
Methods. All women attending the Johns Hopkins Hospital prenatal clinic between 2/87 and 1/89 completed a questionnaire to assess HIV risk behaviors. HIV testing was offered to women with acknowledged risk factors. Testing was available to women without acknowledged risk factors, but was not encouraged. Sera from rubella specimens, were obtained from women not voluntarily tested for HIV, and tested anonymously for HIV antibodies.
Results. 1416 women were enrolled in the clinic and evaluated. The median age was 23 years (range 16-43), 86% were black and 80% single. HIV risk behaviors were reported by 241 (17%) women; 54% were partners of intravenous drug users(IVDU), 30% were IVDUs, 10% had received transfusions before 1985, 4% were partners of bisexual or known HIV+ men and 2% reported prostitution. 166/241 (69%) women with risk factors consented to HIV testing; 19 (14.3%) were HIV+. 185 women denying risk factors requested testing; 9 (4.9%) were HIV+. 473 specimens were available for anonymous testing; 136 (28.8%) from women with acknowledged risk factors. Six specimens from this sampling tested seropositive, all from women without risk factors. Overall, 34 (4.1%) of 824 pregnant women tested positive for HIV. 15 (44%) of the seropositive women had no acknowledged risk factors for HIV infection.
Conclusion. These data suggest that targeting HIV screening to pregnant women who acknowledge risk factors will fail to identify a substantial number of infected women in urban settings. HIV screening, counseling and education should be made available to all patients as part of routine prenatal care.

M.B.P.6

PREGNANCY AND ACCELERATION OF HIV-RELATED ILLNESS

Deschamps, Marie-Marcelle*, Pape, J.W.**, Madhavan, S.**, Johnson,W.D.Jr*** *GHESKIO, Port-au-Prince, Haiti and **Cornell University Medical College, NY, NY, U.S.A.

Objective To study the effect of pregnancy on the development of HIV-related illness among seropositive asymptomatic women in Port-au-Prince, Haiti.
Methods A prospective study of 178 HIV-seropositive asymptomatic women of child-bearing age (15-45 years) was undertaken from 1983 to 1988. During the study period, 34 women were pregnant — 15 at time of study entry and 19 conceived during the follow-up period. There were 31 live births.
Results The 34 pregnant women (PW) were compared with the 144 non-pregnant women (NPW) with regard to the development of HIV-related illness. For the entire cohort, mean age was 29 years, gravidity 2.4, parity 2.1 and follow-up a mean of 21.4 ± 14.3 mo. PW and NPW were comparable in these parameters and in their socioeconomic status. During the study period, 16/34 (47%) PW and 37/144 (26%) NPW developed AIDS or HIV-related illness (x^2=5.03, p=0.025) The illness rate for PW (280/1000 person-years) was not significantly higher than that of NPW (184/1000 person-years). Illness developed in 5/16 PW during pregnancy (mean, 5th month) and in 11/16 a mean of 6 months postpartum. The cumulative proportion of women becoming pregnant increased from 12% to 29% for years 1 to 5 (survival analysis). Similar analysis showed the cumulative annual percentages of NPW developing symptoms at years 1 through 5 of follow-up is 12,25,35,46, and 53% and for PW is 3,32,53,53, and 84%.
Conclusion Pregnancy in asymptomatic HIV-seropositive women is associated with an accelerated development of AIDS or HIV-related illness during pregnancy and in the postpartum period.

M.B.P.7

FACTORS INFLUENCING MATERNAL DECISION-MAKING REGARDING PREGNANCY OUTCOME IN HIV INFECTED WOMEN

Wisnia, Andrew; Buoti, C.; Douglas, C.; Cabat, T. and Rubinstein, A.
Albert Einstein College of Medicine, Bronx, N.Y. U.S.A.

Objective: To determine the factors which influence HIV infected pregnant women to complete or terminate their pregnancy.
Methods: Thirty three HIV infected pregnant women were evaluated for factors involved in decision making regarding their pregnancy outcome. An elective termination of pregnancy (TOP) was medically available for the 22 (67%) women who were identified prior to 24 weeks of gestation. All women were aware of their HIV status and received comprehensive obstetrical and medical care as well as family counseling.
Results: Six of 22 women (27%) who were eligible for TOP chose to terminate their pregnancy electively. Of 11 women who developed HIV associated symptoms before 24 weeks of gestation, 4 elected TOP (36%). Seven of 33 (21%) had previously mothered HIV infected children. Six of 7 (87%) of these women chose to complete the current pregnancy. There was no difference in the number of previous abortions, maternal health, socioeconomic conditions, marital status, education or previous history of sexually transmitted diseases between those women whose pregnancies resulted in an elective TOP or those who chose to continue their pregnancy.
Conclusion: Neither the presence of an HIV infected older child nor HIV associated symptoms in HIV infected pregnant women appear to influence decision making concerning termination of pregnancy.

M.B.P.8

THE EFFECT OF PREGNANCY ON PROGRESSION OF HIV-RELATED DISEASE

Schoenbaum EE, Davenny Katherine, Selwyn PA, Hartel D, Rogers M**, NYC HIV Perinatal Transmission Collaborative Study* et al.
Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, New York, *New York City Department of Health, New York, NY and **CDC, Atlanta, Georgia, USA.

Objective. To study the effect of pregnancy on progression of HIV infection.
Methods. Since 9/85 141 HIV infected childbearing-aged women from a methadone program enrolled in an HIV natural history study had serial T-cell subsets, physical exams and interviews about demography, sexual, medical/obstetric history since 1978. The number of pregnancies since 1978 ending in livebirths (LB), baseline CD4 and CD4/CD8, onset and duration with HIV-associated constitutional symptoms (Sx) prior to oral thrush (OT)/AIDS were examined relative to the development of OT/AIDS during follow-up (F/U).
Results. Of 141 (30% black, 56% Hispanic, 14% white) mean F/U was 2.6 yrs. None developed AIDS during pregnancy. Development of HIV related illness by LB is shown.

	No LB	1 LB	≥2 LB (range 2-4)
	n=56	n=36	n=49
Asymptomatic	25 (45%)	20 (56%)	20 (41%)
HIV assoc. Sx	13 (23%)	14 (39%)	17 (35%)
OT/AIDS	18 (32%)	2 (5%)	12 (24%)

There was no difference in the mean duration of Sx for women with no LB (1.8 yrs.) and those with LB (2.4 yrs) (p>.05). On regression analysis, OT/AIDS was predicted by earlier onset and longer duration of Sx (p=.0001) controlling on CD4 <400/mm3 and CD4/CD8 <1.0, and was not predicted by LB (p=.59).
Conclusion. These data suggest progression of HIV disease to oral thrush or AIDS is not associated with pregnancy.

M.B.P.9

PHARMACOKINETICS(PK) OF ZIDOVUDINE(ZDV) IN HIV+ PREGNANT WOMEN

Watts,Heather;Brown,Z.;Tartaglione,T.;Opheim,K.;Coombs,R.;
Burchett,S.;et al. University of Washington, Seattle, WA, USA.

Objective: To evaluate ZDV Pk in pregnancy and postpartum.
Methods. In an ongoing study, ZDV Pk were studied several times during the second and third trimester and postpartum in 3 women on oral ZDV, 200mg every four hours (10-15mg/kg/day). Multiple blood samples were obtained and ZDV conc. were measured by HPLC. Pk were analyzed using noncompartmental analysis. CBC with red cell indices, T-lymphocyte subsets, plasma and lymphocyte HIV cultures, and renal and liver function studies were done monthly.
Results.

	Gestational week			2 wk
	13-26(n=3)	27-36(n=5)	>36(n=3)	Post(n=1)
$T^{1/2}$(hr)	1.8 ± 1.0	1.1 ± 0.4	1.1 ± 0.1	0.9
C_{max}(mg/L)	0.6 ± 3.0	1.4 ± 1.0	1.5 ± 0.7	1.1
AUC(mg/Lxhr)	1.1 ± 0.06	1.3 ± 0.4	1.1 ± 0.3	1.89
FxTBC(L/kg/hr)	2.2 ± 0.2	2.4 ± 0.8	2.5 ± 0.5	1.2
$FxVd_{ss}$(L/kg)	4.5 ± 0.3	3.2 ± 0.8	3.3 ± 1.2	1.7

Cord serum ZDV levels ranged from 86 to 127% of the maternal levels. The $T^{1/2}$ of ZDV in the neonates ranged from 9 to 23.3 hours. No symptoms or lab abnormalities required a reduction of dosage. None of the babies manifested clinical or laboratory abnormalities in the neonatal period; although one baby was delivered at 36 weeks gestation by cesarean section for oligohydramnios and fetal distress.
Conclusions. ZDV Pk in pregnant women were similar to other adults except Vd_{ss} was increased. No unexpected toxicities were observed in mothers and neonates. Significant transplacental passage of ZDV was observed.

M.B.P.10

KNOWLEDGE OF HIV SEROSTATUS AND PREGNANCY DECISIONS.

Barbacci, Marguerite; Chaisson, R; Anderson, J; Horn, J. Johns Hopkins University, Baltimore, Maryland, U.S.A.

Objective: To describe pregnancy decisions among 89 HIV + women attending clinics at the Johns Hopkins Hospital.
Methods: Retrospective review of pregnancy decisions from records of 89 HIV+ women: 34 women seeking prenatal care and 55 women attending an HIV infection clinic for women.
Results: Mean age of women 24.5 years (range 19-38 years). 80% black, 18% white, 2% other. Risk factors for HIV infection: 40% intravenous drug use (IVDU), 23% IVDU sexual partner, 11% transfusion, 4% bisexual or HIV+ partner, 2% prostitution. 76/89 (89%) had previously been pregnant with 60% having ≥2 living children. Seropositivity was discovered in 36(40%) women during pregnancy, 10 of whom were identified ≤ 20 weeks gestation. Two women had elective abortions(14 and 18 weeks), one had a spontaneous abortion at 12 weeks gestation, and 7 women opted to continue their pregnancies, 6/7 delivering term infants. 14 women (16%) became pregnant after learning they were HIV+. None of these women was using contraception. One woman who delivered a term infant had an elective abortion at 10 weeks of a subsequent pregnancy. The remaining 13 women continued their pregnancies with 12/13 delivering term infants.
Conclusions: Knowledge of HIV infection was not associated with pregnancy termination or prevention of subsequent pregnancy. In light of risk of perinatal transmission and possible acceleration of HIV infection during pregnancy, education, counseling and specialized obstetrical and medical services for women with HIV infection are needed.

M.B.P.11

IMMUNOHISTOCHEMICAL DETECTION OF HIV-ASSOCIATED ANTIGENS IN FORMALIN-FIXED NEONATAL PLACENTAS

Eitelbach, Florian*; Jimenez, E.*; Huang, Z.*; Unger, M.*; Wagner, G.*; Schäfer, A.**.; Grosch-Wörner, I.***
*Institute of Pathology, Department of Pediatric Pathology and Placentology; **Department of Obstetrics; ***Department of Pediatrics, Freie Universität, Klinikum Rudolf Virchow, Berlin, Federal Republic of Germany.

Objective. Detection of intrauterine HIV-infection in birth placentas of HIV-exposed pregnancies.
Methods. 1. 51 formalin-fixed neonatal placentas (22 of them with additional frozen tissue) of HIV-positive mothers. 2. Application of
a: monoclonal anti-HIV antibodies (Du Pont Anti-HTLV-III p24, product 9283/7053; Niedrig anti-p24, anti-p17);
b: various macrophage markers for the typification of the antigen profile of Hofbauer cells (placental macrophages).
Results. 1. Detection of HIV antigens in Hofbauer cells of 23 formalin-fixed placentas. 2. Positive reaction of Hofbauer cells (HC) with anti-CD4, p150/95, MAC 387; a subgroup of HC reacting with anti-CD1 and anti-HLA-DR. No demonstration of CD8, Pan B and DRC.
Conclusions. 1. HIV antigens can be localized in Hofbauer cells of formalin-fixed placentas. The antigen profile of HC corresponds to that of epidermal Langerhans cells. 2. HIV-infection of HC correlates to clinical signs of infection in the child, but up to now placental infection is more frequent than the latter. 3. Therefore, placental infection indicates an increased state of risk of the newborn but does not prove infection.

M.B.P.12

HIV SEROPREVALENCE IN AN INNER CITY OBSTETRIC POPULATION.

Johnson, John P., Watkins, S., Hines, S., Richardson, D. and Alger, L. University of Maryland School of Medicine, Baltimore, Maryland. USA.

Objective. To determine the seroprevalence of HIV infection in an inner city maternity population.
Methods. All women presenting to obstetric clinic were provided a questionnaire regarding HIV risk factors. The type and duration of risk factor was recorded and HIV testing was performed after informed consent and counseling.
Results. Four percent of the population indicated either sexual and/or drug use risk factors. Of this 4%, 24% were seropositive. Women indicating drug use had a seroprevalence rate of 24%, those with sex partners who were drug users had a 7% seroprevalence rate, those women who admitted to both risk factors had a 33% seroprevalence rate. Women whose risk factor occurred strictly before pregnancy had a 9% seroprevalence rate. Those whose risk factor only during pregnancy had a 13% seroprevalence rate and those who had risk factors occurred both before and during pregnancy had a 40% seroprevalence rate.
Conclusion. A program of self-identification in inner city maternity population yielded an overall 1 % seroprevalence rate. A drug use history was greater risk for HIV infection than sexual history. Duration of risk behavior and recency of risk behavior appeared to increase risk for HIV infection. Screening for type and timing of risk factor may help to identify a particularly high risk population for HIV infection.

M.B.P.13 PHARMACOKINETICS OF ZIDOVUDINE IN THE NEWBORN MACAQUES

Unadkat, Jashvant D., Lopez-Anaya, A., Schumann, L.A., and Smith, A.L.*
Schools of Pharmacy and *Medicine, Univ. of Wash., Seattle, WA.

Objective. The incidence of HIV infection in children is increasing. Administration of zidovudine (ZDV) to children (> 14mo. of age) with AIDS has already been shown to be of therapeutic benefit (1). Initiating ZDV therapy at an earlier age may increase these benefits further. In this regard, we have investigated the effect of age on the pharmacokinetics of ZDV in the newborn Macaca nemestrina.
Methods. ZDV was administered as a single IV bolus dose of 5mg/kg to newborn Macaca nemestrina during 1, 2, 4, 8, and 16 weeks of life. Blood samples were obtained frequently over the next 3h. Urine was collected over 24h. ZDV and ZDVG (the glucuronide metabolite of ZDV) in both plasma and urine were assayed by a modification of a previously published HPLC method (2).
Results. Pharmacokinetic parameters of ZDV were estimated as a function of age. The clearance of ZDV in two newborns, during week 1 of life, was found to be significantly smaller (4.85, 8.12 ml/min/kg) than that in adults (26.34 ± 2.56 ml/min/kg) but rapidly approached the latter within 6-8 weeks of life. The 24h urinary molar ratio, ZDVG/ZDV, was also smaller during week 1 of life (0.4, 0.57) than that in adults (0.86, 0.77).
Conclusions. Clearance of ZDV in the newborn is significantly smaller than that in the adults primarily due to deficiency in the ability of the newborns to metabolize ZDV to ZDVG. However, maturation of the enzyme mediating this metabolism appears to be rapid. If human newborns have a similar deficiency in the metabolism of ZDV, the dose of ZDV for this population will need to be adjusted. Similar experiments in further animals are in progress.

M.B.P.15 TRANSPLACENTAL TRANSFER OF ZIDOVUDINE

Unadkat, Jashvant D., Lopez-Anaya, A. and Schumann, L.A.
School of Pharmacy, University of Washington, Seattle, WA.

Objective. Administration of zidovudine (ZDV) to HIV positive pregnant women may be beneficial to both the mother and her unborn baby. Based on this premise, experiments were conducted to ascertain if ZDV crosses the placenta in the near-term pregnant macaque, and, if it does, whether ZDV accumulates in the fetus.

Methods. ZDV was administered as a constant rate IV infusion, to two near-term pregnant macaques (155d and 165d), so as to obtain a steady-state plasma concentration of about 1 µg/ml. Blood samples were obtained simultaneously from the dam and the fetus (from the umbilical vein) to estimate the steady-state plasma concentration ratio (Cssr=Cssd/Cssf) between the dam (Cssd) and the fetus (Cssf). Plasma concentrations of ZDV and its major metabolite, the glucuronide (ZDVG), were determined by HPLC (1).

Results. The total plasma clearance, and the ratio, Cssr, for the two mother-fetus pairs studied were estimated as 29.0, 21.1 ml/min/kg, and 0.92, 0.74 respectively.

Conclusions. ZDV, when administered to near-term pregnant macaques, crosses the placenta readily and does not accumulate in the fetus. Similar experiments in further animals are in progress.

M.B.P.17 ULTRASONOGRAPHIC ASSESSMENT OF FETAL GROWTH AND MORPHOLOGY IN HIV-1 POSITIVE PREGNANT WOMEN

Boucher,Marc*;Samson,J.*;Delage,G.*;Hankins,C.**; Fauvel,M.***; Lapointe,N.*. *Hôpital Ste-Justine,Université de Montréal; Montréal,Québec, Canada, **DSC, Montreal General Hospital,McGill University, Montréal,Québec, Canada, ***LSPQ, Ste-Anne-de-Bellevue,Québec,Canada.

Objective.The evaluation of intrauterine growth and morphology of fetuses from HIV-1 + pregnant women in light of the suggested existence of a syndrome combining growth failure and craniofacial dysmorphism in infants with HIV-1 infection.
Methods.Ultrasonography(US) is a reliable method for diagnosis of growth failure and some cranial/facial anomalies in utero.Serial scans were done on prospective patients while regular scans were reviewed from retrospective patients (Siemens SL-1,3.5MHz linear array).In our ongoing study 10 HIV-1 + pregnant women (4 retrospective, 6 prospective) had a total of 24 scans.
Results.All measures (biparietal diameter:24/24, head circumference:13/13, abdominal circumference:18/18 and femur length:24/24) were within 2 standard deviations(SD) from the mean for gestational age for our population. Cerebellar transverse diameter was obtained 9 times from 4 fetuses and outer orbital diameter was measured on 6 fetuses on 13 occasions.All those measures fell within normal range (±2SD).No other anomalies were noted.
Conclusion.Our study suggests that US is a unique and readily available instrument for assessment of fetal growth/morphology in fetuses of HIV-1 + mothers.Our preliminary results suggest that in our population, growth retardation is not a prominent feature in fetuses from HIV-1 + mothers and that growth is harmonious in all aspects in those fetuses. Finally, dysmorphic growth of cranial structures does not seem to occur in utero.

M.B.P.14 A PROSPECTIVE STUDY OF HIV IN PREGNANT WOMEN.

Di Lenardo, L.; Truscia, D.; Giaquinto, Carlo and Grella, P.V.
University of Padua, Padua, Italy.

Objective. The aim of the study was to see whether pregnancy, in sero-positive women, could have adverse effects on the mother especially if it increased the risk of developing disease in the period following delivery.
Methods. Two groups of drug-addicted pregnant women - one group being sero-positive (28 cases) and the other sero-negative (16 cases) - were followed in a prospective fashion during pregnancy. The usual biochemical and biophysical workup and monitoring of pregnancy were carried out. Furthermore the following lab data were requested: T4/T8 and their ratio, immunoglobulins total and fractioned serum proteins, leucocite count.
Results. There has not been a significant increase in the number of pathologies of obstetrical pertinence in the sero-positive women. If, on the one hand, there was reduced and/or inverted T4/T8 ratio in 2/3 of the cases, the remaining parameters stayed within the normal range. The newborns were not significantly S.G.A. Trasmission of HIV occured in 30% of cases.
Conclusion. In the years following pregnancy our patients did not show a worsening of the disease; this was ascertained by our follow-up.

M.B.P.16 PREGNANCY AND HIV INFECTION: AN EXPERIENCE ABOUT 15 CASES

Castelli F.*,Chiodera A.*,Tarantini M.§,Prati E.§,Bianchi UA§ Carosi G*, *Dpt Infectious.Trop.Dis.,§Dpt Obs.Gynec., Univ.Brescia, Italy.

Objective Recent reports have suggested that pregnancy may accelerate the progression of HIV infection when the baseline clinical status is severe, but in preclinical stages. To contribute in clarifying the matter, the present study focuses on 15 HIV seropositive women (14 IVDA, 1 sexual contact; mean age=26.3 yrs) who were prospectively monitored before, during and after one pregnancy (cases), as compared to 30 HIV seropositive women (23 IVDA, 7 sexual contacts, mean age = 26.5 yrs) without pregnancies and followed-up for a similar period (controls).
Results According to CDC staging (1987), 4/15 cases (27%) showed a progression from stages II to III, as compared to 6/30 control women (20%; 5 from stages II to III and 1 from stage II to IVc2). The median follow-up period resulted to be 9 (4-37) for cases and 13.5 (3-43) months for controls. A lyfe-table analysis of these data was then approached; by 12 months 20% of cases and 4% of controls would show a clinical progression; by 24 months, the corresponding figures would be 40% (cases) and 28% (controls)
Conclusion According to our preliminary data, the hypothesis that pregnancy may affect the progression rate of HIV infected women cannot be ruled out, even if no AIDS cases were observed. Progression to CDC stage III in cases seemed to be somehow faster (life-table analysis). A prolonged follow-up study on larger cohorts of women is needed to reach definitive conclusions.

M.B.P.18 HIV-ANTIGENS CAN BE DEMONSTRATED IMMUNOHISTOCHEMICALLY IN FORMALIN-FIXED MATERIAL FROM THERAPEUTIC ABORTIONS OF HIV-EXPOSED PREGNANCIES

Kitelbach, Florian*; Unger, M.*; Huang, Z.*; Jimenez, E.*; Wagner, G.*; Schäfer, A.**
*Institute of Pathology, Department of Pediatric Pathology and Placentology; **Department of Obstetrics, Freie Universität, Klinikum Rudolf Virchow, Berlin, Federal Republic of Germany.

Objective. 1. Detection of HIV-associated antigens in formalin-fixed tissues. 2. Frequency and earliest period of morphological demonstration of HIV-infection in embryonal/fetal organs, predisposition of certain organs for infection.
Methods. 1. 10 embryonal placentas and 4 embryos (7^{th}-12^{th} week of gestation). 2. 12 fetal placentas and fetuses (15^{th}-27^{th} week of gestation). Demonstration of HIV-associated antigens by monoclonal antibodies (mab), one of them commercially available (Anti-HTLV-III p24, Du Pont 9283/7053), the others gifts of Dr. Niedrig, Robert Koch Institut/Berlin (anti-p24, anti-p17). Prior to the application in abortions the mabs were tested in formalin-fixed HIV-infected and non-infected H9 cell lines (Dr. Pauli, Robert Koch Institut) and in biopsy/autopsy material of lymph nodes.
Results and Conclusions. 1. HIV-associated antigens can be demonstrated in formalin-fixed abortion material (8/22). 2. Earliest demonstration of HIV antigens in the 16^{th} week of gestation. 3. The Hofbauer cell (fetal macrophage) plays a central role in the transplacental chain of infection from mother to fetus.

M.B.P.19

Seroprevalence of HIV-1 and HTLV-I among pregnant women in Newark, NJ.

Connor, E,**; Denny,Thomas,*; Goode, L,* Niven, P,*; Oxtoby, M,***; Oleske, J*, et al.
*UMD-NJ Medical School, Children's Hospital of New Jersey**, Newark, NJ and CDC, Atlanta, Ga*** USA.

Objective. To determine the seroprevalence of HIV-1 and HTLV-I in pregnant women delivering at a University Hospital in Newark, NJ, which serves primarily a local, inner city minority population (80% black, 12% hispanic and 8% white).
Method. Between 9/87 and 9/88 samples of serum were obtained at the time of delivery from maternal, cord, or infant blood. Samples were anonymously tested for the presence of antibodies to HIV-1 and HTLV-I by using ELISA (Abbott) and Western Blot (Biotech/Dupont).
Results: A total of 2,619 deliveries occurred and 2,205 samples were available for HIV-1 (84%) and 2,067 (79%) for HTLV-I testing. HIV-1 ELISA was reactive in 6.2% (136) and Western blot was reactive in 98/136 (72%) yielding a confirmed seroprevalence of 4.4% for HIV-1. HTLV-I ELISA was reactive in 2.1% (44) and Western blot was reactive in 27/44 (61%) yielding a confirmed seroprevalence of 1.3% for HTLV-I. Of the HIV+, 10 (10.2%) were also HTLV-I+.
Conclusion. Women delivering at the institutions studied are at risk of 1/22 for HIV-1, 1/77 for HTLV-I and 1/220 for co-infection. These data suggest that vertical transmission to newborns of HIV-1 and HTLV-I are important risks in our communities.

M.B.P.20

PATHOLOGY AND HIV EXPRESSION IN TERM PLACENTAS FROM SEROPOSITIVE WOMEN.

Chandwani,Sulachni; Greco,M.A.; Mittal,K.; Krasinski,K.; Borkowsky,W. New York University Medical Center & Bellevue Hospital Center, New York, NY, U.S.A.

Objective. To compare the pathology of term placentas from seropositive HIV infected and seronegative women using routine histologic, immunohistocytochemical, and in situ nucleic acid hybridization techniques.
Methods. Term placentas of seropositive and seronegative women were evaluated by hematoxylin and eosin (H & E) staining for evidence of vasculitis (VA), villitis (VI), chorionitis (CH), and chorioamnionitis (CA). They were also examined by immunoperoxidase (IP) staining using monoclonal anti-p24 antibody. Decidua (DE), trophoblasts (TR), membranes (ME), and uterine glands (UG) were evaluated. Some of these were tested using IP and in situ nucleic acid hybridization (NAH) techniques using an RNA probe complementary to the 3'LTR and envelope region of HIV-1.
Results.

	Histology				Immunoperoxidase				IP+NAH
	VA	VI	CH	CA	DE	TR	ME	UG	TR
Seropositives	1/45	0/45	24/34	1/34	0/24	1/41	0/18	0/7	1/12
Seronegatives	0/21	0/21	9/17	0/17	0/10	0/19	0/7	0/4	0/8

Conclusion. HIV infection does not appear to cause significant pathologic abnormalities in the term placenta. HIV antigens can be identified rarely in trophoblastic tissue. HIV nucleic acid can be found in these trophoblastic cells also containing HIV antigen. Examination of the term placentas from HIV infected women has failed to clarify the mechanism of transmission of this virus from mother to fetus. Conceivably,tissue from earlier gestational placentas may be more informative.

M.B.P.21

DIFFERENCES IN IMMUNOSUPPRESSION DURING PREGNANCY IN HIV-INFECTED WOMEN

Schäfer, Axel*; Friedmann, W* and Schwartländer, B.**
* Dept. of Obstetric and Gynecology, Freie Universität Berlin, FRG
**AIDS-Center, Bundesgesundheitsamt, Berlin, FRG.

Objective: To evaluate the natural course of HIV-infection during pregnancy
Methods: In a comparativ study 54 HIV-infected and 50 HIV-negative pregnant women were investigated every 2 - 4 weeks on clinical status and the following immunological parameters: T-cell counts: CD2, CD4, CD8; Immunoglobulines: IgG, IgM, IgA, IgE; Circulating-immunkomplexes: IgG, IgM.
Results (selection): On the basis of the immunological parameters the investigated collective of HIV-infected pregnant women was divided into 4 groups: Group 1: no abnormal immunological findings. Group 2: CD4/CD8 ratio < 0.8, CD4-cells > 400. Group 3: CD4-cells 250 - 400. Group 4: CD4-cells < 250.

	Controls n=50	Group 1 n=11	Group 2 n=25	Group 3 n=13	Group 4 n=5
CD4 decr.>10%	27	9	23	12	5
CD4 decr.>40%	0	3	12	9	2
CD2 decr.>40%	0	2	9	8	5

Discussion: The greatest extend of immunosuppression during prenancy in HIV-infected women was seen in group 2 and 3 (decrease of CD4-cells > 40%) and group 4 (decrease of CD2-cells > 40%). The majority of women showed a postpartal regeneration. 6 women had a continous loss of CD4-cells after delivery.

M.B.P.22

EFFECT OF PREGNANCY ON THE PHARMACOKINETICS OF ZIDOVUDINE

Unadkat, Jashvant D., Lopez-Anaya, A. and Schumann, L.A.
School of Pharmacy, University of Washington, Seattle, WA, U.S.A.

Objective. The incidence of HIV infection in pregnant women is increasing. Thus, administration of zidovudine (ZDV) to pregnant women may be of benefit to them and to their unborn babies. To determine the effect of pregnancy on the pharmacokinetics of ZDV, experiments were conducted on macaques (Macaca nemestrina) at term and after delivery.

Methods. ZDV was administered as a single IV bolus dose (10mg/kg) to two macaques, at term and 1 week after delivery. Blood samples were collected frequently over the next 4h. Urine was collected over 24h. ZDV and ZDVG (the glucuronide metabolite of ZDV) in both plasma and urine were assayed by HPLC (1).

Results. The total plasma clearance (CL), steady-state volume of distribution (Vss) and the terminal half-life of ZDV were estimated. At term, these parameters, for the two animals studied, were estimated as 24.6, 27.6 ml/min/kg, 903, 1314 ml/kg, and 37.4, 45.5 min respectively. In the non-pregnant status, these parameters were 27.8, 30.1 ml/min/kg, 727, 1256 ml/kg, and 39.9, 34.8 min respectively.

Conclusions. The pharmacokinetics of ZDV do not appear to be altered by pregnancy. Similar experiments in further animals are in progress.

1. Good S. *et al.*, J Chromatog. 431: 123-133, 1988.

Supported in part by March of Dimes Birth Defect Foundation (1-1135) and Burroughs Wellcome Inc.

M.B.P.23

SEROPREVALENCE IN A PREGNANT MULTIETHNIC POPULATION

O'Sullivan, Mary J., Fajardo, A; Ferron, P, Efantis, J. Sesk, C. Duthely, M. University of Miami, Miami, Florida, United States of America.

Objective. To determine HIV-1 seroprevalence by antibody status in women delivered at a medical center serving the indigent, multi-ethnic population of Miami, Florida, Florida, U.S.A.
Methods: From 7/1/88 to 12/31/88, patients admitted to the labor suite had extra blood drawn and stored for 24 hours or less. They were interviewed, counselled, and offered HIV antibody testing after delivery. The samples of those who refused or were discharged before interview were blinded. Information obtained directly from patients included demographics and the following risk factors: drugs (cocaine, crack, IV), sexual partners, bisexuality, prostitution, blood/factor transfusions.
Results: Of the 7,400 offered testing, 92.7% gave consent, of whom 2.3% were seropositive. Of the 3.7% refusing testing, 4.5% were HIV-positive (chi square analysis p <.013), suggesting a bias. Of the remainder, 2.0% were positive. The age distribution of the seropositives matched the obstetrical population. Teens were 16.5% of the seropositives (2.3% - <16 years old). Seropositive Black Americans predominated (58%), 52.25% were ≤25 years of age, compared to Haitians (30.37%), 57.6% were >25 years old (p <.0005) Seropositivity also correlated with drug use, multiple partners, and risk status, p <.0005 each. However, 45.6% of the seropositives had no admitted currently accepted risk factors.
Conclusions: Screening should be offered to all pregnant women, certainly in our population. Sexually active teenagers are at risk of infection, especially the Black American. While accepted risk factors are associated with seropositivity, no apparent risk factors account for almost half these infected patients, implying heterosexual transmission as the largest identifiable factor. Education for prevention should begin before sexual maturation.

M.B.P.24

A PROSPECTIVE STUDY OF THE MENTAL AND MOTOR DEVELOPMENT OF INFANTS BORN TO HIV INFECTED INTRAVENOUS DRUG USING MOTHERS

Kletter, Ron*; Jeremy, R.J.**; Rumsey, C.**; Weintrub, P.**; and Cowan, M.**.
*BAART-FACET, San Francisco,**University of California, San Francisco, USA.

Objective. To describe prospectively the mental and motor development of infants born to IV drug-using mothers exposed in utero to HIV.
Methods. Quarterly assessment on the Bayley Scales of Infant Development which yield a standardized Mental Development Index (MDI) and a Psychomotor Development Index (PDI). Three groups of infants: CONTROL (HIV-negative mother, N=15), INFECTED (HIV-positive mother, HIV-positive child, N=10), and UNINFECTED (HIV-positive mother, HIV-negative child, N=10).
Analyses. Comparison of MDI and PDI scores of the three groups at ages 3,6, 9,12, and 15 months: a) groups means, and b) individual developmental curves.
Results. INFECTED infants showed lower MDI and PDI means with age between 3 and 12 months, with some improvement at 15 months, in contrast to both non-infected groups which did not continue to decline. However, while the CONTROL group performed around normal MDI and PDI, the UNINFECTED group hovered about 1 standard deviation lower.
Individual developmental curves showed that among the best developing infants were 53% of the CONTROL, 10% of the INFECTED, and 20% of the UNINFECTED. Among the poorest, 7% were CONTROL, 70% were INFECTED, and 40% were UNINFECTED.
Conclusion. The mental and motor development of HIV infected children declines over the first 15 months of life. The mental and motor development of infants exposed prenatally to HIV but not infected is poorer than that of CONTROL children not so exposed.

M.B.P.25 INFLUENCE OF GESTATION ON HIV INFECTION.

BERREBI,Alain* ; PUEL,J.** , TRICOIRE,J.*** ; HERNE,P**** ; PONTONNIER,C.*.
*Services de Gynécologie-Obstétrique, Hôpital La Grave; **Service de Virologie, Hôpital Purpan; ***Service de Pédiatrie B, Hôpital Purpan, Toulouse; ****Association "Le Patriarche", Saint-Cezert, France.

Objective. In order to compare the influence of time alone to the influence of time plus pregnancy on infection with HIV, we report results of a three year follow-up of two groups of women. (A) : 60 HIV antibody positive, asymptomatic, pregnant patients (34 live births, 26 medically indicated abortions) (B) : 68 age and sex matched HIV antibody positive, asymptomatic patients without gestation.
METHOD. In these two populations, the following parameters were compared : clinical stage, sedimentation rate, white cell count, relative lymphocyte count, relative and absolute T4 lymphocyte count, the T4/T8 ratio, the serum level of IgA, and the presence of the P24 HIV antigene. These parameters were measured during pregnancy, at termination of pregnancy, and one, two, and three years thereafter.
RESULTS. No statisticly significant differences between the two groups were found. In 20 % of the pregnant population, we found a transient appearance of the HIV P24 antigene during pregnancy.
CONCLUSION. Over a period of three years, no difference in the progression of HIV disease was observed between a population with and one without pregnancy. The transient appearance of HIV P24 antigene during pregnancy, does not seem to be a poor prognostic marker for progression of HIV disease.

M.B.P.26 EFFECTS OF HIV INFECTION ON PREGNANCY.

BERREBI, A* ; KOBUCH, W.E.* ; PUEL, J.* ; TRICOIRE,J.***, HERNE,P.*** ; FOURNIE, A*

*Services de Gynécologie-Obstétrique, Hôpital La Grave; **Service de Virologie, Hôpital Purpan; ***Service de Pédiatrie B, Hôpital Purpan, Toulouse; ****Association "Le Patriarche", Saint-Cezert, France.

OBJECTIVE. We compared the complication-rate during pregnancy and the perinatal period among HIV antibody positive former drug addicts (group A), 68 HIV antibody negative present drug addicts (group B), and 3017 patients without a history of HIV infection or drug addiction (group C). The purpose of this study was to define the influence of HIV infection on pregnancy.
METHODS. We assessed the following parameters : fever during pregnancy, hydramnios, fetal malformations, fetal growth retardation, premature labor, the APGAR score, and postpartal complications.
RESULTS (in %).

	Fever	hydramn.	malform.	growth ret.	Prem. labor	Apgar < 7	postpart. complic.
A	16,2	5,4	5,4	10,8	16,2	10,8	2,7
B	7,4	1,5	5,9	25,0	14,7	8,8	2,9
C	2,3	1,4	2,6	8,7	4,2	6,0	3,2

CONCLUSION. HIV infection appears to have no influence on the course of pregnancy, and does not increase fetal mordidity. Complications such as fetal malformation, growth retardation, and premature labor seem to be more closely related to drug addiction and concomitant low socio-economic status, than to infection with HIV.

M.B.P.27 PREGNANCY OUTCOME IN WOMEN HIV INFECTION IN PUERTO RICO IN A POPULATION OF PREDOMINANT HETEROSEXUAL TRANSMISSION

Romaguera J.; Zorrilla C.; Díaz C.; Moscoso R.; De La Vega A.; Carrodeguas J. Puerto Rico, U.S.A.

Findings. The prevalence rate was 1.47%, the most common risk factor was being a sexual partner to an IV drug user (65%) followed by IV drug use by the patient (27%). The mean age was 24 and the mean gravidy was 3.3 . Most had stable relationships by marriage or consensual union 71%. The mean number of lifetime sex partners was 2.6 (excluding patients who were prostitutes). The most common prenatal complication was diabetes mellitus (12%) followed by preterm labor 18%. Smoking was reported by 58% of patients. Mean weight gain during pregnancy was 20 lbs. Cesarean section rate was 15%. Perinatal mortality was 9.5% and post-neonatal mortality 4.2%.

Mean birth weight was 2,909 g, although 41% of the babies weighed 2,500 g. 9% of the patients elected pregnancy terminantion and 30% underwent post partum sterilization. 7% of cases progressed to ARC/AIDS. Maternal mortality was also high (2.5%) and exclusived due to AIDS.

Conclusion. Perinatal as well as post-neonatal mortality is increased in the offspring of seropositive pregnant women. Maternal mortality is also increased significantly in this group of young women. Since the two maternal deaths occurred within one year post partum in women whose neonates had congenital pneumonia, we may identify infection of the fetus as a risk factor for development of over desease in the mother.

M.B.P.28 COMPARISON OF LIFESTYLES AND HIGH RISK SEXUAL BEHAVIOR BETWEEN HIV-SERO-POSITIVE AND HIV-SERO-NEGATIVE PREGNANT WOMEN

Zorrilla, C; Romaguera, J; Torres, J; Morales, L; Adamsons, K.
University of Puerto Rico School of Medicine, San Juan, Puerto Rico.

Objective. To compare the frequencies of different types of high risk sexual behavior and lifestyles during pregnancy in sero-positives vs sero-negatives to H.V.
Methods. Personal interviews obtaining sexual histories and risk factors were performed in 81 HIV positive and 67 sero-negative pregnant women.

Findings. Age, gravidity, marital status, weight gain during pregnancy and number of prenatal visits did not differ among groups.

Anal intercourse was significantly more common by sero-positive patients, while there were no differences in oral intercourse with or without ejaculation (22% vs 25%).

Cigarette smoking was significantly more frequent among the HIV positive women (56% vs 24%, as was the relative frequency of sexually transmitted diseases (25% vs 6%). Significantly more sero-positive pregnant women had risk factors for HIV transmission than sero-negatives (76% vs 9%). Of those with risk factors, more sero-positive women were sex partners of IV drug users (65% vs 3%).

M.B.P.29 Reproductive History (RH) of HIV Antibody Positive (HIV Ab+) Women Followed in a Prospective Study in Newark, NJ, USA

Schnack, Mary*, Goode, L*, Connor, E**, Holland, B*, Oxtoby, M***, Oleske, J*. UMD NJ Medical School*; Children's Hospital of NJ, Newark, NJ**; CDC, Atlanta, GA*** USA.

Objective. To describe reproductive hx of a cohort of HIV Ab+ women followed in a prospective study.
Methods. Pregnancy information on 43 HIV Ab+ women whose children are enrolled in a prospective study was obtained by interviewing mothers directly (n=30) or the child's guardian (n=13). Mean follow-up was 12 mo (range 2-20mo).
Results. Seven women had one subsequent pregnancy and 2 were pregnant twice.

Pregnancy	Mother	Pregnancy Status	Index of Child's age time of pregnancy
1	A	Terminated	12 mo
2	B	Terminated	4 mo
3	B	Terminated	18 mo
4	C	Terminated	8 mo
5	C	Continued	13 mo
6	D	Continued	4 mo
7	E	Continued	4 mo
8	F	Terminated	2 mo
9	G	Terminated	5 mo

Conclusion. Despite counseling for risks associated with HIV, a high percent of HIV Ab+ women in this cohort became pregnant an average of 8mo after delivering an HIV Ab+ child. Future studies will need to address knowledge of HIV seropositivity and its impact on rate of pregnancy among women in a high risk area for HIV.

M.B.P.30 DRUG ABUSE AND PREGNANCY: CONCOMITANT RISK FACTORS FOR HIV INFECTION

Weiner, Susan M.; Kaltenbach, K.A. and Finnegan, L.P.
Thomas Jefferson University, Philadelphia, Pennsylvania, U.S.A.

Women who are intravenous drug users or who are partners of intravenous drug users engage in behaviors that put them at high risk for developing human immuno deficiency virus infection. When the woman is pregnant, there is the additional problem of perinatal transmission to her unborn child. Data which included socioeconomic and psychological profiles as well as sexual and drug use habits was collected on 90 drug dependent pregnant women enrolled in a comprehensive treatment program in a study aimed at reducing HIV infection among IV drug abusing women and accordingly the perinatal transmission of AIDS. All the clients consented to confidential ELIZA tests on initial evaluation and every 3 months while pregnant. Psychosocial profiles revealed that 53% had been subjected to physical or sexual abuse; 11% were homeless; and 46% were adult children of alcoholics or children of substance abusers. Drug histories showed that these women were addicted an average of 10 years: 62.5% were polydrug abusers and 35% used cocaine alone; 39% of the women are current IV drug users. Of these 90 women enrolled, 4.5% came into the project HIV positive, but without symptoms of HIV infection. None of the other 95.5% who tested negative at the outset seroconverted while participating in the project. As a result of this project, it is apparent that counseling women with regard to these specific risk factors must continue to reduce the incidence of perinatal HIV infection.

M.B.P.31 EQUALLY POOR RESPONSE TO TETANUS VACCINE IN HIV SEROPOSITIVE AND SERONEGATIVE MOTHERS IN ZAIRE

Baende, E.*; Ryder, Robert*/**; Halsey, N.***; Donnenberg, A.***; Quinn, T.***. *Projet SIDA, Kinshasa, Zaire; **CDC, Atlanta, GA; ***Johns Hopkins University, Baltimore, MD, U.S.A.

Objective. To determine if current WHO recommendations (one dose in the last trimester if the mother has been vaccinated in the previous 3 years otherwise 2 doses with the last one at least 15 days before delivery) for use of tetanus toxoid vaccine (TTV) in pregnant women are appropriate for HIV(+) women in Zaire.
Methods. Before and after(at the time of delivery) TTV samples were obtained from 111 HIV(+) women and 207 HIV(-) women at a Kinshasa antenatal clinic. Absolute T4 lymphocyte counts (HIV(+) women only) and anti-tetanus antibody titers (ATAT) measured by an ELISA capable of detecting 0.0008 IU/ml, were determined on the paired blood samples. ATAT were classified as non-protective ((0.01 IU/ml), borderline (0.01-0.04 IU/ml) or protective ()0.04 IU/ml).
Results. Maternal pre- and post-ATAT by serostatus

	Before TT vaccine		After TT vaccine	
ATAT	HIV(+)	HIV(-)	HIV(+)	HIV(-)
Non-Protective	45%	26	15	13
Borderline	20	21	14	8
Protective	35	53 (p(.05)	29	19 (P=NS)

(p values compare pre-vaccination ATAT in HIV(+) and HIV(-) mothers and post-vaccination ATAT in the same groups)
In HIV(+) women, HIV-induced immunosuppression (ABS T4 counts) did not correlate with ATAT in pre- and post-vaccination determinations.
Conclusion. A total of 24% of the pregnant women (29% of 111 HIV(+) women and 21% of 207 HIV(-) women (P=NS) with documented appropriate receipt of TTV at a Kinshasa antenatal clinic had less than protective levels of ATAT at the time of delivery. Inability to document a difference in TTV response between HIV(+) and HIV(-) mothers suggests that current TTV practices should be reviewed for both groups of women.

M.B.P.32 CARACTERES EPIDEMIOLOGIQUES ET EVOLUTION CLINIQUE DE 45 PATIENTES ENCEINTES SEROPOSITIVES POUR LE VIH.

Parnet-Mathieu, F.*; Meyohas, M.C.**; Vincenti, O.***; Barrat, J.***; Eliaszewicz, Muriel** et Brossard, Y.*
* Centre d'Hémobiologie Périnatale;
** Service des Maladies Infectieuses, Hôpital St-Antoine;
*** Service de gynéco-obstétrique, Hôpital St-Antoine, Paris, France.

Objectif. Etudier les caractères épidémiologiques et l'évolutivité clinique de deux populations de femmes enceintes séropositives (grossesse menée à terme (G) et interruption médicale de grossesse (I.M.G.)) de juin 1986 à décembre 88. Patientes. L'étude concerne 20 G, 22 IMG, 2 FCS et 1 GEU. Toutes les patientes ont au moins un facteur de risque et sont suivies à la maternité de l'hôpital St-Antoine qui fait partie de l'enquête épidémiologique multicentrique parisienne. Résultats. Il n'y a pas d'augmentation du nombre de patientes entre 1987 et 1988 (19 et 20). Les toxicomanes dominent (24/45) dont la plupart sont d'origine française (20/24). La décision d'interruption de grossesse ne parait être influencée ni par la toxicomanie (11/23 G, FCS et GEU, 12/22 IMG) ni par la parité (multipare : 9/23 G, 11/22 IMG), ni par l'annonce de la séropositivité (13/20 G, 11/21 IMG). Le suivi clinique est mauvais pour des raisons socio-économiques. Parmi les patientes asymptomatiques, sur 18 G, 4 (22,2%) évoluent vers le stade IV du CDC en fin de grossesse et sur 20 IMG,5 (25%) évoluent vers ce stade dont un décès, dans les 6 mois qui ont suivi.Parmi les 4 patientes au stade IV (2 G et 2 IMG), il n'y a pas d'évolutivité clinique dans ce délai. Conclusion. Le fait d'être enceinte parait augmenter le risque de passage au SIDA. Il ne semble pas que ce risque soit diminué avec une IMG.

M.B.P.33 HIV-1 SEROPREVALENCE AND RISK BEHAVIOR ARE INCREASED IN PREGNANT WOMEN RECEIVING NO PRENATAL CARE

Dattel, Bonnie J, Hauer LB, Crombleholme W, Landers DV, Edison R, Sweet RL, et al; University of California, San Francisco, SF General Hospital, USA.

Objective: To assess HIV-1 seroprevalence and risk behavior in women receiving prenatal care (PNC) or delivering with no prenatal care (NC) at an urban county hospital in an area with a high prevalence of HIV-1.
Methods: Ongoing seroprevalence studies of pregnant women began in January 1988. All PNC and NC patients completed risk assessment/demographic questionnaires coded to sera anonymously tested for antibodies to HIV-1.
Results: As of January 1989, 178/1066 (16.7%) PNC and 31/65 (47.7%) NC patients reported ≥ 1 HIV-1 risk behavior.

Behavior (answered yes or maybe)	PNC: n = 1066	NC: n = 65
Self IVDU	30 (2.8%)	14 (21.5%)
Partner IVDU	98 (9.2%)	15 (23.1%)
Multiple Partners (≥ 5/yr)	72 (6.8%)	17 (26.2%)
Bisexual Partner(s)	68 (6.4%)	9(13.9%)
Hemophiliac/transfusion partner(s)	75 (7.1%)	8 (12.3%)
Self/Partner/Child AIDS or HIV +	47 (4.4%)	7 (10.8%)

HIV-1 seroprevalence was 0.7% in PNC and 1.5% in NC patients. All seropositives reported ≥ 1 risk behavior on the risk assessment questionnaire.
Conclusions: Women delivering with NC were more likely to report risk behavior for HIV-1 and had more than twice the HIV-1 seroprevalence as women with PNC (1.5% vs 0.7%). These data suggest that women with no prenatal care may be at increased risk for perinatal transmission of HIV-1.

M.B.P.34 DOES PREGNANCY INFLUENCE DISEASE PROGRESSION IN HIV POSITIVE WOMEN.

JeanFrançois Delfraissy, J.C. Pons, D. Séréni, V. Chambrin, D. Meyer, Ph. Engelman, E. Papiernik, R. Henrion.
HIV Pregnancy study group, Paris, France.

Objective : The pejorative role of pregnancy on the future prognosis of HIV infection in women is contreversial and difficult to assess in the absence of comparative groups.
Methods : Between october 1985 and october 1988, we conducted a follow up of cohort of 3 groups of women. Group 1 : Pregnant women with deliveries (n = 97), group 2 : Pregnant women with induced abortion, group 3 : non Pregnant women. The three groups were studied for risk factors CDC classification status, immunological and virological parameters.
Results : A few patients were last of follow up, althrough 55 % were drug addicts. None of the patients was initially in group IV of CDC.
1° The evolution through group IV of CDC was respectively 87 → 13 in group 1, 82 → 3 in group 2, 121 → 7 in group 3.
2° Active HIV infection was defined as CD4 ∠ 150/mm^3, Ag p24 positive and antibody anti p24. The evolution through "active state" was respectively with more than 18 months of surveillance : 5 → 18 in group 1, 8 → 11 in group 2, 11 → 15 in group 3.
3° Identical results were observed with the primipar a women.
Conclusion : These preliminary results suggest that pregnancy with delivery induces an adverse effect on clinical and immunological parameters in HIV women.

M.B.P.35 Quantification of glomerular and tubular marker proteins in urine of hemophiliacs with positiv HIV antibody test

D. Schmidt, H. Pohlmann°, W. Hofmann, W. Schramm°, J. Eisler°, W. G. Guder°
Inst. Clin. Chem. StKd.-Krh. München-Bogenhausen and °Med. Klin. Innenstadt Ludwig-Maximilians Univ., Munich, FEDERAL REPUBLIC OF GERMANY

Renal complications in acquired immuno deficiency syndrome (AIDS) are a common observation. It is however not clear whether the so called AIDS-related nephropathy is a primary event of viral infection or secondary due to opportunistic infections or other accompanying complications (malignancies, heroin use). We investigated 56 patients with Hemophilia A 42 were HIV antibody positive (Group B) between 2 and 7 years (average 4.75 years). According to the CDC classifications system 20, 16, and 6 patients belonged to group II, III and IV respectivel To detect glomerular and tubular renal dysfunction we applied a new automated program of 5 urinary parameters (total protein, IgG, albumin, alpha-1-microglobuline and N-acetyl-β-D-glucosaminidase (NAG) as well as creatini and alpha-1-microglobuline in serum. All urinary parameters were related to creatinine to correct for different excretion rates.
Serumcreatinine and alpha-1-microglobuline were normal in all patients of both groups. All urines but 2 were negative by test strip for albumin. These 2 patients (Group B) had manifest proteinuria of complete tubulo-glomerular type. Of the remaining 40 Group B patients 8 had slight elevations of urinary IgG excretion, of whic 3 had a simultaneous increase in urinary albumin and only one had signs of tubular proteinuria. The dysproteinurias were evenly distributed over Group II and III (CDC) patients. 4 of the Group IV patients were also normal A statistically significant difference between Group A and B was found only for urinary IgG.
Our results show that hemophilic patients without and years after infection with the HIV virus have no evidence of glomerular and tubular dysfunction. The assumption that AIDS-related nephropathy is not caused by direct viral invasion of the kidney is supported by our observation. Elevated levels for uinary IgG in absence of elevated urinary albumin are more likely of postrenal rather than of glomerular origin due to other illnesses such as opportunistic infections.

M.B.P.36 ISOLATION OF A BACTERIUM FROM EPITHELIOID ANGIOMATOSIS.

Cockerell, Clay J.*; Zucker-Franklin, D.**; Tierno, P.M.**; and Friedman-Kien, A.E.**
*U. of Texas Health Sciences Center, Dallas, TX; and **New York University Medical Center, New York, NY, USA.

Objective. To isolate a bacterial organism from lesions of Epithelioid Angiomatosis, a widespread eruption of reddish, vascular papules we have recently described, seen in patients with AIDS or AIDS-Related Complex. A bacterial etiology has been postulated for this condition, and organisms have been demonstrated within skin lesions using special silver stains as well as by electronmicroscopy. This bacterium closely resembles and may represent the same organism which causes cat scratch disease.
Methods. Lesions from a patient with epithelioid angiomatosis were placed in brain-heart infusion supplemented broth at room temperature and from this a pleomorphic gram negative short bacillus measuring approximately 0.3µl in diameter to 1-2µl in length was isolated. By light microscopy, the bacteria were noted to cluster in groups of variable sizes and bacilli formed buds at the ends of individual cells.
Results. Electronmicroscopy of a cutaneous lesion demonstrated a population of bacilli located extracellularly between collagen bundles of the dermis. The organisms (0.5µl to 1µl) possessed a trilaminar membrane but no well-defined cell wall. There was marked pleomorphism and buds of various sizes were noteworthy.
Conclusion. This organism is likely to be the causative agent in this cutaneous manifestation associated with AIDS and HIV infection.

M.B.P.37

AZT's EFFECT ON RESPONSES TO PNEUMOCOCCAL VACCINE (PV).

Glaser, Jordan B*; Volpe, S.* and Schiffman, G.**.
*The Staten Island Hospital, SI, NY, **SUNY-Health Science Center, Brooklyn, NY, USA.

Objective: To evaluate AZT's effect on PV-induced antibody (Ab) responses since they are suboptimal for untreated AIDS patients (pts).
Methods: PV was administered to 19 subjects receiving AZT and 4 AIDS pts not treated with AZT. Ab titers to 12 P capsular antigens were measured by RIA for all pts pre- and 30 days post-PV and for certain AZT pts prior to AZT institution (10 pts) and/or 8 mos post-PV (13 pts).
Results: Aggregate Geometric Mean Ab Titer ± Dev. (ng AbN/ml)

Group	Pre-PV	30-day Post-PV	8 month Post-PV
No AZT	700.7 ± 2.0	763.8 ± 2.1	---
AZT	564.1 ± 2.0	942.9 ± 2.3	594.9 ± 4.7

Pre-AZT Ab levels (477.2±1.8) were similar to pre-PV levels (533.3±3.5) for 10 pts treated with AZT for mean 13 wks (range 9-21) pre-PV. "Protective" levels (post/pre ratio ≥ 1.4 & Ab titer >300 ng AbN/ml) were achieved for AZT (ratio 1.7) but not the non-AZT group 30 days post-PV. For AZT pts, 30-day post-PV type specific levels were "protective" for types 4,6A,7F,8,9N,14,18C, 19F,23F but not 1,3 or 12F. "Protective" aggregate levels were present at 8 mos for 6/13 pts alive (765.8±2.8; ratio 1.5) but not for the 7 pts dead (564.3±4.9; ratio 1.0) 14 mos post-PV.
Conclusions: AZT has no effect on Ab levels prior to vaccination. Vaccinated AIDS/ARC pts receiving AZT develop "protective" levels at 30 days, whereas, those not receiving AZT do not. Patients with waning of aggregate Ab levels at 8 mos have poor short term survival.

M.B.P.38

Growth of the Cat Scratch Disease Bacillus from Skin lesions and blood in two HIV positive men.

Ma P. Nord J. and Oliver J. St. Vincent's Hospital & Med Ctr of New York, U.S.A.

We report 2 patients who presented with fever and disseminated pustular and nodular skin lesions which on biopsy revealed epithelioid angiomatosis. One patient also had lymphadenopathy. Both biopsies showed pleomorphic organisms in the Warthin-Starry silver stain and electron microscopy of one biopsy was positive for coccobacillary forms consistent with the Cat Scratch Disease bacillus (CSB).

Histopathologically, the lesions presented a pattern which resembled that of a pyogenic granuloma with anastomosing vessels and an acute inflammatory infiltrate. On occasion, a dermal vascular component was also noted. No evidence of Kaposi's sarcoma was noted.
Culture of the skin lesions in both patients yielded gram negative pleomorphic bacilli in biphasic Brain Heart Infusion medium grown at 30ºC in 2 weeks. Blood culture from one patient yielded identical appearing organisms in Bactec blood culture 6A aerobic vial incubated at 30ºC which slowly reached a positive growth value of 30. The anaerobic vial showed a negative reading after 4 months. Erythromycin therapy led to improvement in one patient and clearing of all lesions in the second patient.

We recommend that the microbiological work-up of HIV positive patients with disseminated skin lesions should include special smears and cultures for the CSD bacillus.

M.B.P.39

EMPIRIC ANTIBIOTHERAPY OF FEBRILE EPISODES IN HIV CARRIERS

Michael Finaud*, J. Rossi*, J.C. Mayordome*and P. Casanova.
*Infections unit MARSEILLE FRANCE.

Objective : to test the efficacy of an Empiric Antibiotherapy in HIV1 infected to cure bacterial infectious of febrile episodes before an opportunistic infection is documented.
Methods : in a serial of 40 febrile episodes (temperature ≥ 38°5 more of 48 hours) whitout any clinical sign of opportunistic infection and before bacteriological results is obtained we test 2 arms of therapy in a randomized study : Arm A : PEFLOXAXIN 400 mg IV/12h plus TOBRAMYCIN 3,5 mg/kg/12h IV. Arm B : CEFALOTIN 1g/IV/12 h plus TOBRAMYCIN 3,5mg/kg/12h. If an opportunistic infection occurs : the study is stopped. All patients were infected with HIV 1, group III and IV of CDC'S.
Results : At the moment, 36 episodes evaluable ; in 28 cases fever was sensible to antibiotics and a bacterial infection was documented in 9 cases bacterial infection was highly probable in 12 cases ; opportunistic fungal systemic infection was associated in 8 cases ;AMPHOTERICIN B is added to antibiotics to obtain apyrexia.Failure was observed in 8 cases ; in those cases an opportunistic infection was documented several days after therapy. No difference is observed between arm A ou B.
Conclusion : an empiric antibiotic combination therapy seems to be effective to treat febrile episodes in HIV carriers ; in most of our documented bacterial infections, such combination as PEFLOXAXINE or CEFALOTIN plus TOBRAMYCIN is in vitro and in vivo sensible. This empiric strategy can prevent the dissemination of co-infection with bacterial staine frequently isolated in immunocomprimised hosts especially in intra veinous drug addicts (32/40 in this serial).

M.B.P.40

COMPARATIVE STUDY OF CLINICAL AND PATHOLOGICAL DIAGNOSIS IN 35 PATIENTS WITH AIDS.

Del Bianco,R.;Sullemmann,J.;Araujo,M.F.;Prado,P.; Carnaúba,D.; Mecelis,R.L.; et al.
Hospital Emilio Ribas;
Centro de Referência e Treinamento-Aids,Sao Paulo,Brazil.

Objective.Analysis of the clinical and laboratory diagnosis comparing to the pathological findings.
Methods.35 patients were studied:25(71,4%)homosexual men, 4 .bisexual,1haemophiliac,1 heterosexual,2 drug addicts,1 recipient of blood transfusion and 1 child of antibody positive mother (2,8%).All the patients had evidences of imunological deficiencies and sorologic tests positives (Elisa and Western Blott).
Results.The average days of permanence of these patients in the hospital were 39,3 days.Many opportunistics infetion were recognized clinically:M.Tuberculosis in 12 patients(34,2%),P.Carinii in 9(25,7%),T.gondii in 4(11,4%),Herpes simplex in 3(8,5%) and C.neoformans in 3(8,5%).In the pathological exams the M.Tuberculosis were found in 10 patients(28,5%),M.avium in 3(8,5%),T.gondii in 8(22,8%),C.neoformans in 3(8,5%) and CMV in 11(31,4%).
Conclusion.M.Tuberculosis is often found in these patients,determined by clinical laboratory and pathological findings.

M.B.P.41

APPORT DE LA TOMODENSITOMETRIE AU DIAGNOSTIC DES COMPLICATIONS PULMONAIRES DU SIDA DE L'ADULTE

Trotot P.M.*, Sandoz-Trenca C.*, Marichez M.**, Lavillain R.*
*Institut Pasteur; **Hôpital Saint-Joseph, Paris, France.

Objectifs: évaluer l'apport de la Tomodensitométrie (TDM) au diagnostic précoce et au suivi des atteintes pulmonaires au cours du SIDA de l'adulte.
Méthode: reprise des dossiers des 300 derniers patients hospitalisés. Parmi ceux qui présentaient des complications pulmonaires, détermination de l'apport de la TDM.
Résultats: dans les atteintes en foyer, la TDM n'est le plus souvent d'aucun apport supplémentaire par rapport au simple cliché pulmonaire.
Par contre dans les atteintes diffuses elle peut être déterminante en reconnaissant l'infiltrat alvéolaire sec de la pneumocystose et son évolution éventuelle vers l'emphysème centro-lobulaire parfois compliqué de pneumothorax, l'alvéolite oedémateuse allergique, la miliaire tuberculeuse interstitielle, ou les nodules disséminés du sarcome de kaposi.
Conclusion: le caractère atraumatique et la précision anatomique de la TDM millimétrique sans injection en font, avant le lavage alvéolaire, ou si celui-ci n'est pas possible, un élément essentiel du diagnostic et du suivi thérapeutique.

M.B.P.42

EVOLUTION OF LUNG HIV-SPECIFIC CTL ACTIVITY AND CLINICAL CORRELATIONS.

GUILLON JM*,JOLY P*,AUTRAN B*,PLATA F°,DEBRE P*, MAYAUD C' et al. *Lab. Immuno., Hôp. Pitié-salpêtrière; °Lab. Immuno. Biol. Rétrovirus,I. Pasteur and 'Dpt. Pneumo., Hôp. Tenon,Paris FRANCE

OBJECTIVE : We previously described lung HIV-specific class-I-restricted CTL, essentially in patients at early stages of HIV disease. In this study,1) we prospectively evaluate the level of anti-HIV CTL activity during the course of the disease; 2) we analyse both its consequences on lung function and its clinical relevance.
METHODS : A cohort of 41 HIV-positive patients was evaluated with long-term follow-up studies for 17 of them. The specific cytolytic function of lung lymphocytes was tested on autologous alveolar macrophages and cell lines expressing HIV proteins. The lung function was simultaneously evaluated.
RESULTS : The intensity of alveolar CTL lysis specific for HIV was markedly reduced in ARC and AIDS patients when compared with healthy seropositive carriers and patients with the lymphadenopathy syndrome ($p<0.01$), although a weak activity could still be detected in a few AIDS patients. In sequentially studied patients, we observed a progressive decline in CTL activity as the clinical status deteriorated.In another hand, in those patients with significant CTL activity, some respiratory disorders could be defined including minor respiratory symptoms, interstitial pneumonitis and abnormalities of gas exchanges.An improvement of lung function was paradoxically observed in some patients several months before the onset of an opportunistic lung infection , as a parallel with the disappearence of CTL activity.
CONCLUSIONS :Our data strongly suggest a protective role for HIV-specific CTL although they can be deleterious to the function of the lungs.

M.B.P.43

THE VALUE OF GALLIUM-67 SCAN IN THE DIAGNOSIS OF LYMPHADENOPATHY IN SYMPTOMATIC HIV-INFECTED PATIENTS.

Podzamczer,Daniel; Ricart, I.; Bolao,F.; Bonin,D.; Romagosa, V.; Gudiol,F., Hospital de Bellvitge, University of Barcelona,Barcelona,Spain.

Objective. To study the utility of chest gallium-67 citrate scan (GCS) in the differential diagnosis of enlarged lymph nodes in HIV-infected pts with constitutional symptoms.

Patients and methods. Nineteen HIV-positive pts (15 drug addicts and 4 homosexuals) with fever and/or weight loss and localized or generalized lymphadenopathy were evaluated with chest GCS. A positive GCS was considered when an increased focal uptake in cervical, axillary and/or supraclavicular nodal areas was observed. Subsequently, a lymph node biopsy was done in all pts.

Results. In 9 pts GCS disclosed an increased uptake in one or more nodal areas. One of them had follicular hyperplasia while in the other 8,biopsies showed ganglionar mycobacteriosis (7 M. tuberculosis and 1 non-specified atipical mycobacteria). Five of them had also mediastinal uptake. Ten pts had negative GCS. Biopsies showed follicular hyperplasia in 9 and Kaposi's sarcoma in the remainder.

Conclusion. This preliminary study suggests that in HIV-infected pts with constitutional symptoms and lymphadenopathy, a negative GCS probably represents follicular hyperplasia. In this setting, a surgical approach may be avoided unless Kaposi's sarcoma is suspected. Conversely, a positive GCS strongly suggests a mycobacterial infection.

M.B.P.44

LYMPHADENOPATHY AND HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION IN SÃO PAULO, BRAZIL.

[illegible]*; Nascimento, M.F.A.*; Batista, L.*; Albano, A.*.
* Hospital Emílio Ribas, São Paulo, SP, Brasil.

Objective: To analyse the lymph node histopathologic changes in patients with HIV infection, and determine clinical and epidemiological characteristics of these patients in São Paulo.

Methods: The study group included all 70 patients with HIV infection (proved by serological and clinical data) in whom lymph node biopsy was performed at our hospital between 1985 and mid 1988. Epidemiological and histological findings were determined in order to group the patients. Within each group we determined the frequency of sex, age, risk factors for HIV infection and microbiological and clinical diagnosis.

Results: Sixty patients were male. The most important risk factors for HIV infection were male homosexual contact (40 patients) and intravenous drug abuse (20 patients). The histopathologic findings are showed on the following table.

Diagnosis	Number of Cases	Percentage
Mycobacterial infection	34	48.5
Follicular hyperplasia	21	30.0
Mycosis	7	10.0
Kaposi sarcoma**	4	5.7
Follicular atrophy	4	5.7
Lymphoma**	1	1.4

** In one case the diagnosis was Kaposi sarcoma and lymphoma

M. tuberculosis was identified in 24 (70.5%) of 34 cases of mycobacterial infection. Within the pattern of follicular hyperplasia, 11 patients (52.4%) were classified in group 3 (CDC classification for HIV infection), 8 (38.1%) in group 4,and 2 (9.5%) in group 2.

All patients that had the lymph node histological pattern of follicular atrophy were classified in group 4.

Fungi infections were represented by *Histoplasma capsulatum* (4 cases), *Cryptococcus neoformans* (2 cases) and *Paracoccidioides brasiliensis* (1 case).

The commonest histopathologic finding among homosexuals was mycobacterial infection (57.5%), whereas follicular hyperplasia represented 52.3% of intravenous drug abusers cases.

Conclusion: Tuberculosis is the most frequent lymph node infection in patients with HIV infection in São Paulo, besides occuring in early stages of HIV infection. Follicular hyperplasia is frequent in AIDS too. Further investigations must be done to compare lymph node histopathologic findings among homosexuals and intravenous drug abusers.

M.B.P.45

SERONEGATIVE DISSEMINATED COCCIDIOIDOMYCOSIS IN PATIENTS WITH HIV INFECTION.

Antoniskis Diana, Rarick MU, Akil B, Larsen RA, Leedom JM. Los Angeles County-University of Southern California Medical Center, Los Angeles, California, USA.

Objective: Serologic testing for compliment fixing (CF) antibodies to Coccidioides immitis is commonly employed to assist in the diagnosis and management of patients infected with this fungus. CF response in patients with concurrent HIV infection and disease due to disseminated C. immitis was examined in order to determine antibody response.

Methods: After noting a case of disseminated C. immitis with negative CF antibodies, we reviewed our experience in patients with both HIV and disseminated C. immitis infection. All mycologically or histologically proven cases of disseminated C. immitis infection since 1984 were reviewed for risk factors associated with HIV infection or for serologic evidence of HIV infection.

Results: Disseminated C. immitis and HIV infection were found in 11 patients; 8 had CF antibody titers performed. CF antibodies were detected in 6 of 8 serum samples (in a range of 1:16 to 1:256). Six patients also had cerebrospinal fluid CF antibody performed, 4 were positive (range 1:1 to 1:8). Two patients had persistently negative serum CF antibody tests.

Conclusion: Serologic testing for C. immitis CF antibodies may be negative in 25% of patients with disseminated disease when there is concurrent HIV infection. Histopathology and culture remain the most reliable method for the diagnosis of disseminated coccidioidomycosis.

M.B.P.46

COCCIDIOIDOMYCOSIS AMONG PATIENTS INFECTED WITH HIV. A PROSPECTIVE EPIDEMIOLOGIC STUDY.

Ampel, Neil M; Dols, CL; Galgiani, JN.
Tucson Veterans Administration Medical Center, University of Arizona, Tucson, Arizona, U.S.A.

Objective. To prospectively follow HIV-infected individuals for the development of coccidioidomycosis in an area endemic for Coccidioides immitis in order to determine risk factors associated with acquisition of this fungal infection.

Methods. Patients infected with HIV and living in Tucson, Az have been followed since May 1988. Clinical evaluation and laboratory tests, including T4 lymphocyte count, coccidioidal skin-tests and lymphocyte transformation assays were performed on entry and every 4 months thereafter.

Results. A total of 58 individuals have been entered. 57 are men; 47 are white; mean age = 37 yr; mean T4 = 438. Since the study began, 3 patients have developed active coccidioidomycosis. Using clinical, epidemiological and immunological data, analysis of the 55 individuals without active coccidioidomycosis revealed that 8 have clear evidence of prior coccidioidal infection, 14 have no evidence of prior coccidioidomycosis, and 8 are too immunologically compromised to make that determination. For the remaining 25, data is incomplete. Hence, 11 of 33 individuals so far evaluated either have active coccidioidomycosis or evidence of prior infection.

Conclusion. These preliminary data from a prospective study indicate that coccidioidomycosis represents a major infection among HIV-infected individuals living in an area endemic for C. immitis. Further study will be required to determine whether active coccidioidomycosis in this cohort is due principally to reactivation or acute aquisition of infection.

M.B.P.47

SUCCESSFUL TREATMENT OF ACYCLOVIR-RESISTANT HERPES SIMPLEX VIRUS II WITH FOSCARNET IN A PERSON WITH AIDS

* [illegible]; * Muller,K.; * Blair,S.; * Kathpalia, S.; ** Muldoon, R.; *** Edgar Hill, et.al.
* Section of Retrovirology, Division of Infectious Disease, Cook County Hospital; ** Division of Virology, Department of Laboratories, Hektoen Institute. *** Burroughs-Wellcome, Co. , Chicago, IL, U.S.A.

Objective. Investigation of foscarnet as an alternate treatment of acyclovir-resistant herpes simplex virus II infection in AIDS.

Methods. A 28 y.o. black woman with HIV positivity for 2 months and 220 T4 cells presented with AIDS and severe vulvo-vaginal, perineal, and perirectal HSV II infection in November, 1988. The lesions extended from the mons veneris to the peri-anal area. There was no response to intravenous acyclovir 10 mg/kg TID and nafcillin for 14 days. The addition of zidovudine produced no additional benefit. A trial of ARA-A alone was discontinued after 5 days due to severe leukopenia and thrombocytopenia. AZT and acyclovir at 20 mg/kg/ml were resumed, with serum levels of 48 ugm/l (peak) and 22 ugm/l (trough), and no response was observed. HSV sensitivities to 3 drugs - acyclovir, ARA-A, & foscarnet - performed by automated colorimetric analysis are shown in table I:

TABLE I 10-50 ug/ml

	Acyclovir	ARA-A	Foscarnet
Patient	35.4	11.8	48.9
Controls	0.6	12.1	25.6

Foscarnet was begun at 30mg/kg q 8h; the serum creatinine was 2.0.mg/ml.

Results: Symptoms improved immediately, and there was complete healing after 3 weeks. No renal or calcium metabolism abnormalities were observed. The patient is currently stable on AZT.

Conclusions: Foscarnet is an effective alternate therapy for thymidine-kinase (TK) deficient or TK-altered acyclovir-resistant Herpes Simplex virus II in persons with AIDS. Early diagnosis by culture and sensitivity is essential. Further clinical trials of foscarnet are warranted.

M.B.P.48

FOSCARNET TREATMENT OF ACYCLOVIR (ACV)-RESISTANT HERPES SIMPLEX VIRUS (HSV) INFECTION IN 26 AIDS PATIENTS.

Sharon Safrin*, T. Assaykeen**, S. Follansbee**, J. Mills*
*San Francisco General Hospital, University of California ; **Institute for HIV Research, Davies Medical Center, CA ; and ***Astra Clinical Research Associates, Hopkinton, MA , U.S.A.

Objective: To assess the efficacy of intravenous foscarnet for treatment of acyclovir-resistant mucocutaneous HSV in patients with AIDS.

Methods: Data was obtained prospectively and retrospectively from the charts of 26 patients in the U.S. receiving compassionate usage foscarnet for ACV-resistant HSV.

Results: Twenty-six patients had 34 episodes of mucocutaneous HSV (25 perirectal, 7 orofacial, 1 genital, 1 whitlow) that progressed despite therapy with intravenous (19 patients) or high-dose oral (7 patients) ACV, vidarabine (15 patients) or ganciclovir (3 patients). All initial isolates were susceptible *in vitro* to foscarnet and resistant to ACV. Patients received foscarnet for 10-43 days (mean 18.5). Twenty-two patients responded dramatically with re-epithelialization of lesions; one patient failed to demonstrate clinical improvement. All thirteen patients who were re-cultured during therapy with foscarnet had cessation of viral shedding, one as early as day 3. In three patients, therapy was discontinued due to adverse effects (2 leukopenia, 1 azotemia), and 1 patient died of unrelated causes after 2 days of therapy. Fourteen patients had recurrence of HSV at an interval ranging from 7 days to 6 months after therapy. Eight were re-treated successfully with foscarnet, 3 with ACV, and 3 have not yet been re-treated. Eight patients have received maintenance therapy with foscarnet.

Conclusions: Foscarnet is an effective and relatively non-toxic agent for therapy of acyclovir-resistant HSV in AIDS patients. Based on the limited experience in this series of patients, vidarabine is less effective than foscarnet in treating ACV-resistant HSV infection. Recurrence of herpetic lesions is common after discontinuation of antiviral therapy.

M.B.P.49 SUCCESSFUL THERAPY OF PROGRESSIVE ACYCLOVIR-RESISTANT ORO-FACIAL HERPES SIMPLEX WITH INTRAVENOUS FOSCARNET IN AN AIDS PATIENT

Sall, Richard K., Kauffman CL, and Levy CS.
Washington Hospital Center and George Washington University Medical Center, Washington, D.C., U.S.A.

Objective. To determine the clinical efficacy of intermittently administered intravenous foscarnet in the treatment of progressive acyclovir-resistant herpes simplex virus infection.
Method. A 31-year-old homosexual white male with a history of AIDS post pneumocystis pneumonia developed a type 2 herpetic lesion on his left upper lip. The lesion resolved initially with oral acyclovir but recurred several months later and progressed to involve the majority of the patient's face despite multiple courses of oral and intravenous acyclovir. Antiviral susceptibilities were obtained for this isolate.
Results. Using a VERO tissue culture and plaque reduction assay, the virus was shown to be resistant to acyclovir in-vitro, but susceptible to vidarabine and foscarnet. Despite two weeks of intravenous vidarabine the lesion failed to respond. Therapy was changed to intravenous foscarnet (40 mg/kg every eight hours). After a three week course of treatment the lesion had completely re-epithelialized except for a residual peripheral crust. However, the lesion recurred once foscarnet was discontinued and herpes simplex was again cultured.
Conclusion. Intravenous foscarnet has efficacy in the treatment of clinically significant acyclovir-resistant herpes simplex infection, but chronic suppressive therapy may be required.

M.B.P.50 ULCERATIVE HERPES SIMPLEX (UHS) IN AIDS PATIENTS.

Carminati,Guido;Zerboni,R.;Mensi,M.;Cusini,M.;Muratori,S. and Alessi,E.
1st Clinic of Dermatology,University of Milan,Milan,Italy.

Objective. To define the diagnostic procedures, to evaluate the response to therapy and to assess the course and final outcome of 9 HIV positive patients with UHS of the anogenital area.
Methods. Tzanck's smears,histology,electron microscopy,cultures and immunocytochemical methods for HSV antigen were used to confirm the clinical diagnosis. ACV treatment was done. The patients were followed for herpetic recurrences,other AIDS manifestations and immunological parameters up to 20 months.
Results. At enrolment, Tzanck's smears were found positive in 8 patients,HSV type 2 was demonstrated in 7, a profound immunosuppression and concurrent opportunistic infections were present in 7. Acyclovir healed the lesions in all patients, but one or more recurrences were observed in 6. The new herpetic episodes were ACV sensitive in 5 patients, while an in vivo and in vitro resistant HSV type 2 strain was isolated in one patient. This patient was successfully treated by Foscarnet. During the follow up, 7 patients developed other major AIDS manifestations and 3 patients died.
Conclusion. Several methods are necessary to diagnose UHS. ACV therapy is usually effective. The survival time of patients with UHS seems longer than that of patients with other major opportunistic infections.

M.B.P.51 SUCCESSFUL TREATMENT OF SEVERE, ACYCLOVIR-RESISTANT HERPES SIMPLEX VIRUS TYPE 2 PROCTITIS IN TWO PATIENTS WITH AIDS: USE OF CONTINUOUS INFUSION ACYCLOVIR.

Engel, Jeffrey*; Englund, J.**; and Fletcher, C.***.
*East Carolina University School of Medicine, Greenville, North Carolina, USA; **Baylor College of Medicine, Houston, Texas, USA; ***University of Minnesota College of Pharmacy, Minneapolis, Minnesota, USA.

Objective. To report on the efficacy and safety of continuous infusion acyclovir (ACV) for the treatment of severe, ulcerative proctitis caused by ACV-resistant herpes simplex virus (HSV) type 2 in two patients with AIDS.
Methods. Viral cultures were obtained on cotton tipped swabs, inoculated onto tissue culture, and observed for cytopathic effect typical for HSV. HSV isolates were typed with restriction endonuclease digestion. ACV plasma levels were measured by RIA. HSV sensitivities to ACV were determined by measuring viral growth by quantitating viral DNA with an HSV specific radiolabeled probe in the presence of varying concentrations of ACV. Results are expressed as an ID$_{50}$.
Results. Both patients developed severe ulcerative proctitis from HSV type 2 with progression despite prolonged courses of oral ACV followed by 3 weeks of intravenous ACV administered at 10mg/kg every 8 hours. Both patients' isolates developed ACV resistance with ID$_{50}$ values of >20 µmol/L (normal for HSV type 2 is <2 µmol/L). Continuous infusion ACV was administered at 1.5-2.0 mg/kg/hr via Hickman catheters to maintain ACV levels in plasma between 20 and 30 µmol/L. Within a week of this therapy, the patients noted improvement in their proctalgia and by the sixth week had total healing of their lesions. Serum creatinine levels remained normal. The continuous infusion was accomplished in an outpatient setting with weekly visits and ACV and creatinine determinations.
Conclusions. Continuous infusion ACV was efficacious and safe in treating severe HSV-induced proctitis in two patients with AIDS despite the development of high level resistance to ACV, and previous failure with ACV administered in divided doses.

M.B.P.52 ACICLOVIR THERAPY OF ACUTE RETINAL NECROSIS SYNDROME (ARN) IN AIDS PATIENTS

Eva-Maria Fabricius.
Augenklinik des Krankenhauses Harlaching, Munich, FRG.

Objective. To prove whether Aciclovir long term therapy is necessary to prevent relapses of Acute Retinal Necrosis Syndrome (ARN) caused by Herpes simplex Virus (HSV) or Varicella Zoster Virus (VZV) as opportunistic ocular infection.
Methods. Retrospective report on 4 patients with ARN. 3 had got Aciclovir therapy for extraocular herpetic infections over a limited period before, one received Aciclovir initially for treatment of ARN and HSV encephalitis (1500 mg/d intravenously), followed by long term therapy (800 mg/d per os) over a 7 months follow up period.
Results. In the 3 cases with extraocular diseases ARN occurred several weeks after suspension of Aciclovir therapy causing rapid visual damage. In one case initial Aciclovir therapy provided resolving of ARN and cerebral symptoms, maintenance therapy has prevented relapses for 7 months.
Conclusion. ARN should be an indication for long term therapy with Aciclovir to prevent blindness in AIDS patients.

M.B.P.53 HIV, HUMAN PAPILLOMAVIRUS, AND CERVICAL DYSPLASIA IN NAIROBI PROSTITUTES

Kreiss, Joan*; Kiviat,N.*; Plummer,F.**; Ngugi,E.***; Waiyaki,P.+; Holmes,K.* *University of Washington, Seattle, WA; **University of Manitoba, Winnipeg, MB, Canada; ***University of Nairobi; +Kenya Medical Research Institute, Nairobi, Kenya.

To determine whether HIV infection in women is associated with an increased frequency of human papilloma virus (HPV) infection or cervical dysplasia, we studied 145 Nairobi prostitutes. Cervical samples were obtained for cytology and HPV detection by dot filter hybridisation (Virapap).
Results. The mean age of the study population was 31 years. The average number of sex partners per week was 21. 69% of women were seropositive for HIV, of whom 76% had generalised lymphadenopathy: none had overt AIDS. Thirty-two (24%) of 136 women had cervical HPV infection, including 27% of HIV positive and 19% of HIV negative women. Five (16%) HPV types were 16/18, 14 (44%) were 31/33/35, and 13 (41%) were other. No association was noted between HPV infection and age, number of sex partners, use of spermicides or hormonal contraception, or lymphadenopathy. Of 125 cervical cytologic examinations, 2 (2%) showed cervical intraepithelial neoplasia (CIN), 15 (12%) showed atypia, and 108 (86%) were normal. Only 1 (4%) of the women with HPV had CIN.
Conclusion. Prostitutes in Nairobi have a high prevalence of HPV infection but no association between HIV and HPV was observed. Cervical dysplasia was present in only 2% of women. Prospective evaluation of this cohort will help to determine whether the natural history of HPV infection and the risk of HPV-associated cervical dysplasia is affected by concurrent HIV infection.

M.B.P.54 PREVALENCE AND RISK FACTORS FOR HIV-1 INFECTION IN PATIENTS WITH ACUTE PELVIC INFLAMMATORY DISEASE (PID)

Sharon Safrin, BJ Dattel, LB Hauer, R Edison, W Crombleholme, RL Sweet, et al; University of California, San Francisco, SF General Hospital, USA.

Objective: To examine temporal trends and risk factors for HIV-1 seropositivity in a population of women admitted with the diagnosis of acute PID.
Methods: This is an extension of our continuing retrospective analysis of stored sera from women admitted to an urban county hospital with acute PID. Sera from the years 1985-1988 were anonymously tested for antibody to HIV-1; demographic data and 15 separate risk factors were extracted by blinded chart review. In January 1989, we initiated a prospective study utilizing anonymous seroprevalence testing for HIV-1 and coded risk factor questionnaires; we will report on this data as well.
Results:

Year	#HIV seropositive/# tested	%HIV seropositive
1985	0/16	0
1986	2/103	1.9
1987	4/95	4.2
1988	8/119	6.7

Of the risk factors, intravenous drug use correlated significantly with HIV-1 seropositivity (OR = 23.2, 95% CI = 5.0 - 106.9). Among other risk factors, type of drug used, number of sexual partners, and previous history of sexually transmitted diseases did not correlate.
Conclusions: Overall seroprevalence of HIV-1 was 4.2% (95% CI = 2.4% - 6.4%) in women admitted for acute PID in 1985-1988, and increased from 0 to 6.7% during this time period. This is contrasted with a seroprevalence of 0.9% in 1148 obstetric patients at San Francisco General Hospital; risk factor analysis will attempt to discern differential risk factors in these populations.

M.B.P.55

DIAGNOSTIC ET TRAITEMENT DES LESIONS CERVICO-VAGINALES ET VULVAIRES A PAPILLOMAVIRUS CHEZ LES FEMMES SERO-POSITIVES POUR LE VIRUS VIH.

Caubel, Patrick ; Foulques, H.; Blondon, J.; Lefranc, J.P.
Hôpital de la Salpêtriere, Paris, France.

Objectif. Dégager, à partir de l'observation de 20 patientes (âge moyen = 27,4 ans) séro-positives pour le virus VIH (75,0 % de contamination par toxicomanie intra-veineuse), les principaux caractères épidémiologiques, diagnostiques et pronostiques des lésions cervico-vaginales et vulvaires dues à une infection à papillomavirus (HPV).
Méthodes. Les lésions dépistées par l'examen colposcopique ou cytologique et confirmées histologiquement fûrent ensuite détruites par vaporisation au laser CO_2.
Résultats. 58,6 % des frottis cervico-vaginaux révélaient une infection à HPV, et chez 6 patientes l'histologie cervicale a retrouvé des anomalies allant de la dysplasie légère (2 cas) ou modérée (3 cas) au carcinome invasif (1 cas). 30 % des patientes présentaient des lésions vulvaires à HPV associées. Après destruction au laser (13 patientes) le taux de récidives est de 23 % (recul moyen de 11,2 mois).
Conclusion. La fréquence élevée des lésions génitales à papillomavirus chez les patientes infectées par le VIH rend nécessaire leur dépistage colposcopique et cytologique afin d'assurer leur éradication avant ou au début de leur évolution vers la dysplasie.

M.B.P.56

Human immunodeficiency virus and Human papilloma virus in the cervical intraepithelial neoplasia (CIN) in development of past intravenous drug abusers (PIVDA)women.

Maria Luisa Muggiasca,E.Conti*,L.Ravasi,D.Imperiale,A.Agarossi,M.Conti
VII and IV* Department of Obstetrics and Gynecology, University of Milan,Italy

Objective To investigate a possible association between HIV and HPV infections in the development of CIN.
Methods 209 PIVDA (101 HIV pos,mean age 25.2 yrs,S.D.±3.9;108 HIV-,mean Age 25.8 yrs.,S.D.±4.6)women,residenting in a rehabilitation community where investigated by cervical citology,colposcopy and by colposcopically directed biopsy.Statistical significance was evaluated by chi square analysis and by Fischer's exact test.
Results CIN was found in 18 HIV pos (17.8%), and in 7 HIV neg(6.5%).
CIN + HPV (Pap smear + histological examination) were found in 13 HIV pos. (12.9%) and in 4 HIV neg (3.7%).
HPV (Pap smear + histological examination) was found in 25 HIV pos(24.7%)and in 7 HIV neg (6.5%).
CIN is more frequently observed in HIV pos than HIV- women (P<.05) and control group (1534 university students,CIN 1.1%,*P <.0001). Association between HPV and CIN is significantly greater in HIV pos.(P<.05). Citological and histological evidence of HPV infection are more frequent in HIV pos (P <.01).

M.B.P.57

GENITAL ULCERS (GU) AND HIV INFECTION IN AN URBAN SEXUALLY TRANSMITTED DISEASE (STD) CLINIC

Chirgwin,Keith; Dillon,S; DeHovitz,J; Landesman,SH; McCormack,W. SUNY Health Science Center at Brooklyn, New York.

Objective: To investigate the association of genital ulcers (GU) and HIV infection in persons attending an STD clinic in Brooklyn.
Methods: Beginning 10/88, our STD clinic pts were routinely offered HIV testing. HIV risk factors were assessed by interview at the time of testing. Clinic records were available for 73 pts who underwent HIV testing and were retrospectively reviewed to determine STD diagnoses.
Results: 16/73 (22%) of STD clinic pts tested were HIV+. GU were present in 8/16 (50%) HIV+ pts compared with 12/57 (21%) HIV- pts (OR=3.75, p<.03). This trend increased when those with admitted HIV risk factors (N=5) (IVDU, homosexual, sexual partner with AIDS) were excluded (OR=5.6, p<.02). 7/8 HIV+ pts with GU were women and 5/7 of these women had no admitted HIV risk factors. The etiologies of GU in HIV+ pts were: 3 herpes simplex, 1 syphilis; the remaining 4 were not diagnosed definitively. Only one HIV+ pt admitted a history of previous GU. 5/16 (31%) HIV+ pts had >1 concurrent STD's diagnosed at presentation compared with 7/57 (12%) HIV- pts (NS).
Conclusion: We have noted an increasing incidence of GU disease in our STD clinic during the last 2 years. These data suggest that GU may be associated with HIV infection. As these pts were HIV seropositive at presentation, it is likely that acquisition of HIV infection either antedated or was coincident with their GU disease. The former possibility suggests an increased risk of GU disease in persons already HIV+, the latter suggests an increased rate of HIV transmission from sexual partners with GU disease.

M.B.P.58

THE RISK OF PROGRESSION OF CERVICAL DYSPLASIA IN WOMEN WITH HIV

Bradbeer C S, Heyderman E.
St.Thomas' Hospital, London, UK.

Objective. To assess the prevalence and the risk of progression of cervical dysplasia (CIN) in women with HIV.

Methods. Ten unselected women with HIV were prospectively investigated for CIN over a mean of 26 months (range 50-6).

Results. Seven have shown evidence of progression or development of CIN over the study period, no spontaneous regression was noted. Of the five who required ablative therapy, three developed recurrence of CIN after treatment. A high incidence of infection with the genital wart virus was also noted. Results for a larger number of subjects will be presented.

Conclusion. These results have implications for the provision of colposcopic services and treatment facilities as part of the management of HIV in women.

M.B.P.59

CERVICAL INTRAEPITHELIAL NEOPLASIA IN HIV INFECTED WOMEN

Sojo, Diana; Fresneda, A; Babín, F; Lazaro, A. and Abad S.
C.P.S. Centro. Madrid Council ,Madrid, Spain

Objective: We have previously described a high incidence of genital infection, cervical intraepithelial neoplasia (CIN) and in situ carcinoma of the cervix in HIV infected women. The aim of this paper is to compare the incidence of genital infection and CIN in three different groups, to clarify the relationship between HIV infection and CIN.
Methods: Three groups were compared: Group I, HIV infected women (IVDU and women infected by heterosexual transmission); Group II, control group (seronegative women with similar characteristics to group I) and Group III, prostitutes (prostitutes who were not IVDU and were seronegative).
Vaginal smear, colposcopy and microbiologial study were done in all the cases. In cases of abnormal smear or colposcopy, cervical biopsy was done.
Results: Five out of ten women in group I, one out of ten women in group II and two of 23 women in group III were found to have a CIN.

	I HIV (N=10)	II CONTROL (N = 10)	III PROSTITUTES(N=23)
CIN	5	1	2
Normal findings	5	9	21

Conclusions: No statistical differences $\bar{X}^2 = 2.14$ p 0.5) could be demonstrated between the HIV infected group and the control group. Significant differences between group I and group III were found ($\bar{X}^2 = 4.85$ P 0.05).
No differences were found in the infection rate of the three groups.
More cases and controls are now being enrolled, to clarify the lack of differences in these groups.

M.B.P.60

HIGH RATES OF CERVICAL DYSPLASIAS, CERVICAL INTRAEPITHELIAL NEOPLASIAS (CIN) AND HUMAN PAPILLOMA VIRUS INFECTION IN HIV INFECTED FEMALE PATIENTS

K. F. Hiller, R. Lutz, S. Baur, M. Stauber, University of Munich, I. Women's Hospital, Munich, Federal Republic of Germany.

Objective. To show the important role HIV infection plays in the development of dysplasias of the cervix uteri, cervical intraepithelial neoplasias (CIN), and the close relation to high rates of human papilloma virus infections observed in HIV-infected female patients.
Methods. 58 female patients were examined in regard to their immunologic status. Lymphocyte stimulation tests were performed, cytology of the cervix uteri, colposcopy, human papilloma virus DNA-hybridization by Southern Blot and Viratype testing (GIBCO Ltd.) and "open reading frame" protein detection tests were performed. In some cases histological evaluations of CINs are available.
Results. More than 15% of female patients in an age group of 20-30 yrs. show cytological signs of cervical dysplasia, approx. 8% show cervical intraepithelial neoplasias (CIN). In more than one-third of all patients we found clinical aspects, cytology or laboratory testing positive for human papilloma virus infection of various types. However, in two-thirds of patients with signs of dysplasia we found evidence for the presence of human papilloma virus infection. Percentages are even higher in patients during pregnancy (approx. 25% of patients with dysplasia). First results of "open reading frame" protein testing will be presented.
Conclusion. The synergism of HIV infection, subsequent immunosuppression and human papilloma virus infection lead to high rates of dysplasias and cervical intraepithelial neoplasias particularly in pregnancy.

M.B.P.61 INFECTION IN HIV-SEROPOSITIVE INDIVIDUALS WITH THE EBNA 2B EPSTEIN-BARR VIRUS SUBTYPE : CORRELATION WITH T4 LYMPHOCYTE NUMBERS

Buisson M.*; Eme D.**; Genoulaz O.*; Beldjord K.**; Andrieu J.M.**; Seigneurin Jean-Marie* et al.
*Virology Laboratory, Centre Hospitalier Universitaire, Grenoble;
**Laennec HIV Study Group, Hôpital Laennec, Paris, France.

Objective. EBV is associated with B cell lymphomas in HIV-infected individuals.

It is now a well established fact that, in the general population, 2 subtypes of EBV exist, referred to as EBNA 2A and EBNA 2B. The aim of this study was to determine the prevalence of infection by the rarer subtype, EBNA 2B, in HIV-positive subjects, as well as the intensity of the antibody response, according to the number of circulating T4 lymphocytes.

Methods. EBNA 2B gene was transfected in Rat 1 epithelial cells. Test sera were titrated by anticomplement immunofluorescence on monolayers of mock-transfected Rat 1 cells (R1), R1-EBNA 1, R1-EBNA 2A, and R1-EBNA 2B transfected cells. A total of 209 HIV-seropositive caucasian individuals were studied, including 107 subjects with more than 600 T4 cells/mm³ and 102 patients with less than 300.

Results. Data of prevalence and Geometric Mean Titers are summarized in the following table :

	VCA	EA	EBNA Raji	EBNA 1	EBNA 2A	EBNA 2B	
> 600 T4	100	65	99	91	82	83	prevalence
	533	41	67	77	26	25	GMT
< 300 T4	100	71	96	91	74	71	prevalence
	780	46	41	42	26	36	GMT

Conclusion. Our results suggest that 1) prevalence of, and response to, EBNA 2B subtype of EBV increases as the number of T4 cells falls, as opposed to those with EBNA 1, and 2) dual infections with both EBNA 2A and EBNA 2B subtypes might exist.

M.B.P.62 ASSOCIATION OF EPSTEIN-BARR VIRUS IN EPITHELIOID ANGIOMATOSIS OF AIDS PATIENTS

Jeannette Guarner*; Unger E.R.*
*Emory University, Atlanta, Georgia.

Objective. Epithelioid hemangioma-like vascular proliferations, recently described in AIDS patients, have been associated with bacilli similar to those found in cat-scratch disease. Since other vascular lesions present in AIDS patients, in particular Kaposi's sarcoma, have been associated with CMV, we investigated the possibility of viral associations with epithelioid angiomatosis.

Method. In-situ hybridization was performed on formalin fixed, paraffin embedded tissue from 2 cases using cloned biotinylated probes for CMV, herpes simplex (HSV), HIV and EBV.

Results. None of the 2 patients had evidence of opportunistic infection at the time the biopsy was obtained and the lesions regressed spontaneously. Hybridizations with CMV, HSV and HIV were negative, those for EBV were positive in both lesions. Hybridization signal for EBV was present in the nuclei of endothelial cells and in occasional histiocytes. Bacilli were demonstrated within only one of the lesions by silver stain.

Conclusions. This is the first report of EBV associated with this entity and the first time that EBV viral genome has been seen in endothelial cells. Our data suggest that EBV may be involved in the pathogenesis of these lesions but further studies are necessary.

M.B.P.63 EFFECTS OF rhG-CSF ON SECONDARY INFECTIONS IN AIDS

Kimura, Satoshi; Mohri, H.; Sugiyama, H.; Nakagawa, A.; Hitamura, K.; Shimada, K. et al.
The Institute of Medical Science, The University of Tokyo, Tokyo, Japan.

Objective. The effects of recombinant human granulocyte-colony stimulating factor (rhG-CSF) on secondary infections in AIDS patients were evaluated. Patients and Methods. Four consecutive AIDS patients (hemophiliacs) with various infections and leukocytopenia were treated with intravenous rhG-CSF. Patients' profiles are summarized in Table 1. The rhG-CSF was donated by KIRIN Brewery Co., Ltd. (Tokyo, Japan). Results. In case 1, 2, and 4, the numbers of WBC increased three to seven folds, and current infections were controlled by the administration of 0.1 mg/m² rhG-CSF. In case 3, however, rhG-CSF (0.1 ~ 0.2 mg/m²) showed only a little effect. This may be due to simultaneous administration of acyclovir and ara-A. No adverse effect was observed in any of these patients. The numbers of CD4⁺ cells and the levels of p24 antigen did not change during the course of the treatment.

Table 1. Background of Patients in This Study

Case	Age	Sex	Indicator disease	Current infection	Pathogens
1	33	M	Cryp.meningitis(CM)	recurrence of CM	C.neoformans
2	30	M	PC pneumonia	TEN, septisemia	St.epider., Klebsiella
3	41	M	Candida esophagitis	HZ, Mycobac.infec.	VZV, M.avium
4	21	M	PC pneumonia	abscess	St.aureus

Conclusion. In AIDS patients, rhG-CSF was very effective in the treatment of bacterial and fungal infections unless other agents suppressing the bone marrow are not used simultaneously with it.

M.B.P.64 PREVALENCE AND CLINICAL SIGNIFICANCE OF COOMB'S TEST AND COLD AGGLUTININS IN AIDS-PATIENTS

Bogner JR, Gathof B*, Heinrich B, Matuschke A, Bäcker U*, Goebel F-D: Universität München, FRG, Med Poliklinik,
* Transfusion Service of the Red Cross, München, FRG.

OBJECTIVE: To determine the prevalence and pathogenetic/ diagnostic relevance of positive direct antiglobulin tests (DAT) in AIDS patients (PTS).

METHOD: 34 (23%) out of 145 consecutive AIDS PTS (CDC criteria) attending our clinic presented with anemia requiring transfusion. Antibody screening was performed including C3,C3d,C4, antiI/JK/Le^{a}, IgG and cold agglutinins (CA). Retrospectively diagnoses, hematologic parameters and therapy were studied.

RESULTS: 47% (16/34) showed a positive agglutination in at least one test. C3d, ant I, CA and IgG ocurred most frequently (n=9/8/7/6 out of 16). 75% (12/16) had leukopenia (<4000/µl). 50% (8/16) had thrombocytopenia (<150000/µl) and 38% (6/16) showed both. Hypergammaglobulinemia (>16 g/l) was present in 81% (13/16). Only 2 out of 16 DAT+ PTS showed hemolysis. 63% (10/16) of the DAT+ had proven mycobacteriosis (8 atypical) in contrast to only 17% (3/18) of the DAT- PTS ($p<0.01$). Other diagnoses and therapy of the DAT+/- PTS showed no significant difference in prevalence (PcP, CMV, NHL, toxoplasmosis).

CONCLUSION: Autoimmune versus infectious pathogenesis of DAT in AIDS has been discussed in the literature. Our results show a correlation of mycobacteriosis with DAT suggesting rather infectious than autoimmune pathogenesis.

M.B.P.65 INCREASE OF FACTOR VIII ACTIVITY IN HIV INFECTED PATIENTS.

Gafà, Sergio*; Rivasi,P.**; Artioli, A.***; Vezzani,F.*and Tussa,A.*.
Arcispedale S. Maria Nuova, *Divisione Malattie Infettive; **Servizio di Immunoematologia; ***Laboratorio Chimico-clinico, Reggio-Emilia, Italy.

Objective. To demonstrate an abnormal coagulation profile associated with HIV.

Methods. We have evaluated haemostatic function in 20 patients with HIV-infection. All the patients included in the study were treated with AZT. We measured APTT, Fibrinogen, FVIIa, FVIIIa and FXa: Factor VII, VIII and X activity were carried out, using plasma from General Diagnostic, a pool plasma from 20 donors used as control.

Results. These results show not significant difference in APTT, Fibrinogen, Factor VII and X activity, however there is an increase in Factor VIII activity.

	Fibrinogen mg/dl	APTT sec	FVIIa %	FXa %	FVIIIa %
HIV infected patients	283±70	35±13	98±17	98±10	180±34
Controls	285±65	32±9	95±15	94±12	105±20

Conclusion. These preliminary dates should be supported with further investigation to determinate if the changing in Factor VIII activity is related to a FVIII antigen modification and this situation is an epiphenomena to an acute serologic response or it is associated with an hypercoagulability.

M.B.P.66 THERAPY OF SALMONELLA INFECTIONS IN AIDS PATIENTS.

K. Rolston, S. Rodriguez, and P. Mansell. The University of Texas M.D. Anderson Cancer Center, Houston, Texas. USA.

Objective - To evaluate the efficacy and toxicity of newer agents - ceftriaxone (CTX) and ciprofloxacin (CPF) compared to ampicillin (AMP) and trimethoprim/sulfamethoxazole (TMP/SMX) for Salmonella infections.

Methods - Ten AIDS patients with severe Salmonella gastroenteritis were treated with standard or newer agents. Patients were monitored for response, toxicity and recurrence (minimum follow up - 6 months).

Results - All 5 patients treated with AMP or TMP/SMX responded initially but all relapsed - one with bacteremia. Two responded to a 5 day course of I.V. CTX (no relapse). One received only 2 doses of CTX before therapy was stopped for a skin rash. He responded but relapsed 1 month later. Two patients responded to oral CPF. CTX & CPF were well tolerated.

Drug	# of Pts.	Outcome	Follow-up
ampicillin	2	response	relapse
TMP/SMX	3	response	relapse (bacteremia-1 pt.)
ceftriaxone	3	response	relapse-1 pt.
ciprofloxacin	2	response	no relapse

Conclusion - Aggressive therapy of Salmonella gastroenteritis in AIDS patients may prevent bacteremia and dissemination. Agents such as CTX and CPF may be superior to, less toxic, and have fewer resistant Salmonella isolates than standard drugs. These agents have high biliary concentration and may eliminate the chronic carrier state. Oral agents (CPF) may also increase compliance. They need wider clinical evaluation to establish efficacy and optimal length of therapy.

M.B.P.67 SALMONELLA BACTEREMIA AND HIV INFECTION

Ocaña I., De Luis A., Planes A.(*), Pahissa A., Serra E., Martinez-Vazquez J.M.
Departments of Internal Medicine and Microbiology (*). Hospital Valle de Hebrón. Autonomous University of Barcelona, Barcelona, Spain.

OBJECTIVES: to establish the incidence, causative microorganisms and clinical course of salmonella bacteremia (SB) in patients with infection by the human immunodeficiency virus (HIV+).
MATERIAL AND METHODS: analysis of all SB episodes in HIV-positive patients during a period of 3 years and 8 months (April,1985 to December,1988). Study sample with 145 patients with AIDS and 200 HIV-positive patients in other stages.
RESULTS: we found 28 SB episodes in 21 patients, 15 fulfilling the diagnostic criteria for AIDS (CDC,1987) and 6 with generalized persistent lymphadenopathy. There were 16 males and 5 femalesand the mean age was 30 years with a range of 16 to 64 years. Twelve patients were intravenous drug addicts, 6 homosexual, 2 multitransfused and one had hemophilia. The incidence of SB in patients with AIDS was 10.3% (15/145) and in HIV positive without AIDS 3%. The salmonella infection was coincidental with the diagnosis of AIDS in 8 cases, posterior in 5 and previous in 2. Six patients had a total of 7 SB recurrences (SBR) within an average of four months and in all of them SBR was the opportunistic infection that led to the diagnosis of AIDS. Salmonella enteritidis was the causative species in 27 episodes (96.4%). The clinical picture consisted of a simple febrile episode lasting 2 to 45 days in 19 SB (67.8%), pneumonia in 5 cases, gastroenteritis 2 cases, endocarditis one case and fever and a gluteal abcess one case. A favourable response with negative blood cultures was observed in 26 episodes (92.8%), and two patients died 3 and 11 days after the diagnosis, of unrelated causes. Each case was treated with active antimicrobials after in vitro susceptibility testing.
CONCLUSIONS: of note: 1- The high incidence (10.3%) of SB in AIDS patients in our area, almost exclusively (96%) produced by Enteritidis organisms, as a reflection of the high prevalence of this microorganism in our surroundings. 2- A high response rate (93%) with conventional treatment and a relatively lower incidence of recurrences (25%) compared with other series. 3- A close relationship between SB and diagnosis of AIDS.

M.B.P.68 SHIGELLA ENTERITIS AMONG AIDS CASES IN LOS ANGELES

Lieb, Loren; Tormey, M.; Ewert, D.; Wakamatsu P.; Run, G. and Kerndt, P.
Los Angeles County Department of Health Services, Los Angeles, Calif, USA.

Objective. To determine the frequency and distribution of reported shigellosis among AIDS cases in Los Angeles County (LAC).
Methods. The cumulative AIDS and shigellosis surveillance registries in LAC, for 1979 through 1988, were compared to identify cases common to both registries.
Results. Of 5,631 AIDS cases reported in LAC through December 31, 1988, 220 (4%) also had shigellosis; 172 (78%) had *S. flexneri*, 27 (12%) *S. sonnei*, 3 (1%) *S. dysenteriae*, 3 (1%) *S. boydii*, and 15 (7%) were of unknown serotype. Three were female; 121 were white, 61 black, 36 Hispanic, and 2 were among other racial groups. AIDS cases with shigellosis were twice as likely to be black than other racial groups (p<.001) and adult males were four times more likely to be homosexual or bisexual (p<.01) when compared to AIDS cases without shigellosis. The AIDS-defining opportunistic infections cryptosporidiosis, isosporiasis, and herpes simplex were more common among AIDS cases with shigellosis and *pneumocystis carinii* pneumonia was less common compared to AIDS cases without shigellosis. Seven percent of AIDS cases diagnosed prior to 1985 also had shigellosis, compared to 4% of AIDS cases diagnosed in subsequent years (p<.001). AIDS cases with and without shigellosis did not differ with respect to mean age, intravenous drug use, or country of origin. Shigellosis was diagnosed more than 1 month prior to AIDS for 146 (66%) cases, concurrently for 59 (27%) cases, and more than one month following the diagnosis of AIDS for 15 (7%) cases. Blacks and Hispanics were more likely than whites to have concurrent shigellosis and AIDS. *S. sonnei* was diagnosed only among homosexual or bisexual males and *S. flexneri* was more common among blacks (<.05).
Conclusion. Shigellosis is more common among AIDS cases than campylobacteriosis or salmonellosis. Although the proportion of AIDS cases with shigellosis began decreasing in 1985, continued concurrent shigellosis and AIDS, predominantly among homosexual and bisexual men, suggests ongoing high-risk sexual behavior after infection with HIV, particularly among blacks and Hispanics.

M.B.P.69 CLINICAL PRESENTATION AND QUINOLONE (Q) THERAPY OF SALMONELLA IN HIV INFECTION.

Karabulut, Nigahus, Porwancher, R., Cherney, C., Ricketti, A., Friedland, R., St. Francis Medical Center, Trenton, New Jersey USA.

Objective: To review the clinical features and efficacy of Q therapy in HIV+ patients with salmonellosis.
Methods: We treated 17 HIV+ prisoners (10 AIDS, 6 ARC, 1 Sero-positive) with 26 episodes of salmonella infections between 12/85 and 12/88. Sites of isolation included blood (67%), stool (20%), and urine (13%). Intravenous drug abuse prevalence was 94%. For patients who survived 3 months or longer after salmonella infection, treatment was evaluated by dividing patient episodes into 2 groups. Group 1 (G1) was treated with Q antibiotics (14) and Group 2 (G2) was treated with non- Q antibiotics (9). Both groups received initial ampicillin and/or ceftriaxone parenterally for 10-12 days. All isolates were sensitive to these drugs. G1 subsequently received oral ciprofloxacin (11) or norfloxacin (3) for a mean of 28 days. G2 received oral amoxicillin or ampicillin for a mean of 28.7 days.
Results: Clinical and microbiologic follow-up was available in all patients. Interesting clinical features on presentation included pulse-temperature dissociation in 30%, reversible acute renal failure in 11.5%, and concurrent opportunistic infections in 38% of episodes. Relapse rates were (14.3%) in G1 and (77%) in G2 (p=0.004). One out of two failures in G1 was related to non-compliance. The mean follow up period was 4.6 months in G1 and 3.0 months in G2.
Conclusion: In HIV+ patients with salmonellosis, Quinolone therapy appears more effective than conventional therapy in preventing relapses and warrants further study.

M.B.P.70 NOSOCOMIAL INFECTION (NI) IN PATIENTS WITH HIV INFECTION.

Kales, Christopher P.; Holzman, R.S.; Krasinski, K.; LaCouture, R.
New York University - Bellevue Medical Center, New York, U.S.A.

Objective. To compare NI for AIDS patients (AIDS) and those without evidence of HIV infection (NONHIV).
Methods. We matched infection control and HIV census data, collected by active concurrent surveillance programs at Bellevue Hospital. Patients with suspected HIV infection but without AIDS were excluded. Infection rates are expressed as infections per 10^3 patient-days of care. Relative risks are expressed as rate ratios; ratios that differ from 1.0 with $P < 0.05$ are underlined.
Results. During the year 7/87–6/88, there were a total of 27,868 discharges, including 595 with AIDS. NI rates were 3.46 for AIDS, and 1.49 for NONHIV. For adults, AIDS were significantly younger (medians 37 vs 50 years) and more likely to be male (78% vs 59%). Median time to acquisition of first NI was 40 days for AIDS and 16 for NONHIV (P<0.05). 50% of NONHIV NI, but only 17% of AIDS NI were associated with intensive care units. By service, the NI rate ratios were 4.69 (AIDS/NONHIV=10.2/2.18) for pediatrics, 1.55 (3.54/2.28) for medicine, & 3.93 (9.13/2.32) for other acute services. For an intermediate care service, dealing with less acutely ill patients, the rate was 2.91 (2.40/0.82). By site, the rate ratios were 4.51 (1.94/0.34) for bacteremias, 3.41 (0.14/0.04) for gastrointestinal, 2.27 (0.18/0.08) for skin & soft tissue, 2.24 (0.60/0.27) for pneumonia, & 0.97 (0.41/0.43) for urinary infections. Compared to NONHIV, AIDS had more bacteremias due to enteric rods (P<0.01) and enterococci (P<0.05), and more enterococcal urinary infections (P<0.005). Fungi were not more common in AIDS NI.
Conclusion. AIDS are at increased risk for some but not all NI. This results in part from differences in the types of treatment afforded them (e.g. increased IV catheter use) and in part from increased length of stay.

M.B.P.71 BACTEREMIC PNEUMOCOCCAL DISEASE AS THE FIRST MANIFESTATION OF HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION IN ADULTS

Jay Dobkin, MD, W Mandell, MD, H Sethi, MD. Dept. of Medicine, Harlem Hospital, Columbia U. College of P+S, New York, NY, USA.

Disease due to Streptococcus pneumoniae(SP) has been associated with HIV-infected children and adults with symptomatic AIDS/ARC(A/A). We previously reported a steep rise in cases of bacteremic SP disease(BSPD) during the 1980's in patients(pts) at risk (R) for HIV infection but without A/A. From 10/1/87-5/15/88 we prospectively evaluated 103 consecutive episodes(EP) of adult BSPD in 101 pts. Forty-eight of 92 pts(52%) tested were HIV+. Only 8/48 (17%) had A/A. 74%(44/59) of pts with any HIV R were HIV+. Control parenteral drug user(PDU) pts admitted for trauma/surgery were less likely to be HIV+ than SPBD PDU pts [7/18(39%)vs(35/45(78%); p<.005].

Clinical Features in 94 Episodes# of Bacteremic Pneumococcal Disease

Feature	HIV Positive(n=50)	HIV Negative (n=44)
Mortality	7/50 (14%)	11/44 (25%)
Meningitis	3/50 (6%)	4/44 (9%)
Normal CXR	5/50 (10%)	2/44 (4%)
Total WBC	13,072	15,850
T4;T8; T4/T8 Ratio	280*; 621; 0.61*	804; 526; 1.59
Anergy	11/18 (61%)	13/23 (56%)

[#=2 HIV+ pts had 2 eps; CXR=chest xray; T4,T8=lymphocyte subsets/cumm; Anergy=<3mm reaction to 4 antigens; *= p<.001 vs HIV Negative pts]

HIV+ pts with and without A/A had very similar T4 counts and T4/8 ratios.
Conclusion: BSPD occurs more frequently in HIV+ pts without symptoms than in those with A/A. T cell studies suggest advanced immune damage in the non-A/A pts. BSPD may be an important first indication of HIV infection.

M.B.P.72 STAPHYLOCOCCUS AUREUS NASAL CARRIAGE RATE IN PATIENTS WITH AIDS OR ARC.

Marluz P, Raviglione MC, Pablos-Mendez A, Battan R, Ottuso P, Sciemca S, Taranta A. - Department of Medicine, Cabrini Medical Center, NYC, N.Y., USA.

Introduction: A high frequency of infections (especially of intravenous catheters) caused by Staphylococcus aureus (SA) has been observed in patients with AIDS or ARC.
Objective: To assess the frequency of SA nasal carriage among patients with AIDS or ARC.
Methods: The nasal carriage rate of SA was determined in 64 consecutively hospitalized patients with AIDS or ARC within 24 hours from admission. Narcotic addicts were excluded. A group of 64 patients with other diseases was used as a control.
Results: Of 64 patients with AIDS or ARC, 35 (55%) were nasal carriers of SA, as compared to 18 (28%) of 64 control patients (CI 10–42). Recent hospitalization (less than 1 year) did not influence carriage rate, nor did the recent use of antibiotics or zidovudine, although patients on agents active against SA and patients not taking zidovudine showed a lower carriage rate.
Conclusions: The significant SA nasal carriage rate in AIDS or ARC patients may explain the reported high incidence of intravenous catheter-related SA infections in this population.

M.B.P.73

PREVALENCE OF SIGNIFICANT LOWER RESPIRATORY BACTERIAL INFECTIONS IN HIV POSITIVE PERSONS UNDERGOING BRONCHOSCOPY WITH SEMI-QUANTITATIVE BAL CULTURE.

Skahan, Kenneth J., Baughman, R.P., and Frame, P.T. Department of Medicine, University of Cincinnati, Cincinnati, Ohio, USA.

OBJECTIVE. To document the prevalence of significant lower respiratory infections in Human Immunodeficiency Virus (HIV) positive persons with pulmonary symptoms undergoing bronchoscopy. METHODS. All HIV positive persons with pulmonary symptoms referred to our medical center in 1985-1988 underwent bronchoscopy and bronchoalveolar lavage (BAL) semi-quantitative bacterial cultures. RESULTS. Significant lower respiratory bacterial infections (LRBI) were found in 27 of 234 bronchoscopies (11.5% prevalence) defined as > 10,000 CFU's on semi-quantitative culture of BAL fluid. Of the 36 bacterial isolates, the predominant organisms were Strep species (13), H. influenza (9), S. aureus (5), gram negatives (6). Gram stains were positive in 7 of 26 BAL samples. Compared to other HIV positive persons undergoing bronchoscopy, individuals with LRBI's were more likely to have localized disease on chest x-ray (Chi square = 11.5, $p<0.01$) and a higher percentage of neutrophils [16.9±16.7% (mean ±S.D.) vs. 7.3±12.5%, $p<0.001$] on BAL. Differences were not seen between the two groups in regards to age, sex, total white blood cell count, hypoxemia ($PO_2 < 80$), AZT administration, or coinfection with Pneumocystis carinii (Pc) or cytomegalovirus. CONCLUSION. Significant lower respiratory bacterial infections are commonly found in HIV positive persons at bronchoscopy. The fact that they can also co-exist with other pulmonary infections, including Pc, may have important implications for therapy.

M.B.P.74

AIDS-ASSOCIATED URINARY TRACT INFECTION (UTI)

Luiz Paulo J. Marques, O. R. Santos, G. S. Lopes, M. C. Rachid de Lacerda, G. B. Teixera, M. M. R. Fernandes, Clinica Medica III, Escola de Medicina e Cirurgia, Universidade de Rio, Rio de Janeiro, Brazil.

Objectives. To determine if HIV infection leads to predisposition to UTI, caused by non-opportunistic bacteria.
Methods. 303 HIV-infected patients, 280 men and 23 women, were studied during the average period of 6 months. All were screened with urinalysis and nitrite tests. In those with positive tests, urine culture was done. Diagnosis of UTI required more than 100,000 colonies in urine culture.
Results. UTI was found in 19 (6,3%): 17 (6,1%) men and 2 (8,7%) women. Nine patients (8 men and 1 woman) presented previous predisposing factors to UTI (7 submitted to long urinary catheterization, one to renal lithiasis and advanced pregnancy in one), one patient was a woman in reproductive age and only nine men (3,2%), 8 homosexuals and 1 hemophiliac, did not show any other known predisposing factor. In 18 patients enterobacteria were found (mainly E. coli, 12 cases, 63,1%) and in the other (5,3%) Acinetobacter was found.
Conclusion. In our study, HIV infection was not an isolated predisposing factor to UTI caused by non-opportunist bacteria.

M.B.P.75

SEVERE BACTERIAL INFECTIONS IN AIDS PATIENTS

Marone, Piero; Sacchi, P.; Gromi, P.; Gatti, G.
Institute of Infectious Diseases, University of Pavia, IRCCS San Matteo, Pavia, Italy.

Objective.To determine the incidence and type of severe bacterial infections in AIDS patients.
Methods.One hundred and forty-three patients (pts) were analysed retrospectively with respect to sex, age, risk factors and microbiologically proven severe bacterial infections.
Results.Fifty-four episodes of severe bacterial infections were identified in 44 pts (30.7%). There were 36 men and 8 women; ages ranged between 3 and 59 with a mean of 31. HIV infection risk groups: 27 IVDA, 11 omosexuals,2 IVDA-omosexuals, 2 eterosexuals, 1 bisexual and 1 child of HIV-infected women. Twenty-six bacteremias were observed in 24 pts: Salmonella nontyphoid (10), Staph. epidermidis (7), Pseudomonas sp. (2), Clostridium septicum (1), Propionibacterium acnes (1), Streptococcus mitis (1), Serratia mar. (1), Klebsiella ox. (1), Escherichia coli (1) corynebacterium J-K (1). The source of staphilococcal and corynebacterium J-K bacteremias was a central venous catheter (CVC) in 7 pts (7/8). Eighteen pts had mycobacterial infections: tuberculosis (11), non-tuberculous mycobacterial infections (7). Other infections included six episodes of pneumonia and four abscesses. Most pts responded to appropriate antimicrobial therapy.
Conclusion. The incidence of severe bacterial infections in our series is about 30%. Empiric antibiotic therapy may be necessary in these pts before a specific diagnosis is made. Appropriate and prompt therapy is usually effective.

M.B.P.76

BACTERIAL INFECTIONS IN AIDS

Shah, Pramod M., Bolz, A., Helm, E.B. and Stille, W.
University Hospital, Center for Internal Medicine, Frankfurt, Federal Republic of Germany.

From 1-1-1982 till 30-6-1988, 267 patients with AIDS have been treated at our center. Eighty percent were male homosexuals or bisexuals. The second largest group were intravenous drug abusers. Nine hundred and twenty pairs of blood cultures were inoculated in 197 patients. In 35 samples a relevant bacterial pathogen could be isolated. Twenty-four episodes of septicemia (blood culture positive) were diagnosed in 19 patients. The mean laboratory values were: leukocyte count 6800 (range 600-20200), 1 hour sedimentation rate 73.6 mm (23-127), CD4 90 µl (6-359), and CD8 512 µl (99-1082). All but one patient (St. III) were in stadium IV (CDC classification). Staphylococcus aureus (n=8) was the most frequent pathogen, followed by Salmonella spp. (n=5), Streptococcus pneumoniae (n=3), Pseudomonas aeruginosa (n=3), Escherichia coli (n=3), Strep. Group A (n=1), and Staph., coagulase-negative (n=1). Drugs used in treatment were: cefotaxime, ciprofloxacin, clindamycin, co-trimoxazole, imipenem, gentamicin, amikacin, ofloxacin. Seven out of 19 patients died during the septicemia episode. Most of the patients had a variety of other complicating factors.

M.B.P.77

LISTERIOSIS IN PATIENTS WITH HIV INFECTION.

Kales, Christopher P.* **; Holzman, R.S.*.
*New York University-Bellevue Medical Center;
**St. Vincent's Hospital and Medical Center, New York, USA.

OBJECTIVE. To identify the clinical manifestations of listeriosis in HIV-infected patients and determine their responses to therapy.
METHODS. The medical records of all patients admitted to 2 medical centers in NYC from 1981 to 1988 with bacteremias or meningitis due to L. monocytogenes were reviewed. Patients were grouped as either having evidence of AIDS or risk for HIV infection (AIDSorRISK+) or lacking such evidence (AIDSandRISK-).
RESULTS. 30 patients with listeriosis were identified and reviewed. 19 were AIDSandRISK-. 6 patients had AIDS, 1 was seropositive but asymptomatic and 4 were at high risk for HIV infection. While the annual number of cases of listeriosis in AIDSandRISK- was constant, 9 of the 11 AIDSorRISK+ cases occurred between 1985 and 1988, the last half of the survey period. All AIDSorRISK+ patients were male homosexuals or intravenous drug abusers, and all but one were black or hispanic. The clinical syndromes included bacteremia without apparent source in 7 (64%) AIDSorRISK+ and 8 (42%) AIDSandRISK-, meningitis in 3 (27%) AIDSorRISK+ and 5 (26%) AIDSandRISK-, and a single case of endocarditis in each group. 10/11 AIDSorRISK+ were treated with penicillin or ampicillin; 7 were also given an aminoglycoside. All 11 survived; most became afebrile by the fifth hospital day. No relapses were observed. All 19 AIDSandRISK- patients responded, but 2 died of underlying malignancy.
CONCLUSION. From 1981 to 1988, the frequency of listeriosis increased in AIDSorRISK+ but not AIDSandRISK- patients. AIDSorRISK+ patients with listeriosis responded well to standard therapies. Physicians should consider L. monocytogenes when empirically treating AIDSorRISK+ patients with sepsis and meningitis.

M.B.P.78

AIDS RELATED HISTOPLASMOSIS.

JM Parke, SD Nightingale, SM Pounders. Parkland Memorial Hospital, Dallas, TX, USA.

Histoplasmosis was diagnosed in 30 (4%) of 752 AIDS patients seen prior to 12/31/88 at Parkland Memorial Hospital, which serves a region where histoplasmosis is endemic. Histoplasmosis was the initial opportunistic infection except oral thrush in 26 (87%) of these patients. Thirteen patients had positive blood cultures, 9 had positive peripheral smears, 7 had positive bone marrow cultures, 3 had positive bronchoscopies, and 2 had positive skin biopsies. Three were first diagnosed postmortem. Mean survival was 170 days after the procedure that established the diagnosis was performed.

Ten died within 10 days of that procedure. All who survived long enough to receive at least 100 mg amphotericin B survived to complete a full course of amphotericin therapy. Five of the patients were receiving ketoconazole for thrush at the time histoplasmosis developed; 3 of these died before 50 mg amphotericin B could be administered.

These observations suggest that early diagnosis of AIDS-related histoplasmosis (e.g., by peripheral smear or routine surveillance blood cultures) may improve at least its short-term prognosis.

M.B.P.79 DISSEMINATED HISTOPLASMOSIS IN A DANISH AIDS PATIENT.

Smith, Else*; Franzmann, M.**; Mathiesen, L.*
University of Copenhagen, Hvidovre Hospital; *Department of Infectious Diseases; **Department of Pathology, Copenhagen, Denmark.

Objective: To present the first case of disseminated histoplasmosis (DH) in an European AIDS pt.
Methods and Results: A 33-year old HIV-seropositive Danish homosexual with 2 weeks of fever, chills, a slight cough and a weight loss over the last 3 months. Examination showed a Kaposi's sarcoma in the mouth, oral thrush and a temperature of 38.4°C. No lymph node swelling or organomegaly. White blood cell count was 2.700/mm^3 and CD_4 cell count was zero. X-ray of the chest showed diffuse bilateral infiltrates and from the bronchial lavage pneumococcer and candida were cultivated. Therapy was started with penicillin and ketoconazole 200 mg daily. A liver biopsy showed granulomata and a biopsy of the bone marrow was normal. A CAT-scan of the abdomen showed a slight hepatosplenomegaly and several lymph nodes in the retroperitoneum. Six weeks after admission he still had the fever and was loosing weight. Zidovudine 1200 mg daily was started and an explorative laparotomy was done with the excision of a mesenterial lymph node. Histologic examination showed typical H.capsulatum in EM. A histoplasmin skin test and histoplasma serologic test of the urine and blood were all negative. He was treated with i.v. Amphotericin B 25 mg/day for 2 weeks to a total of 4.5 mg/kg. Then the treatment was changed to oral fluconazol 200 mg/day. The patient lived in Venezuela from 1983-1986 but otherwise in Europe. A CAT-scan 2 months later showed regression of the lymph nodes and no organomegaly. Eleven months after the diagnosis of DH he is feeling well on oral fluconazole 200 mg/day without any sign of relapse or other opportunistic infections. CD_4 cell count is 250/mm^3.
Conclusion: DH should be suspected in HIV-positive patients also from non-endemic areas. A detailed travel history is essential. This patient got a much lower i.v. Amphotericin B dose than recommended but it seems to be sufficient when followed by oral fluconazole.

M.B.P.80 CHRONIC SUPPRESSION OF DISSEMINATED HISTOPLASMOSIS IN HIV DISEASE WITH ORAL KETOCONAZOLE

Robert Neihart and J. Brewer. St. Luke's Hospital, Kansas City, Missouri, USA.

Objective. To review the course of ten consecutive patients with disseminated histoplasmosis and HIV disease treated with intravenous amphotericin B (AMB) followed by chronic suppressive oral ketoconazole.
Methods. Clinical and laboratory data was reviewed retrospectively on all patients we have seen with histoplasmosis and HIV (N=11). One case, in which death occurred shortly in AMB treatment, is not included.
Results. Diagnosis was made by smear and culture of bone marrow (N=4), blood (N=2), lung tissue (N=2), colon (N=1), and bronchoalveolar lavage (N=1) Each patient received 1050 to 2400 mg of AMB followed by 400-600 mg ketoconazole orally per day. Patients have been followed from one to 24 months on ketoconazole. Average months of disease free follow-up = 11.5. Two patients relapsed, but remain alive, having been retreated with AMB. One relapse, at 6 months on ketoconazole, was associated with ranitidine treatment. The other relapse, at 21 months, was associated with rifabutin treatment. Two of the 10 patients died. Both died of other HIV related conditions. Both had negative bone marrow exams for histoplasmosis shortly before death.
Conclusions. Chronic suppressive oral ketoconazole may be a reasonable alternative to chronic suppressive AMB in selected patients with histoplasmosis and HIV disease.

M.B.P.81 HISTOPLASMOSIS IN AN AIDS PATIENT TREATED WITH ITRACONAZOLE

Youle, Michael*; Midgley Jennifer*; Shanson, D*; Campbell, C.**; Gazzard, B.*
*St. Stephen's Hospital, London, England, **Mycobacterial Reference Laboratory, London, England.

Objective Histoplasmosis has been described in AIDS cases in endemic areas. We report a case which developed in a severely immunocompromised patient resident in the U.K.
Methods A 34 year old HIV antibody positive patient with a previous AIDS diagnosis of cerebral toxoplasmosis and Mycobacterium tuberculosis in the lung and neck nodes, presented with a two month history of skin lesions on the face and back and painful, swollen left foot. Biopsy of the fifth metatarsal and also of a heaped granulomatous skin lesion showed the large tuberculate macroconidia of Histoplasmosis capsulatum. The patient was Argentinian but had not been in that country for ten years.
Results He was already being treated with ketoconazole 200mg twice daily for oesophageal candidiasis but has since been switched to the triazole itraconazole 200mg daily in an attempt to eradicate the fungus. His lesions have healed completely and feels much better since commencing therapy, he remains well at six months follow up. Treatment in the past has been with intravenous amphotericin B and flucytosine or oral ketoconazole. It is interesting that this patient was already on ketoconazole when he developed the skin and bone lesions suggesting poor drug absorption or a resistant strain.
Conclusions We believe this to be the first AIDS patient to develop this infection in the United Kingdom and to be successfully treated with itraconazole.

M.B.P.82 DERMATOLOGICAL MANIFESTATIONS AND HIV INFECTION

Abreu, E.A.V.; Quinhões, Eleonora Pati; Rachid de Lacerda, M.C.; Serra, M. S.; Sion, F.S.; Morais de Sá, C.A.
Gaffrée & Guinle University Hospital - University of Rio de Janeiro (UNI-RIO) - Brazil.

Objective: To analyse all dermatological manifestations among 409 HIV infected patients.
Methods: We made a retrospective study of all mucocutaneous findings among patients attending our "AIDS" Clinic from November 1983 to August 1988. HIV infection was confirmed by ELISA, Indirect Immunofluorescence and/or Western blot techniques. All mucocutaneous lesions were confirmed by biopsy and/or culture when needed. Patients were evaluated for age, sex, risk group, stage of infection and types of lesions. We did not evaluate treatment or response to treatment.
Results: We found mucocutaneous manifestations in 227 patients (55,5%), 212 male (93,39%), 182 homo/bisexuals (80.17%). Most of the patients presented more than one type of lesion.

TYPE OF LESION	PATIENTS	
	N	%
Kaposi's sarcoma	48	21.15
Oral candidiasis	91	40.10
Other fungal	28	12.33
Viral	65	28.63
Bacterial	31	13.66
Seborrheic dermatitis	56	24.67
Others	64	28.19

Conclusions:
1) Dermatological manifestations are common among our HIV infected patients.
2) It is possible to make a suspicious diagnosis of HIV infection observing the skin.
3) Seborrheic dermatitis,Kaposi's sarcoma and oral Candidiasis were the most common mucocutaneous manifestations.

M.B.P.83 RHODOTORULA RUBRA SEPTICEMIA IN AN AIDS PATIENT WITH AN IN-DWELLING HICKMAN CATHETER.

Causey, Dennis M . Leedom, J.M., and Olsen, C.
University of Southern California, Los Angeles, California, USA.

Objective. To describe a septicemia in an AIDS patient caused by Rhodotorula Rubra. This organism has not been previously decribed as a cause of fungemia in AIDS patients.
Methods. A 42 year old Caucasian male diagnosed with chronic Cryptosporidium diarrhea and receiving central hyperalimentation developed fevers. Blood was obtained from the in-dwelling Hickman catheter for culture on 6 occasions over a 48 hour period. Blood was inoculated into BACTEC NR6A bottles and processed in a BACTEC NR730 system and then plated onto Sabouraud agar. Blood for culture was also obtained using the Dupont Isolator Lysis Centrifugation method and innoculated onto Sabouraud agar. The Hickman catheter was removed. Follow-up blood cultures were obtained.
Results. Blood cultures drawn from the Hickman catheter grew R. rubrum using both culture systems. R. Rubrum has a distinct pink coral color. Following removal of the catheter, peripheral blood cultures yielded no growth and the patient defervesced.
Conclusion. R. Rubrum has been rarely reported to cause septicemia. R. Rubrum may cause septicemia in AIDS patients with Hickman catheters. Catheter removal alone may result in cure without specific anti-fungal therapy.

M.B.P.84 SEPSIS FROM IMPLANTED CATHETERS IN PATIENTS WITH AIDS

Rosenthal, Jonathan H.; Langley, C.; Lederman, M.
Case Western Reserve University, Cleveland, Ohio, USA.

Objective. To assess the frequency of catheter-related sepsis (CRS) in AIDS.
Methods. Review of records of all patients with AIDS (PWA) seen at University Hospitals of Cleveland. CRS was defined as 2 or more positive blood cultures in a febrile patient without other apparent focus of infection.
Results. Thirty-four of 130 PWA had catheters (C) placed; 33 C were evaluable. Indications for C included treatment with amphotericin B, hyperalimentation (HAL), or Ganciclovir (25/33) or need for venous access (8/33). Fifteen episodes of CRS occurred in 12/33 C, with 0.4 CRS/100 C-days. Mean (±SD) time to CRS was 143±92 days. Organisms recovered were S. epidermidis (8), S. aureus (4), Corynebacterium JK (1), P. aeruginosa (1) and C albicans (1). There were no deaths related to CRS and no instances of endocarditis. Mean C life was 147±91 days in infected catheters (IC) and 94±92 days in uninfected catheters (UC) (p=0.1). Dementia was present in 58% of IC and 38% of UC (p=.067). Sixty-seven percent of Mediport®-C and 30% of Broviac®/Hickman®-C became infected (p=.013). Age, sex, race and HIV risk factors were similar in IC and UC. The 2 groups did not differ in duration of AIDS, number of opportunistic infections, Karnofsky status, surgeon, or HAL use.
Conclusions. We found a high overall frequency (36%) of CRS in our PWA. CRS occurred up to 20 times more often than in comparable non-AIDS patients, as reported in the literature. Mediport-C were more frequently associated with CRS than Broviac/Hickman-C. Possible explanations for our high infection rate include presence of dementia, prolonged catheter use at home, and host response factors.

M.B.P.85 EXPERIENCE WITH CENTRAL VENOUS CATHETERS (CVCs) IN PATIENTS WITH AIDS.

Thurn, Joseph R.[1,3]; Miller, C.[2,3]; Johnson, S.[1,3]; Rhame, F.[2,3], and Henry, K.[1,3]
St. Paul Ramsey Medical Center, St. Paul, Minnesota (1); University of Minnesota Hospitals, Minneapolis, Minnesota (2); University of Medical School, Minneapolis, Minnesota (3), U.S.A.

Objective. To describe the indications, complications, and benefits of CVCs in patients with AIDS.
Methods. A retrospective chart review of patients with AIDS who had CVCs surgically placed at our institutions was performed. CVC infections were identified according to Centers for Disease Control (Atlanta) criteria.
Results. From 9/1/83 to 12/1/88, 45 patients with AIDS had 51 CVCs placed. Data was available for 40 patients with 44 CVCs (including 22 Hickmans and a variety of other CVCs). Most (36) were homosexual/bisexual males, one was a heterosexual female, and the mean age was 35.8 yrs (range 22-65). Indications for CVCs (not mutually exclusive) included: weight loss/diarrhea (24), antiviral therapy (15), antifungal therapy (12), antibacterial therapy (9), chemotherapy (3), and pain control (2). Hyperalimentation and blood products were received by 28 and 20 patients, respectively. CVCs were in place for a mean of 87.9 days (range 1-317) with 11 CVC-related infections in 9 patients (with 10 CVCs). The overall infection rate was .28/100 CVC days. Infectious complications seen included 7 bacteremias (due to *S. aureus* (3), coagulase negative staphylococci (2), *C. albicans* (1) enterococcus (1)), and 4 exit-site infections. There was no significant relation observed between CVC infection and the number of CVC lumens, administration of hyperalimentation, or person caring for the CVC (patient/relative versus nurse). Noninfectious complications included; pneumothorax (2), severed CVC (2; 1 deliberately in a suicide attempt), CVC thrombosis (2), and one placement into a mammary vein. No CVC-related deaths occurred and conditions for which CVCs were placed improved in 26 patients.
Conclusion. CVCs in AIDS patients may be placed for a number of indications, are generally well tolerated and, when compared to historical controls involving other immunosuppressed patients, have an acceptable level of infectious and other complications.

M.B.P.86 INDWELLING RIGHT ATRIAL CATHETER(IAC) INFECTIONS IN AIDS PATIENTS.

Skoutelis, Athanasios; Phair, J; Sterkel, C; Von Roenn, J; MacDonell, K; and Murphy, R; Northwestern University Medical School, Chicago, IL, U.S.A.

Objective: Evaluate the risk of infection from IAC in AIDS patients(pts).
Methods. Medical records of AIDS pts who had Hickman or Portacath catheters from 9/1/85 to 8/31/88 were reviewed. Pts with a diagnosis of solid tumor, lymphomas, acute and chronic leukemias served as control group. Catheter related infections (CI) were defined as bacteremia(B), exit infection (E), tunnel infection (T) or any combination of the above. All catheters were inserted by the same group of surgeons and all pts were instructed in their care by the same specialists.
Results. 48 AIDS pts had 14 CI(1E, 1T, 4B, 5BE, 3BT). 130 control pts had 14 CI(2E 1T, 7B, 3BE, 1BT). The results are tabulated below:

	Infections/1000 catheter days	% infections	Mean catheter days
AIDS	1.99	29.2	146
Control	0.47	10.8	229
p value	0.0001	0.0002	

The organisms isolated were(study/control): S.epidermidis, predominantly slime positive, (3/7), S.aureus (7/4), P.aeruginosa (3/0), Xanthomonas maltophila (2/0); other gram negative (0/1), fungi (1/2). 70% of the infected AIDS pts had a CD4 cell count less than 20/mm^3. All infected pts were p^{24} antigen positive versus 20/30 non-infected AIDS pts.
Conclusion. CI are more frequent in AIDS pts when compared to other immunocompromised populations despite fewer catheter days.

M.B.P.87 INFECTIONS AND COMPLICATIONS OF INDWELLING CENTRAL VENOUS CATHETERS (CVC): COMPARISONS BETWEEN PATIENTS (PTS) WITH AIDS VS. OTHER ILLNESSES (NON-AIDS)

Saltzman, Brian R., Perlman DC, Levey DI, Sturm D, Kelly L, Salomon N, et al. Beth Israel Med. Ctr., New York, NY,USA.

Objective: There is concern about placing CVC in AIDS pts, especially intravenous drug users (IVDU). This study was performed to determine the rates of infections and other complications of CVC in pts followed by the Beth Israel Home Care Department, identify factors associated with CVC complications, and compare rates of complications in pts with AIDS vs. non-AIDS.
Methods: Retrospective chart review of pts followed during 1986 using a detailed standardized data collection form.
Results: To date, charts of 48 pts have been reviewed. 15 were not evaluable. 33 pts were analyzed; 19 (58%) AIDS, 14 non-AIDS (carcinoma, 6; congestive heart failure, 3; Crohn's disease, 2; other, 3). There were 22 Hickman CVC in 19 AIDS pts, and 16 CVC in non-AIDS pts (12 Hickmans, 3 Infusaports, 1 triple lumen CVC). CVC were placed for antibiotics (Abx), 16; Abx and total parenteral nutrition (TPN), 3; TPN, 6; other, 5.

		Median # of Catheter Days (CD) [Range]		Septic Episodes	
	N	In and Outpatient	Outpatient	#	(#/100 CD)
AIDS	22	86 [13-344]	54 [0-322]	5	(0.20)
non-AIDS	16	41 [24-407]	39 [4-345]	5	(0.38)

Organisms isolated in AIDS pts were: S.aureus (1), S.epidermidis (1), gram negative bacilli (3), yeast (1). Organisms isolated from non-AIDS pts were: S.epidermidis (2), S.viridans (1), Salmonella sp. (1), yeast (1). One pt in each group had an exit site infection. There were 5 mechanical complications; 3 in AIDS pts, 2 in non-AIDS. Sepsis was not associated with: frequency of accessing the CVC, or care of CVC by nurse vs. pt or family, either overall or within groups. There were no episodes of sepsis among IVDU with AIDS.
Conclusions: 1. Observed infection rates were comparable to those previously reported in non-AIDS pts. 2. We identified no increased risk of infectious or mechanical complications of CVC in AIDS pts vs. non-AIDS. 3. These data suggest that home infusion therapy in AIDS pts carries an acceptable risk.

M.B.P.88 PHARMACOCINETIQUE (SANG-LIQUIDE RACHIDIEN) DE FORTES DOSES D ACYCLOVIR IV CHEZ LES PATIENTS HIV.

Chavanet P, Buisson M, Lokiec P*, Aho S, Bielefeld P, Waldner A, Portier H. Hopital du Bocage BP1542 21034 Dijon cedex *CRH St Cloud 92000 France.

Le but de cette etude etait d etudier la possibilite d obtenir de fortes concentrations d ACV administre par voie veineuse sachant que les infections du groupe herpes sont frequentes au cours de l'infection HIV et que des souches de moindre sensibilite a l acyclovir ACV ont ete isolees (Tka. Tkd)
Méthodes: 33 patients 24-36 ans dont 10 HIV-(5 meningites) ayant des fonctions renale et hepatique normales ont reçu ACV 50 mg/kg en perfusion iv de 3h associe a probénecid 1 g po Les dosages dans le sang et le liquide cephalorachidien (LCR) ont ete realises par radioimmunologie (umol/l)
Résultats la tolérance a ete bonne cephalees, lombalgies, fievre, augmentation de la créatinémie et des transaminases sont survenus en cas de perfusion trop rapide 47 prelevements sanguins et 17 LCR ont ete realises apres la fin de la perfusion (tableau) aucune accumulation n a ete observee la decroissance des concentrations sanguines etait lineaire.

concentr ACV (umol/l)	5min	3h	6h	12h	15	24h	48h
sérum m (n)	197(20)	88(5)	32(10)	3.7(6)	1.64(1)	0.36(3)	0.024(2)
LCR m (n)	5.25(5)	11(5)	10(4)	9(3)			

Les parametres déduits sont les suivants

	AUC umol.h /l	t1/2 h	VD l/kg	Cl Tot l/h	R AUCsang/LCR
sang m±ds	647 ± 92	2.12±0.1	0.97±0.1	0.33±0.06	0.82
LCR m±ds	536 ± 77	28±12			

Conclusions ACV 50 mg/kg en perfusion de 3h permet d obtenir rapidement des concentrations sanguines et rachidiennes prolongees superieures a la plupart des ID50% de HSV1 et 2 Tkd et Tka. de VZV HHV6. EBV et CMV

M.B.P.89 HICKMAN CATHETER INFECTIONS IN AIDS

Raviglione M C, Battan R, Pablos-Mendez A, Aceves-Casillas P, Mullen M P, Taranta A.
Department of Medicine-Cabrini Medical Center, New York, NY-USA

Objective: To determine the incidence of Hickman catheter (HC)-related infections in patients with AIDS compared to patients with other diseases.

Methods: We reviewed the medical records of 69 patients who underwent 71 HC insertions during a one-year study period.

Results: 46 HCs were placed in 44 patients with AIDS and 25 in 25 patients with other diseases. Eighteen infections occurred: 16 in AIDS patients, 2 in the control group (p<0.05). Among patients with AIDS there were 5 exit site infections (3 bacteremic), 5 septicemias, 2 tunnel infections (bacteremic), 1 septic phlebitis; and 3 probable HC infections. Staphylococcus aureus was the only pathogen in 12 cases, and was present in 2 mixed infections (87%). S. epidermidis was isolated alone in 2 patients and as part of mixed infections in 2 other cases (25%). Mean onset of HC infection was 32 days, but 7 patients developed infection in the first 8 days after insertion; in all of them fever was present while leucopenia occurred only in 3. Two patients died. The rate of HC infection was 0.47 per 100 catheter days in AIDS and 0.09 in the control group.

Conclusions: The high rate of HC infections in AIDS underscores the need of using HC only when absolutely necessary. Antistaphylococcal agents should be evaluated for prophylaxis of early HC infections.

M.B.P.90 INVASIVE ASPERGILLOSIS (IA) IN AIDS: CLINICAL MANIFESTATIONS AND PREDISPOSING FACTORS

Salomon N, Perlman, David C, Saltzman BR, Klapholz A, Talavera W, et al. Beth Israel Medical Center, Mount Sinai School of Medicine, New York, NY, USA.

Objective: Describe clinical manifestations of IA in patients (pts) with AIDS; evaluate the presence of predisposing factors.
Methods: Identification of AIDS pts with IA by discharge diagnoses during the period 1984-8. Charts reviewed retrospectively.
Results: Six cases of IA in AIDS pts were diagnosed during the study period. Over 2000 pts with AIDS were admitted to the medical center during that period; a minimal relative frequency of 0.3%. All pts were male; 4 White, 2 Black; 5 homo/bisexual, 1 intravenous drug user. All cases were confirmed histologically. Four of 6 pts had necropsies. 5 cases were diagnosed antemortem [transbronchial biopsy (2), transthoracic needle aspirate (1), open lung biopsy (1), renal biopsy (1)], 4 of which were confirmed at necropsy; 1 case was initially diagnosed at necropsy. Sites of involvement included: lungs, 5; trachea, 2; mediastinal lymph nodes, 2; kidney, 1; brain, 1; thyroid, 1; myocardium, 1. Initial presentations were pulmonary in 5, and renal in 1. All pts with pulmonary IA had fever, cough and wheezing; 3/5 had chest pain. Chest x-rays showed diffuse infiltrates in 3, and focal cavitary infiltrates in 2. The pt with renal IA presented with fever, flank pain, pyuria, and renal insufficiency. All 6 had recognised predisposing factors: high dose corticosteroids (CS) for 2-3 weeks during the month prior to the diagnosis of IA in 3 (2 for PCP, 1 CNS toxoplasmosis); CS (for PCP) and granulocytes < 1000 in 1; granulocytes < 1000 in 1; intravenous drug use and CS (for adrenal insufficiency) 4 months prior to the diagnosis of IA in 1.
Conclusion: 1. In this series, IA in pts with AIDS was uncommon. 2. IA in pts with AIDS was only seen in association with known predisposing factors.
3. Therapeutic use of corticosteroids may increase the likelihood of invasive aspergillosis in pts with AIDS.

M.B.P.91

CRYPTOCOCCOSE, HISTOPLASMOSE AFRICAINE ET SIDA AU CONGO

CARME Bernard, MBITSI A., MOULEY A., ITOUA-NGAPORO A., KBIKILI B., AYA G.M., et al.
Centre Hospitalier et Universitaire de Brazzaville, CONGO.

OBJECTIF. Rapporter la forte fréquence actuelle de la cryptococcose contrairement à l'histoplasmose africaine jamais diagnostiquée au cours du SIDA au Congo.
METHODES. Il s'agit d'une enquête rétrospective sur dossiers couvrant la période 1981-1988 menée en milieu hospitalier à Brazzaville.
RESULTATS. Cryptococcose. Cette mycose, pratiquement inconnue localement avant 1984 (3 cas rapportés), est diagnostiquée de plus en plus souvent. Associée à l'infection à VIH dans la quasi-totalité des cas, elle touche surtout l'adulte jeune avec une nette prédominance masculine (sexe ratio 3,3 pour 38 cas) contrairement au SIDA local (sexe ratio 1,1).

L'histoplasmose africaine (H.duboisii) ne semble pas constituer, pour l'instant, une complication mycosique du SIDA alors que c'est le cas pour l'histoplasmose américaine (H.capsulatum), en particulier aux USA. Non exceptionnelle en Afrique Noire où elle sévit surtout chez des sujets vivants, ou ayant vécu en milieu rural, l'histoplasmose africaine n'a jamais été diagnostiquée dans notre enquête chez un sujet atteint de SIDA. Son incidence, faible, reste stable depuis une dizaine d'années.

	1981	1982	1983	1984	1985	1986	1987	1988	Total
Cryptococcose	1	0	1	0	3	7	9	18	39
Histoplasmose africaine	1	2	3	1	1	1	1	1	11

CONCLUSION. La fréquence élevée de la cryptococcose constatée depuis l'avènement du SIDA contraste avec le nombre faible et constant des cas d'histoplasmose africaine jamais diagnostiquée dans un contexte d'immunodépression.

M.B.P.92

A MULTICENTER TRIAL ON THE EFFICACY AND SAFETY OF FLUCONAZOLE IN THE TREATMENT OF OPPORTUNISTIC FUNGAL INFECTIONS, SPONSORED BY THE ITALIAN NATIONAL INSTITUTE OF HEALTH.

S. Vella*, D. Greco*, M.G. Agresti*, A. Cassone*, G. de Crescenzo**, M.P. Ruffilli**.
*National Institute of Health, Rome, Italy; **Medical Department, Pfizer Italiana S.p.A., Rome, Italy.

Infectious complications are the most frequent cause of death in patients with HIV infections. In Italy, AIDS patients, who are mainly drug addicts, present a high incidence of fungal infections; a 62% incidence has been estimated for oropharyngeal candidiasis, 35% for esophageal and disseminated candidiasis (the incidence of infections caused by candida thus appears to be higher than that for Pneumocystis carinii pneumonia), and 2.6% for cryptococcosis. In ARC patients, a 46% incidence of oropharyngeal infections caused by candida has been calculated. Treatment of these infections appears to be difficult owing to the toxicity of the main antifungal agents available. Fluconazole, a new bis-triazole antifungal agent, proves to be well absorbed by the gastrointestinal tract after per os administration and moreover may also be administered by intravenous route. It reaches high concentrations in the CSF and in experience to date presents an excellent safety profile. Within the framework of a program coordinating national clinical trials for the treatment of HIV infections and for the prophylaxis and treatment of opportunistic infections, the Italian NIH sponsored a multicenter research project in order to assess the efficacy and safety of fluconazole in the treatment of patients with severe systemic fungal infections. Within the framwork of this project, a study on candida isolates will also be done in order to correlate the individual biotypes with the different patterns of virulence and resistance to the various antifungal agents.

M.B.P.93

PARACOCCIDIOIDOMYCOSIS AND HIV INFECTION

Pedro, Rogerio Jesus; Aoki, F.H.; Branchini, M.L.; Lima, J.L.; Abreu, W.B. and Dias, M.B.S.
UNICAMP, Campinas, Sao Paulo, Brazil.

We report the occurrence of paracoccidioidomycosis in 2 HIV infected patients. During follow-up for AIDS, the first patient presented high fever and enlarged liver and spleen. Plain files of the abdomen, abdominal ultrassound and CT scan showed solid nodules with calcifications in the spleen. Both the direct smear and the culture of a bone marrow aspirate yielded Paracoccidioides brasiliensis. The patient died of acute disseminated Paracoccidioidomycosis. The second patient was an homosexual man wich presented a mass on the right lower abdomen and inguinal region. He was seropositive for anti-HIV and a biopsy of the mass showed the association of Hodgkin's disease (mixed cellularity type) and Paracoccidioidomycosis. With the expanding AIDS epidemic we believe this report emphasizes the need to consider Paracoccidioidomycosis in HIV infected persons in countries where this mycosis is endemic. We also suggest the inclusion of Paracoccidioidomycosis as a potential opportunistic infection in these areas.

M.B.P.94

DISSEMINATED INFECTION DUE TO PENICILLIUM MARNEFFEI IN A HIV POSITIVE PATIENT

Coen, Massimo; Viviani, M.A.*; Rizzardini, G.; Tortorano, A.M.*; Bonaccorso, C.**; Quirino, T.
1st Dept. Infect. Dis. and**Microbiol. Lab., L. Sacco Hosp.;
*Inst. of Hygiene, University of Milan, Milan, Italy

A disseminated infection due to P.marneffei is described as the first case observed in Italy. The infection was diagnosed in a 33 yrs old patient, a IV drug abuser infected with HIV, who visited Thailand several times during the last two years.
The patient was admitted to the hospital because of fever, productive cough, skin papules and pustules spread on the face and two skin nodules at both hands. The immunity of the patient was severely compromised(WBC 2100/mm^3, lymphocytes 12%, T4 5%). P.marneffei was isolated from several blood cultures, sputa, scraping of the skin lesions of the face and from the biopsied nodule. The yeast-like tissue cells were observed in the histological sections of the nodule and in the sputum smears.
The patient was treated for 6 weeks with IV Amphotericin B(total dose 1400mg) associated with Flucytosine(150 mg/Kg/die)for the first 3 weeks. Prompt clinical improvement and sterilisation of biological samples were obtained within 10 and 20 days of treatment respectively. Itraconazole was then administred as maintenance therapy(400 mg/die during the first month, 200 mg afterward). No relapse was observed during the first 2 months follow up.

M.B.P.95

INVASIVE ASPERGILLOSIS - AN AIDS TYPICAL OPPORTUNISTIC INFECTION?

Grosse, G.*, Staib, F.**, Seibold, M.**, Heise, W.***, Artigas, Juan*
Auguste-Viktoria-Hospital (AVH), Berlin, Pathology* and Department of Infect. Disease***, and Robert Koch-Institut, Department of Mycology**, Berlin, FRG.

Objective. Among 50 autopsies of deceased AIDS patients of the AVH 3 cases of an invasive Aspergillus infection were found. Repeated mycological examination of 10 AIDS patients with a Cryptococcosis had shown that there is no equivalent readiness for an aerogenic infection with Aspergillus spp. and Cryptococcus neoformans. The uniform immunodeficiency is the only disposition for the Cryptococcosis, but an Aspergillosis develops only under other additional disposition factors.
Methods. The histological examinations of the organs of the 3 autopsy cases included Grocott's methamine silver staining and immunohistochemical examinations with monoclonal antbodies against Cytomegalovirus (CMV)-antigen. The cultural fungus diagnosis was carried out with tissue particles put in the agar.
Results. In the 3 autopsy cases we found an invasive infection with Aspergillus fumigatus. In all these cases there was a terminal phase of AIDS with a double infection of the lungs with Pneumocystis carinii (Pc) and CMV. In the case 1 a leucopenia was mainly responsible for the Aspergillus infection, in the case 2 a corticoid therapy of 5 months, and in the case 3 a preciding chronic lung disease, a severe emphysema.
Conclusions. The definite criteria of the disposition for the invasive Aspergillosis of the 3 AIDS patients were independent of the HIV infection. The invasive Aspergillosis is not a typical opportunistic infection of AIDS.

M.B.P.96

FLUCONAZOLE TREATMENT FOR FUNGAL INFECTIONS IN ARC AND AIDS

Gritti Francesco M., Raise E., Verrini V., Di Giandomenico G., *Lenzi G.
Infect. Dis. Dep. & *Clinical Pathol., Osp. Maggiore, Bologna, Italy

Objective. To evaluate prospectively efficacy and safety of single daily dose Fluconazole (F) in the treatment of fungal infections in ARC and AIDS.
Method. 1) F, 400 mg on day 1 and 200 mg thereafter p.o. or i.v., was given in an open controlled trial to: a) 1 bronchial and 14 esophageal candidiasis (BC and EC); b) 3 disseminated Cryptococcosis (DC) as first-line therapy and 2 cryptococcal meningitis (CM) as maintenance therapy after a 30 day course of Amphotericin B+Flucytosine. 2) Tretment of oral candidiasis (OC) was evaluated in 16 patients (pts), 8 ARC and 8 AIDS, randomly assigned to F, 200 mg on day 1 and 100 mg thereafter p.o., or to Ketoconazole (Kc), 200 mg bid p.o., 8 ARC and 10 AIDS. Controls wre performed before, during and after therapy.
Results. Cure rates were: 1) 1/1 for BC, 11/13 (84.6%) for EC, with a mean dose of 235 mg F given for a mean of 31 days, with 2 drop-outs; 2) 1/3 DC cured with a 42 day F course, 1 dead on day 6 and 1 discontinued on day 10 because of inefficacy; 3) no recurrencies of CM in 2/2 after 6 months maintenance therapy on F; 4) 81.2% cure of OC with F at a mean dose of 108 mg x 15.9 days versus 77.8% with Kc at a mean dose of 375 mg x 15.9 days. F was discontinued in 2 pts because of cutaneous rash (5.5%). An overall 19.4% of F-treated pts had moderate elevation of liver function tests, mostly in individuals with preexistent liver disease and no differences were noted between F versus Kc.
Conclusion: F is effective and safe in the treatment of AIDS' fungal infections.

M.B.P.97 VISCERAL LEISHMANIASIS AS HIV-ASSOCIATED INFECTION. REPORT OF 6 CASES.

Altés J.*; Salas, Ana*; Riera M.**; Balanzat J.** and Villalonga C.*.
*Hospital Son Dureta (Mallorca), and **Hospital Can Misses (Ibiza),
Balearic Islands, Spain.

Objective. To report visceral leishmaniasis (VL) cases observed among HIV infected adult patients in two hospitals from Mediterranean islands known as Leishmania donovani endemic area.
Methods. We retrospectively review all cases of VL diagnosed among adult (>14 years old) patients seen in our hospitals from 1985 to the end of 1988. We report all cases in which HIV infection was also detected, with special reference to the clinical and immunological status, and treatment outcome.
Results. From 1985 to 1988, 9 cases of adult VL have been diagnosed in our two hospitals. In 6 of the 9 cases HIV infection was also detected. Three patients had history of intravenous drug abuse, 1 patient acquired HIV infection through infusion of commercial coagulation factors to reverse coumarin effect, and 1 patient denied any previous risk behaviour. Four patients are men. Age ranged from 18 to 70 years. Two patients refered close contact with dogs. Fever and leukopenia were initially present in all cases. VL was the first severe infection in all patients, and in 3 cases Salmonella (nontyphoid) was recovered from blood cultures during the course of VL. CD4 lymphocytes were < 500/mm3 in all cases. Diagnosis of VL was made by Giemsa stain of bone marrow aspirates. High titers of Leishmania antibodies were found in all cases in which they were tested. Meglumine antimoniate (Glucantime) therapy was used in all cases. Two patients showed clinical improvement, without apparent relapse. Three patients didn't show clinical response to treatment, and two of them died from VL. Three patients met AIDS case definition criteria (1 wasting syndrome, 1 recurrent Salmonella septicemia, 1 candidiasis of esophagus).
Conclusion. Visceral leishmaniasis may be the first severe infection in HIV-infected patients. In these cases often runs an unfavourable course despite appropiate therapy. Like others, we propose that adult VL should be considered as opportunistic infection in HIV infection, and included in surveillance AIDS case definition. All adult patients with VL should be studied to rule out HIV infection, even in endemic areas.

M.B.P.98 Unusual diagnosis of leishmaniasis in AIDS

Ocaña I., De Luis A., Irreguible B.(*), Vallespi T.(*), Torrabadella M (*),. Martinez-Vázquez J.M.
Departments of Internal Medicine and Hematology (*). Hospital Valle de Hebrón. Autonomous University of Barcelona, Barcelona, Spain.

Visceral leishmaniasis is an endemic disease in Spain with a distinctive clinical picture. We report two patients with AIDS in whom the diagnosis of leishmaniasis was established from unusual pathologic materials.
Case report Nº 1 29-year-old male, bisexual, HIV-positive, with history of recurrent salmonellosis and cerebral toxoplasmosis. In January 1988, he was admitted with severe granulocytopenia , Pseudomonas aeruginosa septicemia and disseminated intravascular coagulation. He was again readmitted in March 1988, with an upper gastrointestinal bleeding. An endoscopy revealed gastric Kaposi's sarcoma lesions and the biopsy of such lesions showed infestation by leishmanias. There was improvement of the patient general condition after treatment with sodium stibogluconate at a daily dose of 600 mg. In spite of this adequate treatment, a subsequent bone marrow aspirate still showed the presence of leishmanias.
Case report Nº 2 36-year-old patient with hemophilia type A, multitransfused, with chronic liver disease and HIV positive serology since October 1986. In October 87, he was diagnosed of intestinal cryptosporidium infection. One month later he is admitted with cough, expectoration and fever of three week duration and a diffuse reticulo-nodular pattern on the chest x-ray. Pneumocystis Carinii infection was demonstrated on the bronchoalveolar lavage (BAL) specimens, and there was clinical improvement after three weeks of cotrimoxazole. The cytologic analysis of the BAL specimens revealed the presence of abundant macrophages replete with parasites with the characteristic features of Leishmania Donovani. A treatment with 800 mg a day of sodium stibogluconate was administered during 10 days, but the patient expired 15 days later.
Conclusions: 1- We would like to draw attention to the presence of atypical clinical forms, with limited clinical expression and a poor treatment response. 2- It is likely that some of these infections may pass unnoticed since many of their clinical features may be ascribed to other coexisting circumstances such as drugs, liver insufficiency or to the HIV infection itself. 3- The finding, thus far unreported, of protozoa in BAL or gastric biopsies of Kaposi's sarcoma, should encourage the search for this organism, even in the absence of clinical clues to suspect this infection.

M.B.P.99 HIV SEROLOGY AND VISCERAL LEISHMANIASIS IN CAMEROON

FOMEKONG, E.* ; ZEKENG, L. ** ; KAPTUE, L. ***
* C.U.S.S. YAOUNDE, CAMEROON ** UNIVERSITY TEACHING HOSPITAL YAOUNDE, CAMEROON *** MINISTRY OF PUBLIC HEALTH, YAOUNDE, CAMEROUN.

Objective. To do a study on the seroprevalence of HIV1 and HIV2 antibodies among patients with visceral leishmaniasis (V.L.) in the region of Kousseri (Far North of Cameroon).

Methods. Of 46 patients (22 males, 24 females) with clinical suspicious signs of V.L. (deteriorating general state, prolong fever, anemia, liver and/on spleen enlargement) specific tests were done (full blood count, leishmaniasis serology, May Gründwald Giemsa Stein on bone marrow smears), then HIV1 and HIV2 serology.

Results. The diagnosis of V.L. was confirmed on 9 patients. Out of these 9 patients 1 was found HIV1 positive. None was found HIV2 positive.

Conclusion. V.L. should be considered as an opportunistic infection of AIDS.

M.B.P.100 Tropical diseases of HIV patients in non-endemic countries: A case of viscerale Leishmaniosis and a case of tropical Pyomyositis

Elsing,C. , Erckenbrecht, J.F. , Borchard, F.+, Strohmeyer, G.
Department of Medicine and Pathology+, University of Düsseldorf, 4000 Düsseldorf, Moorenstraße 5, FRG.

Tropical diseases such as viscerale Leishmaniosis are often reported in HIV patients from tropic, subtropic and mediterranian countries. We report 2 cases. Among 220 HIV patients seen at the Department of Medicine, University of Düsseldorf, in 1988, we found 2 patients (1%) with a tropical disease. Case 1: A 31 year old male i. v. drug abuser presented with hepatosplenomegaly, pancytopenia, hypergammaglobuliamia and peripheral lymphomas. Bone marrow aspiration and biopsy showed visceral Leishmaniosis. He was successfully treated with sodium stibogluconate. Case 2: A 29 year old female HIV patient, infected by heterosexual contact, was admitted to the hospital for persistent fever and abdominall pain. CT-scan showed pyomyositis and abscesses of left psoas muscel. Operative drainage and microbiological evaluation excluded Mycobacterium tuberculosis but revealed hemolytic Streptococcus group A as the etiologic agent. Pyomyositis was previously thought to be limited to the tropics, but this patient had never left W.-Germany.
Conclusion: Tropical diseases can be found in HIV patients even outside endemic areas.

M.B.P.101 DETECTION OF HIV-1 IN CEREBROSPINAL FLUID (CSF): CORRELATION WITH PRESENCE AND SEVERITY OF THE AIDS DEMENTIA COMPLEX

Paul, Morris D; Brew, BJ; Khan, A; Gallardo M; Price, RW.
Memorial Sloan-Kettering Cancer Center, New York, NY, USA.

Objective: To assess the presence of HIV-1 in CSF by antigen capture and virus isolation in relation to severity of the AIDS dementia complex (ADC).
Methods: P24 was assessed by antigen capture (Abbott) and by virus isolation (using PHA-stimulated PBL's as indicators) in CSF and serum/blood samples from HIV-1-infected patients at various stages of ADC at the time of clinically-indicated lumbar puncture. Results were correlated with clinical ADC stage.
Results:

ADC Stage	Number of Samples	p24 Antigen		HIV-1 Isolation	
		CSF	Serum	CSF	Blood
		(% Positive)			
0-0.5 (normal-equivocal)	34	0	44	21	90
1 (mild)	28	7	44	25	86
2 (moderate)	18	22	67	50	100
3 (severe)	8	43	100	25	100

Correlations: ADC Stage vs CSF & Serum Ag (p<.0001) vs CSF & Serum Culture (NS).
Conclusion: While p24 in both CSF and blood correlate with ADC Stage, its detection in CSF is insensitive to mild-moderate disease and in blood is relatively nonspecific. Likewise, isolation of HIV-1 from both fluids is nonspecific, and thus, neither method is highly useful for clinical diagnosis. The increase in CSF antigen with falling isolation rate remains unexplained. These results suggest that brain dysfunction may not relate to virus replication within the brain in a simple fashion.

M.B.P.102 CEREBRAL ABCESS CAUSED BY TRYPANOSOMA CRUZI IN A PATIENT WITH AIDS

Matias Kronfeld*, E. Sprinz*, A. Cavalcanti*, A. Carneiro*, L. Severo**, *Hospital de Clinicas de Porto Alegre, Universidade Federal do Rio Grande do Sul; **Instituto de Pesquisas Biologicas, Porto Alegre, Brazil.

Objective. To report a cerebral abcess caused by Trypanosoma cruzi.
Case Report. An 18 year-old white woman with factor VII deficiency arrived at hospital with fever, focal neurological signs and a history of convulsions. She came from the southwest region of Rio Grande do Sul state. A cerebral TC showed multiple cerebral lesions. The liquor had a lymphomonocyte predominance (91%) and low glucose level. Bacteriologial, fungal and immunological exams were negative. Amphotericin B, anti-tuberculous and anti-toxoplasmosis drugs were empirically started in a sequential form, without any improvement. A new lumbar puncture showed Trypanosoma cruzi; unfortunately, it was too late, and the patient died before any treatment could be started.
Conclusion. This is the first case we have noticed of a cerebral abcess caused by Trypanosoma cruzi. It is important to remember that HIV-associated opportunistic infections depend on pathogen prevalence in a certain region and the knowledge of the place of origin of the patient will aid in the search of a diagnosis (the southwest of RS is an endemic region of Chagas' disease, which is caused by Trypanosoma cruzi).

M.B.P.103 ROLE OF PULMONARY FUNCTION TESTS(PFT) AND CD4 LYMPHOCYTE COUNT FOR DIAGNOSING LUNG COMPLICATIONS IN AIDS

D.Parra,*B.Clotet,H.Sala,J.Ruiz,J.Morera. Pneumology and *Infectious Diseases Unit,Hospital de Badalona"Germans Trias i Pujol",Spain.

Objective: To assess the value of PFT and CD4 lymphocyte count for an early diagnosis of pulmonary diseases in HIV seropositive homosexual patients. Material: 33 HIV-seropositive homosexual asymptomatic patients.All denied drug abuse;22 out of 33 were included in stage III and 12 in stage IV-C2 Methods : We determined:Forced Expiratory Volume in one second(FEV1),Forced Vital Capacity(FVC) and Carbon Monoxide transfer Factor(TLCO).Simultaneously CD4 lymphocyte count were also evaluated.Ten out of 33 have had a previous TLCO determination.According to the TLCO obtained we divided patients in 3 groups that were submitted to diferent procedures.Results: Group A(normal PFT): 27 patients,CD4 X:678 x mm3;Group B(normal FEV1 and FVC, TLCO:65-80%):6 patients,CD4 X:618 x mm3(bronchoscopic and histologic abnormalities but without opportunistic infections nor Kaposi´s Sarcoma);Group C(mild restrictive disease,TLCO below 65%):4 patients, CD4 X:191 x mm3, all had Pneumocystis carinii pneumonia (PCP).A table showing all methods and results would be presented. Conclusions: 1-TLCO between 65-80% is seen in HIV-seropositive patients in whom PCP is ruled out,although histopathologycal findings have demonstrated inespecific interstitial pneumonitis.2-TLCO below 65% even in asymptomatic patients with normal chest x-ray must encourage to further explorations since PCP is very probable.3-CD4 cell count below 250 x mm3 argues for a necessary primary PCP prophylaxis in HIV seropositive patients.PCP occurs only in patients with CD4 count below 250 x mm3 and total lymphocyte count below 900 x mm3.(95.5% of cases in our series)

"Elevation of lactate dehydrogenase in asymptomatic AIDS patients"

Plasma of 115 anti-HIV positive patients without clinical symptoms was analyzed for lactate dehydrogenase (LD), its isoenzymes (LDI) and beta-glucuronidase. Total LD was elevated in 73% of these patients, the median value was 233 U/l (normal population: median 154 U/l, 97.5 percentile at 200 U/l). The underlying isoenzyme pattern most frequently showed elevation of LDI II (in 78%) and LDI III (in 82%). As pneumocystis-pneumonia could be excluded as cause, this pattern is highly suspicious for origin of the elevated LD in the lymphatic system. Patients were further subgrouped according to T 4 cell counts. Despite no correlation was found, it might be speculated that LDI II and III levels reflect the destruction rate of lymphocytes. This is supported by our observation, that total LD and LDI II and III are more frequently elevated in patients with positive HIV-antigen test. Roughly 40% of the patients show elevation of LDI V and IV and beta-glucuronidase as consequence of liver affection as verified by elevated transaminases.

In contrast to other reports it can be stated, that elevation of plasma lactate dehydrogenase with prominent isoenzymes II and III is a frequent phenomenon in anti-HIV positive patients without pneumocystis-pneumonia. This might reflect the disease activity in the lymphatic system.

M.B.P.107 ADENOSINE DEAMINASE (ADA) LEVELS IN SERA OF PATIENTS WITH HIV-1 INFECTION.

Valls, V.,Ena,Javier, Figueredo, I., Roca,V.,and De Salamanca, R.E..Department of Medicine, Hospital Clinico San Carlos, Madrid, Spain.

Objective. To assess the value of serum ADA quantification as a predictor of active M.tuberculosis (Tb.) infection and degree of immunosuppression in HIV-1 seropositive patients.
Methods. We quantified serum ADA levels in 38 HIV-1 seropositive (HIV+) patients: 9 with proven Tb. infection (Gr.I), and 29 without Tb. infection (Gr.II). Control groups consisted of 11 HIV-1 seronegative (HIV-) patients with proven Tb. infection (Gr.III) and 40 healthy HIV- volunteers (Gr.IV).
Results. ANOVA analysis showed that serum ADA levels were significantly elevated ($p < 0.01$) in Gr.I (48.39 ± 22.26 U/L), Gr.II (35.74 ± 16.4 U/L),and Gr.III (24.54 ± 11.82 U/L) when compared to Gr.IV (8.6 ± 4.6 U/L). ADA levels were statistically different ($p < 0.01$) in HIV+ (Gr.I & Gr.II) compared to HIV-(Gr.III & Gr. IV) patients.No statistical difference in ADA levels could be demonstrated between Gr.I and Gr.II. In the HIV+ patients we were unable to demonstrate any correlation between ADA levels and CD4+ cell count, active Tb infection or opportunistic infections.Of HIV+ patients, those belonging to WR5 stage showed the significantly higher levels of ADA. Using a backward logistic regression analysis we found that ADA serum levels were correlated with peripheral leucocyte counts ($p=0.0001$), peripheral monocytes counts ($p=0.0001$), IgM levels ($p=0.0019$) HIV-1 antigenemia ($p= 0.05$) (MR=0.82, ADJR=0.79, P=0.001).
Conclusion. Quantification of ADA serum levels in HIV- were useful for the presumptive diagnosis of Tb.infection, however in HIV+, ADA levels were not useful predictors of degree of immunosuppression or of active Tb infection.

M.B.P.104 THE EFFICACY OF SCREENING TESTS FOR INFECTIOUS DISEASES IN PERSONS WITH SYMPTOMATIC ARC

Gordin, Fred, Hartigan PM, Oster C, and the
VA Cooperative Study Group on the Treatment of ARC.
VA Medical Center, Washington, D.C., U.S.A.

Objective. To evaluate the efficacy of screening tests for secondary infections in patients entered in a multi-center study of zidovudine for ARC.
Method. Entry criteria for this study required patients to have T4 counts between 200-500, and symptoms of ARC such as fever, sweats, weight loss, fatigue, lymphadenopathy, or thrush. Baseline screening to identify active infections included a chest x-ray (CXR), serologies for syphilis, hepatitis B (HB), cryptococcus, a urine culture for cytomegalovirus (CMV), and blood cultures for CMV, fungus, and mycobacteria.
Results. Of 205 patients enrolled, 99% are male, 69% white, and the mean age is 40. HIV risk factors include 61% homosexual, 18% IV drugs, 9% mixed, and 12% other. Mean baseline T4 cell count was 340. Significant lymphadenopathy is present in 36%. ARC has been present over 6 months in 58%; systemic symptoms at screening in 55%. Tests completed to date: CXR abnormal in 19/191 (10%). Reactive serologies for syphilis 29/187 (16%), HB surface antigen 19/169 (11%), and cryptococcus 0/156. CMV urine positive in 3/86. Blood cultures complete to date for CMV (88), fungus (92), and mycobacteria (87) have all been negative.
Conclusion. In a population of symptomatic ARC patients with depressed T4 cells, routine screening for infectious agents may be of limited value. CXR, and syphilis and HB serologies appear warranted, however more expensive tests should await specific indications.

M.B.P.106 67 GALLIUM SCINTIGRAPHY OF CHEST IN AIDS PATIENTS. ANALYSIS OF 152 CASES.

Narciso P.*; Pau F.M.*; Pigorini F.*; Rosci M.A.*; Sette P.*; Visco Giuseppe* U.S.L. RM/10 "L. Spallanzani" Hosp..Dept. Infectious Diseases*A/°C. Forlanini° Hosp..Dept. Nuclear Medicine°, Rome, Italy.

OBJECTIVE.To evaluate the importance of chest 67 Ga scintigraphy in diagnosis of pulmonary diseases in AIDS patients, with negative or dubious XR findings.
METHODS. In the last two years 152 AIDS patients showing symptoms of lung diseases were studied with Ga scan; in 95 subjects diagnosis was performed after sputum culture, BAL, bacteriological and histological examination. An imaging of transmission scan obtained with planar source of 57 Co (10 mli, 370 MBQ) was used. Scan was classified as negative if lung/background ratio was 1,5; as positive + if 1,5 2; ++ if 2 2,5; +++ if 2,5 3; ++++ if 3.

RESULTS.	CASES N.	SCAN GRADE	0	+	++	+++	++++
P C P	34		2	7	2	16	7
C M V	11		-	5	3	2	1
C M V and other...	6		-	3	1	2	-
FUNGI.............	5		-	-	3	-	-
MILIARY TB........	6		-	1	1	3	1
OTHER.............	7		-	4	3	-	-

CONCLUSION. 1) High diffuse pulmonary concentrations of 67 Ga in AIDS patients seems to be related to an increased probability of PCP above all in chest X ray negative or dubious cases;2)low or negative Ga uptake in localized or extended pulmonary diseases indicates an increased probability of KS;3)In pulmonary TB 67 Ga scintigraphy allows a more accurate diagnosis of illness extent and activity.

M.B.P.108 CLINICAL MANIFESTATIONS OF AIDS IN WOMEN FROM SAO PAULO, BRAZIL

Ferreira,A.C.[1,2];Grandi,J.L.;[1] Fernandes,M.E.[1]
1,Paulista School of Medicine,Infectious Diseases Unit;
2,Reference Center for Aids,Sao Paulo,Brazil.

Objetive. To detect the most common clinical presentation, mortality rate and"cause mortis" of women with Aids.
Methods. We studied a sample of 55 women that had clinical manifestations of Aids and were treated in those two institution above,during the period of january 85 to january 89.
Results. Those 55 women with Aids correspond 22% of the Aids case in women from Sao Paulo State.The mortality rate was 22%.
Table 1. Most common Clinical Presentation

	Pneumonia(indet.)	Candidiase	Tuberc.	Sifilis	Oth
number Ocurr	25	19	5	3	6
%	44	33	8	5	10

Conclusion. The clinical presentation of Aids in women will be discussed in this study.

M.B.P.109 OPPORTUNISTIC INFECTIONS IN AIDS PATIENTS - A COMPARISON OF CLINICAL AND POSTMORTEM FINDINGS IN RIO DE JANEIRO, BRAZIL.

Ismael, Carla; Signorini, D.J.M.; OLIVEIRA, D.P.; Lacerda, M.C.R.; Basílio de Oliveira, C.A. and Morais de Sá, C.A.
Gaffrée & Guinle University Hospital - University of Rio de Janeiro (UNI-RIO) - Brazil.

Objective: To study the clinical diagnosis of opportunistic infections in our AIDS patients and compare to autopsy findings.
Methods: The study comprised 235 AIDS patients according to CDC criteria from Dec 1984 to Dec 1988. Clinical diagnosis of opportunistic infections was based on microscopic identification, gross appearance, serology, cultures, radiologic studies, physical examination and response to treatment. 27 autopsies were performed from this group of AIDS patients.
Results: Opportunistic infections were observed as follows:

INFECTOUS AGENTS	CLINICAL DIAGNOSIS (N=235)	%	POSTMORTEM DIAGNOSIS (N=27)	%
Candida albicans	156	66,4	5	18,5
Mycobacterium tuberculosis	84	35,7	10	37
Toxoplasma gondii	55	23,4	9	33,3
Pneumocystis carinii	43	18,2	1	3,7
Cryptosporidium sp	38	16,1	6	22,2
Cytomegalovirus	14	5,9	10	40,7
HBV	9	3,8	8	29,6

Conclusions: 1) Cerebral toxoplasmosis and tuberculosis are frequent findings both clinically and at necropsy studies, being a common cause of death. 2) Candidiasis is a frequent clinical diagnosis but not as common as a postmortem finding, probably due to a good response to anti-fungal drugs. 3) Disseminated cytomegalovirus with visceral involvement was the most common necropsy finding but was not so obviousclinically. 4) Pneumocystis carinii and Cryptosporidium were more frequently identified on clinical diagnosis whereas HBV was more frequently identified in postmortem findings.

M.B.P.110 A SEROLOGIC STUDY OF CRYPTOSPORIDIUM INFECTION IN HIV POSITIVE MEN AND THE RELATIONSHIP TO T-CELL SUBSETS

Leach, Charles*; Kuhls, T.**; Mosier, D.***; English, P.****; Giorgi, J.*; Cherry, J.*; et al.
UCLA Sch. of *Medicine and ****Public Health, Los Angeles, California, USA; **Univ. of Oklahoma Health Sciences Center and ***Oklahoma State University, Oklahoma City, Oklahoma, USA.

Objective. To determine the prevalence of antibody to Cryptosporidium (Crypto Ab) in HIV infected men and investigate its association with T-cell subsets.
Methods. As part of the Multicenter AIDS Cohort Study (MACS) in Los Angeles blood was collected from 237 asymptomatic HIV seropositive homosexual men. Crypto Ab was measured by an ELISA technique using purified sonicated oocysts from a bovine source.
Results. The prevalence of Crypto Ab was 83% in the study cohort whereas the prevalence was 50-60% in adult controls. Antibody concentrations varied between 1 and 66 ELISA units/ml(EU) with a mean + SD of 17.6 + 11.5 EU. Neither the presence of Crypto Ab nor its concentration was associated with CD-4, or CD-8 counts or CD-4/CD-8 ratios.
Conclusion. Asymptomatic HIV infected men have a high prevalence of Cryptosporidium antibody. Using cross-sectional data only, there is no evidence that Crypto Ab positivity or concentration is related to T-cell subset values. Analysis of prospective data is underway.

M.B.P.111 CD4+-T-LYMPHOCYTES AND THE MANIFESTATION OF OPPORTUNISTIC MUCOCUTANEOUS INFECTIONS IN HIV-INFECTION

Schoefer, Helmut; Ochsendorf, FR. and Milbradt, R.
Klinikum der J.W.Goethe Universität, Dept.of Dermatology, Frankfurt, FRG.

Objective. Evaluation of opportunistic mucocutaneous infections (OI_{MC}) as diagnostic parameters for HIV-infection.
Methods. In a 4 years clinical trial 267 HIV-infected patients were investigated for infectious dermatological diseases by viral, bacterial and fungal agents. 84% were male homosexuals, 8,6% IVDA and 1% patients with hemophilia. Dermatological investigations were repeated 1-18x (mean: 4x) and T-lymphocyte subsets were drawn at the time of OI_{MC} diagnosis.
Results.

Patients	total	AIDS	ARC	LAS	SLS	CD4+/µl	clas-
(n=)	267	87	76	86	18	(mean	sifi-
	%	%	%	%	%	value)	cation
1.oral candidiasis	44	61	43	34	11	249	II
2.folliculitis	31	18	37	41	17	414	III
3.herpes-exulc.	21	33	17	15	-	319	I
4.genital warts	18	13	22	20	17	408	III
5.herpes zoster	16	18	20	13	-	352	II
6.warts	16	9	24	17	6	380	III
7.hairy leukopl.	10	11	13	8	-	315	I
8.mollusca cont.	8	16	7	2	-	346	II
9.bact. abscesses	7	6	9	8	-	312	III

Conclusions. OI_{MC} are frequent and of diagnostic value in HIV-infection: Class I OI_{MC} (almost pathognomonic for immunodeficiency;id.): Herpes exulcerans and hairy leukoplakia. Class II OI_{MC} (important indicators of id.): oral candidiasis, herpes zoster and mollusca contagiosa. Class III OI_{MC} (less important indicators of id.): all other mentioned OI_{MC}.

M.B.P.112 PREVALENCE OF HEPATITIS B AND DELTA VIRUS INFECTION IN HEMOPHILIACS WITH AIDS

BRANDÃO-MELLO,C.E.* ; GONZAGA,A.L.* ; SIMONETTI,J.P.** & SIMONETTI,S.R.R.**
* CENTRO DE HEMATOLOGIA SANTA CATARINA - RIO DE JANEIRO,BRASIL.
** FUNDAÇÃO OSWALDO CRUZ - DEPARTAMENTO DE VIROLOGIA - RIO DE JANEIRO,BRASIL.

The evaluation of the prevalence of HBV and HDV infection in hemophiliacs with AIDS and in asymptomatic patients(control) was the aim of this work.
Methods: We have evaluated the prevalence of HBV and HDV infection in 2 distinct groups: 1)immunodeficient hemophiliacs(hem.): AIDS (n=14);ARC(n=34);2)asymptomatic hem.(n=41). All these patients were severe hem.,being 41 A and 7 B in the first and 37 A and 4 B in the second group, respectively.They were exclusively transfused with local factor VIII or IX concentrates supplied by voluntary donors. We studied HBV serum markers by commercial RIA kits for the detection of HBsAg,Anti-HBs,Anti-HBc,HBeAg & Anti-HBe. Anti-Delta was studied by blocking enzime-immunoassay(Elisa).
Results: The cumulative HBV infection index(HBsAg,Anti-HBs and Anti-HBc) was 100% in the first group and 86,8% in the second one. There was no statistically significant diference. HBsAg was a little more positive in the first(16.6%) in comparison with the second group (8.4%).Anti-Delta was found in none .
Conclusions: 1.The small difference in the prevalence of HBV infection in the first and the second group confirms that hemophiliacs are high risk group for HBV infection, most of them displaying Anti-HBs & Anti-HBc.
2. The frequent finding of HBsAg in the immunodeficient group in comparison with the control group can be probably explained by the fact that the former is at increased risk of developing the chronic HBsAg carrier state.

M.B.P.113 CHRONIC ACTIVE HEPATITIS (CAH) IN TWO GROUPS OF IVDAs (HBcAb positive) WITH AND WITHOUT HIV INFECTION.

Fedeli F.*, Gardini G.*, Gafà S.**, Giudici M.G.**, Tumma A.**, Migrioli E.*
*Surgical Phatology Dept.,**Infectious Dis. Dept., Arcispedale S.Maria Nuova, Reggio Emilia, Italy.

Objective:a purpose of this study is the clinical-pathological evaluation of two IVDA groups (HBcAb positive) with and without HIV infection.
Methods: liver biopsy of 13 IVDA patients with HIV infection belonging to the IInd and IIIth group of CDC classification was studied and HBcAg was researched in paraffin section with PAP method. These datas were comparated with liver biopsy of other 9 IVDA patients without HIV infection.
All the patients were admitted hospital for CAH and they were positive for HBcAb in sera.
Results: morphological and immunohistochemical studies showed no difference between the two groups. HBcAg was detected only in one patient in each group. We suppose that the lack of difference between the two groups is due to the mild immunodeficiency of HIV infected patients belonging the IInd and IIIth group of CDC classification.
Conclusion: In IVDA patients of two groups of ours HBcAb positive, we suspect that Chronic Active Hepatitis is supported by other viruses than HBV.

CMV
CMV

M.B.P.114 HUMAN CYTOMEGALOVIRUS ANTIGENEMIA FOR MONITORING SISTEMIC INFECTIONS AND GANCICLOVIR TREATMENT IN AIDS PATIENTS

Revello M.G., Percivalle E., Zavattoni M., Grossi P., Minoli Lorenzo, Gerna G.
Inst. Infect. Dis. Univ. of Pavia, IRCCS Pol. S. Matteo, 27100 Pavia, Italy.

Objective. To correlate human cytomegalovirus (HCMV) antigenemia and viremia as parameters for monitoring sistemic HCMV infections and the antiviral effect of ganciclovir treatment in AIDS patients.
Methods. Virological follow-up of HCMV infections included monitoring of: i) antigenemia in peripheral blood polymorphonuclear (PMN) cells by immunofluorescence (IFA) using a MAb to immediate early antigens (1-2 h assay); ii) viremia, following inoculation of PMN cells onto fibroblasts and IFA staining of cell cultures 24-48 h p.i. with a MAb to early antigens.
Results. So far, results obtained on sequential blood samples collected from 9 AIDS patients with sistemic HCMV infections showed 83% (19/23) correlation between antigenemia and viremia. In 4 cases a dissociation between positive antigenemia and negative viremia was observed. Discrepant results were found in blood samples collected during ganciclovir treatment. Discontinuation of antiviral chemotherapy was followed by reappearance of viremia, while antigenemia was persisting.
Conclusion. HCMV antigenemia and viremia are highly correlated; however, both should be determined during ganciclovir therapy to establish virus clearance from blood. (Partially supported by Min. Sanità, Progetto AIDS 1987/88).

M.B.P.115 THE SIGNIFICANCE OF DETECTING CYTOMEGALOVIRUS IN BRONCHOALVEOLAR LAVAGE SAMPLES FROM AIDS PATIENTS WITH RESPIRATORY DISEASE

Barton, S.E.; Hawkins, D.A.; Gazzard, B.G.
Kobler Centre, St. Stephen's Hospital, Fulham Road, London SW10 9TH, UK.

Objective. To assess the prognostic significance of the detection of early antigen fluorescent foci (DEAFF) of cytaregalovirus (CMV) in the bronchoalveolar lavage (BAL) fluid of AIDS patients with acute respiratory illnesses.
Mehtods. All AIDS patients with pneumonia who underwent diagnostic bronchoscopy were reviewed. Patients were divided into three groups; those with CMV infection, those with PCP and those with dual pulmonary infection. The subsequent morbidity and mortality of these patients and the effects of using phosphonoformate or ganciclovir as anti-CMV therapy were examined. A study of the significance of detecting CMV by DEAFF testing in urine, blood and throat washings was performed.
Results. This study found that the administration of anti-CMV therapy to AIDS patients with or without concurrent PCP had no significant effect on their immediate or long term survival rates. Moreover, treatment of the index CMV infection had no effect on the low rates of subsequent episodes of CMV colitis or retinitis. A significant ($p<0.05$) association was detected between the finding of positive DEAFF tests for CMV in additional non-pulmonary sites and a worse prognosis in those patients.
Conclusion. The results demonstrate that therapy for CMV infected BAL specimens does not improve the survival nor reduce the recurrent CMV infection rates. The detection of CMV at multiple sites is a poor prognostic indicator of survival in AIDS patients.

M.B.P.116 CYTOMEGALOVIRUS COLITIS IN AIDS: PRESENTATION IN 33 PATIENTS.

Dieterich, Douglas; Rahmin, M.; Rotterdam, H.; Dolinsky, D.; New York University Medical Center, New York, New York, U.S.A.

OBJECTIVE. To describe the clinical characteristics of CMV colitis at presentation. METHODS. A double blind placebo controlled study of the treatment of CMV colitis with ganciclovir in AIDS patients is ongoing. A report of the characteristics of the first 33 cases is presented. A scale of grading colitis, CMV inclusion bodies and inflammatory response from 0-3 was developed to quantitatively assess CMV colitis. RESULTS. All patients were homosexual men with a median age at AIDS diagnosis of 43.4 yrs. (mean 41.5), had CMV on colonic biopsy and no other enteric pathogen. 9/33 (27%) had CMV colitis as their index diagnosis for AIDS. 24/33 (73%) had persistent diarrhea, 8/33 (24%) had intermittent diarrhea, and 1/33 presented with a lower GI bleed. 28/33 (85%) were febrile, median 102° (mean 101.9°). 29/33 (88%) reported weight loss, median 15 lbs. (mean 20 lbs.). Patients with diarrhea averaged 7.2 liquid stools per day. 13/33 (39%) reported hematochezia. 22/33 (67%) had cramping abdominal pain. The median duration of AIDS diagnosis in patients without CMV as an index diagnosis was 11.18 mos. (mean 11.34). The median time between onset of diarrhea and CMV diagnosis was 1.63 mos. (mean 2.17). 16/33 (48%) patients received AZT prior to diagnosis. There was a trend of prolonged time to CMV colitis in patients receiving AZT. 28/33 (85%) had other opportunistic infections. 15/33 (45%) had other CMV disease concurrently. 9/33 (21%) had bronchoscopy with TBB and BAL, 4/9 (44%) was + CMV; 7/33 (21%) had a liver biopsy, 0/7 (0%) was + CMV; 10/33 (30%) had upper endoscopy, 1/10 (10%) was + CMV. Median survival after enrollment is 8.06 mos. (mean 11.01). LABS: Hgb median 10.9 (mean 10.75). WBC median 3.2 (mean 3.78). Ca^{++} median 8.4 (mean 8.0). Total Protein median 6.3 (mean 6.36). Albumin median 3.3 (mean 3.3). 17/33 (52%) had Alkaline Phosphatase > 100 (nl 30-100). 22/33 (67%) had a + CMV urine culture. 11/33 (33%) had a + CMV blood culture. 27/33 (82%) had either urine or blood cultures + CMV. Colonoscopic grade of colitis (0-3) was median 2.0 (mean 2.1). Inflammation grade of biopsy specimen (0-3) was median 1.8 (mean 1.7). CMV grade of biopsy specimen (0-3) was median 1.0 (mean 1.68). CONCLUSIONS. 1) CMV colitis presents relatively early in AIDS and is a significant index diagnosis. 2) Non-specific signs such as fever, diarrhea, weight loss, hematochezia, and anemia in the absence of other GI pathogens should lead to colonoscopy and biopsy for early diagnosis of CMV. 3) AZT therapy may delay the onset of CMV colitis. 4) Patients with CMV colitis are likely to have multiple opportunistic infections in multiple organ systems. 5) Colonoscopic findings of CMV colitis did not correlate with the number of CMV inclusions seen. 6) When 60 patients are enrolled the code will be broken and the data will be analyzed for the effect of ganciclovir on CMV colitis.

M.B.P.117 PROPHYLAXIS OF CMV RETINITIS RELAPSE : EVALUATION OF FOSCARNET IN MAINTENANCE THERAPY

Christine Katlama*, E. Dohin, I. Massin-Cochereau**, D. Fassin*, P. Le Hoang**, M. Gentilini*
Department of Parasitology & Infectious Diseases* & Department of Ophtalmology**, Hôpital Pitié-Salpêtrière. Paris. FRANCE.

Objetive. Evaluation of efficacy and tolerance of Foscarnet (PFA) in preventing relapses of CMV retinitis.
Methods. 48 courses were given in maintenance therapy (MT) to 22 AIDS patients who successfully completed PFA induction therapy with residual scarring lesions. They were started with 60mg/kg/d-5days/week (MT1) in 11 cases and with 100mg/kg/d-6d/week in 10 cases (MT2) ; subsequent courses were given successively through 130mg/kg/d in one infusion (MT3) in 19 cases then, if needed, in 60 mgx2/d infusions (MT4) 7 days/week.
Results. Prevention of relapse was obtained : in 9% (1/11) with MT1 - follow up (FU): 40 weeks ; in 50% (5/10) with MT2 - mean FU:24 weeks; in 30% (6/19) with MT3 - mean FU: 22 weeks and 9% (1/8) with MT4 - FU: 15 weeks. Relapses occured in 90% (10/11) in MT1- mean delay (md):28 days; in 50% with MT2 - md:41 days ; in 70% (14/20) in MT3 - md:42 days and in 87% (7/8) in MT4 - md:24 days. Side effects were : mild renal insufficiency in 2/48 (4%), digestive intolerance in 6/22 (27%).
Conclusion. Foscarnet appears to be effective on preventing CMV retinitis relapse with high and frequent administration. Because of its excellent tolerance, particularly hematologic, Foscarnet is a promising drug to be investigated further on for an adequate prophylaxis of CMV retinitis.

M.B.P.118 CMV MENINGOENCEPHALOMYELITIS A.I.D.S.: A CASE REPORT

Ennio Ricchi*, P.Costigliola*, A.Casadei*, F.Biangasparo**, F.Chiodo*
*Istituto Malattie Infettive - **Istituto Anatomia Patologica - Universita' di Bologna, Bologna , ITALY

Objective. We report on a case of a sudden onset of CMV meningoencephalomyelitis with rapid fatal outcome in an A.I.D.S. patient.
Case report. A PCP diagnosed A.I.D.S. patient was admitted to hospital on account to onset of fever, diarrhea, paraesthesia and hyposthenia to inferior limbs. During the admission abdominal pains, paralytic ileus and incontinence suddenly occurred. Clouding, sopor and convulsions followed but no signs of meningism were seen. CAT scanning of the brain showed only mild atrophy of frontal and parietal lobes. Liquor examination didn't denote any mark of bacterial or viral infection, and cultures (for viruses and bacteria) were negative. Coma ad exitus occurred 48 hours after the onset of neurological symptoms. Postmortem examination didn't reveal macroscopic alterations to the brain, but spinal cord appeared to be intumescent in its thoracic and lumbar tracts. On section the gray seemed to be disappeared in these tracts and the parenchyma looked homogeneous and whitish. Histological examination showed a great spread of CMV infection judged by the presence of cells with characteristic intranuclear and cytoplasmic inclusions in both hemispheres and cerebellum. Necrosis zones appeared in thoracic and lumbar tracts of spinal cord; they were found instead of gray as cells with viral inclusions. A conspicuous demyelinization of roots of lumbar spinal nerves was also seen.
Conclusion. We underline the possibility that fatal CMV infection of CNS and PNS may occur in A.I.D.S. patients in absence of foreshowing clinical signs.

M.B.P.119 TREATMENT OF CMV RETINITIS IN AIDS : EXPERIENCE WITH 59 COURSES OF FOSCARNET (PFA).

Christine Katlama*, E. Dohin*, B. Girard**, G. Brücker*, M. Rosenheim*, P. Le Hoang**, M. Gentilini*.
Departement of Infection Diseases* & Ophtalmology**, Hôpital Pitié - Salpêtrière, Paris, FRANCE.

Objective. Evaluation of efficacy and tolerance of Foscarnet in induction therapy (IT) of acute CMV retinitis.
Methods. 59 courses of PFA were administered to 26 AIDS patients with newly diagnosed CMV retinitis (n=26) or relapse (n=33) ; PFA (200 mg/kg/day) had been given intraveinously through continuous infusion in 29 cases and as an intermittent 2-hour infusion repeated q-8 hours in 30 cases, for 3 of 4 weeks ; hydratation with 1 500cc serum saline isotonic was associated.
Results. The overall rate of successful therapy was 57/59 (96%) with a complete resolution of lesions in 26/26 during the first IT and 31/33 in subsequent ones. Mean duration of therapy was 27 days (14d → 43d). 2/59 had progression of lesions while on a third IT.16/38 CMV viremia were positive (CMV ⊕) at study entry ; 13 became negative, 3 remained positive, and 1 became positive. In all 4 courses with CMV ⊕ at end of IT, delay of relapse was very short (7 days to 21 days). PFA side effects were minor and unfrequent : renal insufficiencyin 9/59 (15%)(maximum creatininemia 252 µmol/l) ; no hematologic and digestive intolerance was noted.
Conclusion. Foscarnet appears highly effective on acute CMV retinitis with complete resolution and residual scarring in 96% of cases ; tolerance was good with mild reversible renal insufficiency in 15%. The absence of transcient hematoxicity appears helpful in AIDS patients especially when zidovudine is associated.

M.B.P.120 GANCICLOVIR-THERAPY IN GASTROINTESTINAL CYTOMEGALOVIRUS LESIONS IN AIDS

Heise,Walter,Mostertz,P.,Arasteh,K.,Grosse,G.,Timm,H.,L'age,M.
Auguste-Viktoria-Hospital, Robert-Koch-Institut, Internal Medicine, Depts. of Pathology and Virology, Berlin, Federal Republic of Germany.

Objective: Gastrointestinal (GI) Cytomegalovirus (CMV) lesions were found in one third(54/158) of all AIDS patients with GI symptoms.25/54 patients were treated with Ganciclovir, 5 mg/kg twice daily,three weeks. Clinical, virological and histological response,healing of the mucosal lesions and possible side effects were monitored.
Methods: A diagnose of GI manifestation due to CMV was based on endoscopic examination,CMV inclusions in tissue obtained by biopsy,immunhistological studies and positive cultures.Side effects were checked by laboratory data and clinical symptoms.
Results: 2o/25 (8o%) patients had severe tissue lesions.Complications like penetration or bleeding occured in 5/25 cases.A good clinical response was observed in 21/25 patients,healing of the ulcerations in 19/25 and histological response in 18/25. CMV-cultures turned negative just in 9/25 patients indicating persistence of the infection.Severe side effects were not observed.Mild leucopenia occured in 9/25 patients which was not considered to interrupt therapy.
Conclusions: Ganciclovir had good clinical and histological efficacy in CMV lesions in GI tract in 2o/25(8o%) of symptomatic patients with an impressing healing of endoscopically documented and controlled GI lesions. Side effects and laboratory abnormalities were reported in few cases. Hematological side effects could be a problem of maintenance therapy.

M.B.P.121 GANCICLOVIR THERAPY FOR CYTOMEGALOVIRUS RELATED POLYRADICULO(MYELO)PATHY IN PATIENTS WITH AIDS.

De Gans, Jan*; Tiessens, G.**; Portegies, P.*; Troost, D.* and Danner, S.A.*. *Academisch Medisch Centrum, 1105 AZ Amsterdam, **Vereeniging voor Ziekenverpleging, Amsterdam, The Netherlands.

Objective. To assess the efficacy of ganciclovir therapy in AIDS patients with cytomegalovirus (CMV) related polyradiculo(myelo)pathy.
Methods. Four adult homosexual HIV-1 seropositive patients with CMV related polyradiculo(myelo)pathy and severe flaccid paraparesis were studied. All patients had disseminated CMV infection. The following diagnostic studies were performed: 1. myelography; 2. CSF examination with viral cultures; 3. electromyography and nerve conduction studies in three patients; 4. immunohistochemistry and in situ hybridization on CSF and autopsy specimens. Three patients received induction treatment with ganciclovir, 2.5-5 mg/kg intravenously every 12 hours for two or three weeks. This was followed by maintenance therapy, 5 mg/kg/day, five days per week in two patients. One patient already received ganciclovir therapy for CMV retinitis and colitis, which was continued and later replaced by foscarnet. Autopsy was performed in two patients.
Results. Myelography showed arachnoiditis of the lumbar nerve roots in two patients and was normal in the other two. CSF VDRL was negative and bacterial, fungal and mycobacterial cultures were sterile. CMV was cultured from CSF in two patients. CSF cytology showed large cells containing basophilic intranuclear inclusions and a huge amount of fine granular basophilic cytoplasm. CMV nucleic acids were detected in all CSF and autopsy specimens. Three patients who were initially treated with ganciclovir showed no evident neurological improvement. One patient who developed polyradiculo-(myelo)pathy while receiving ganciclovir did not improve after ganciclovir was replaced by foscarnet.
Conclusion. Ganciclovir therapy was unsuccessful in four AIDS patients with CMV polyradiculo(myelo)pathy. Perhaps early ganciclovir therapy, possibly higher dosed or combined with other antiviral agents can prevent progression of CMV polyradiculo(myelo)pathy.

M.B.P.122 AN OPEN COMPARITIVE STUDY OF FOSCARNET AND GANCICLOVIR IN THE TREATMENT OF CMV RETINITIS

Newell, Mark; Harris, M.; Moyle, G.; Smith, D.; Clarbour, J. and Gazzard, B. St. Stephen's Hospital, Chelsea, London SW10 9TH England.

Objective To compare the efficacy and safety of foscarnet (F.) and ganciclovir (G.) in the treatment of CMV retinitis.
Methods Fourteen patients over 6 months with CMV retinitis were given either a 3 week induction course of G. (5mg/kg/b.d. I.V.-6 patients) or F. (approx 200mg/kg/d. I.V.-8 patients) followed by maintenance therapy 5 days a week (F. 130mg/kg/d., G. 5mg/kg/d. I.V.). Ophthalmological response and any adverse reactions were monitored.
Results A. Acute treatment All 6 patients on G. completed the course uninterrupted without adverse effect and showed some visual improvement. Five out of 8 patients on F. also completed the course uninterrupted but in 2 a rise in serum creatinine resulted in a dose reduction or interruption. Five patients showed some visual improvement but 3 had continuing active disease one of which was switched to G. B. Maintenance Six patients on each drug, average duration for F. 11 weeks (range 2 - 19 weeks), for G. 14 weeks (range 4 - 26 weeks). Five patients on F. developed a raised creatinine resulting in dose cessation(1), reduction(1) or interruption(2). In only 1 has disease remained quiescent and 4 patients have died. Three of 6 patients on maintenance G. required dose reduction(1), interruption(1) and change to F.(1) due to neutropenia. Four patients had stable disease, one had a retinal detachment and one relapse requiring dose increase.
Conclusion F. and G. have similar efficacy in the treatment of CMV retinitis but F. showed greater toxicity and may be less effective for maintenance.

M.B.P.123 TOLERANCE AND EFFICACY OF DAILY INTRAVENOUS (IV) MAINTENANCE FOSCARNET (PFA) THERAPY FOR CYTOMEGALOVIRUS (CMV) RETINITIS IN AIDS PATIENTS (ACTG PROTOCOL 015).

Jacobson, Mark A*, Causey, D**, Hardy, D***, Polsky, B****, Mills, J*, Feinberg, JE*****, et al. *UCSF and S.F. General Hospital, San Francisco, CA; **LAC-USC Med Center, Los Angeles CA; ***UCLA Center for the Health Sciences, Los Angeles, CA; ****Memorial Sloan Kettering Cancer Center, New York, NY; *****AIDS Clinical Trial Group, NIAID, Bethesda, MD, USA.

Objective. Determine tolerance and efficacy of escalating doses of daily IV maintenance PFA therapy (Rx).
Methods. We treated 29 patients (pts) with AIDS and newly diagnosed CMV retinitis with induction IV PFA, 60 mg/kg q 8 hr. 24/25 pts who completed 14 day induction Rx had retinitis stabilize (no new retinal lesions and stable old lesions). After PFA induction, 16 pts continued maintenance PFA therapy (Rx), 60 mg/kg/day. 10 pts had new retinal lesions or old lesions increase in size after 2-24 wks of maintenance Rx, and 6 pts remained stable after 8-28 wks. Median time to retinitis progression on maintenance Rx was in the range of 6-20 wks. During maintenance PFA Rx, 3/16 (19%) pts had PFA discontinued because of probable drug toxicity (azotemia [2], fever [1]). No pts developed severe neutropenia with PFA Rx. We will also present preliminary tolerance and efficacy data from a continuation of this trial in which 28 new CMV retinitis patients are being randomized to receive maintenance PFA Rx at either 90 mg/kg/day or 120 mg/kg/day following induction PFA Rx.
Conclusion. Efficacy of long-term PFA maintenance Rx, 60 mg/kg/d, for CMV retinitis appears similar to that reported for long-term ganciclovir Rx. Dose-limiting neutropenia was not observed with chronic PFA Rx.

M.B.P.124 CYTOMEGALOVIRUS CULTURES DURING MAINTENANCE DHPG THERAPY FOR CMV RETINITIS IN AIDS.

Jennens,I.D.; Lucas,C.R.; Sandland,A.M.; Hoy,Jennifer; Maclean,H.; and Hayes,K..
Fairfield Infectious Diseases Hospital, Melbourne, Victoria, Australia.

Objective. To determine the effect of high and low dose DHPG maintenance therapy on the prevalence of CMV isolation in patients with stable or progressive CMV retinitis.
Methods. Blood, urine and saliva samples were collected 1-2 weekly and cultured for CMV from 9 male homosexual AIDS patients who received >1 month (range 1.5-12) of maintenance DHPG for CMV retinitis. Patients were assessed by indirect fundoscopy as having stable or progressive CMV retinitis.
Results. CMV isolation according to site of sample and dose of DHPG:

	Pre treatment	Maintenance DHPG (mg/kg/wk)	
		Low dose (15-25)	High dose (27-32)
Leucocytes	*11/70 (65%)	37/70 (53%)	9/98 (9%)
Urine	17/22 (77%)	20/71 (28%)	8/93 (8%)
Saliva	20/20 (100%)	33/70 (47%)	23/99 (23%)
Total	48/59 (81%)	#90/211 (43%)	#40/290 (14%)

*No. of samples positive/number tests (%) (# x^2 test, $p<0.001$).
Three patients with progressive retinitis had viremia more frequently than did 6 patients with stable retinitis, CMV being isolated from 29/47 (62%) and 17/121 (14%) of blood samples respectively (x^2, $p<0.001$).
Conclusion. Reduction in CMV viremia and viral shedding was greater using high dose than low dose maintenance therapy. Viremia on maintenance DHPG therapy may be useful in predicting patients at risk of progressive retinitis.

M.B.P.125 PULMONARY CMV INFECTION IN AIDS PATIENTS. A CLINICOPATHOLOGIC STUDY

Krystossek, Heinz*; Ruf, B.*; Jautzke, G.**; Timm, H.***; Pohle, H.D.*
* Departments of Internal Medicine and ** Pathology, Rudolf Virchow University Hospital (Wedding), Freie Universität Berlin, *** Robert Koch Institute, Federal Health Office, Berlin, FRG.

Objective. The clinical relevance of demonstration of CMV infection by culture or by serology is often uncertain. Clinical data and pulmonary autopsy findings from 58 AIDS patients were compared with regard to CMV infection.

Methods. Routine staining procedures, immunohistochemistry (APAAP) and culture. The results were compared with clinical data (serology, virus culture).

Results. CMV was detected in lung tissue in a total of 32 patients (55 %), in 17 cases both by culture and immunohistochemistry. In 10 cases only culture was positive, in five cases CMV was detected only by immunohistochemical examination. Only in 4/32 cases cells with inclusion bodies were found (HE stain); both additional methods (culture, APAAP) were positive for CMV. In 22/32 patients (69 %) anti-CMV serum antibodies (IgG) were found. In 11/32 cases (34 %) CMV was recoverd from clinical material. According to the typical histopathological patterns no evidence for CMV pneumonitis was found.

Conclusion. The majority of patients with AIDS have pneumonia, but CMV is rarely the causative agent.

M.B.P.126 POSSIBLE USEFULNESS OF HIGH DOSE ACYCLOVIR AS PROPHYLAXIS FOR CMV

Metroka, Craig E.; Josefberg, H.
St. Luke's/Roosevelt Hospital Center, New York, NY, USA.

Objective. An open study of the efficacy of high dose acyclovir in the prevention of invasive CMV.
Methods. We studied 60 patients (pts) who were at high risk for CMV, from 12/87 to 1/30/89. All pts had <150 T4+ cells/mm^3.
Results. The mean T4+ cells at the time of treatment initiation was 75 (range, 4 to 146). 30 pts also received AZT and dapsone, 16 pts received AZT and bactrim, 9 pts received AZT and aerosolized pentamidine, 3 pts received aerosolized pentamidine, and 2 pts received dapsone alone. The mean duration of follow-up was 6.25 mos (range up to 13 mos). During this time no pts receiving 800 mg of acyclovir q4h developed clinical, histological, or virological evidence of CMV. In contrast 3 of 9 pts who refused treatment developed evidence of invasive CMV. 3 pts treated with acyclovir died during the period of observation; none of these with evidence of CMV.
Conclusion. This study raises the possibility that acyclovir may be useful as prophylaxis for CMV. Further longitudinal studies will be necessary to determine the efficacy of this treatment.

M.B.P.127 DIAGNOSIS AND GRADING OF CMV COLITIS: COMPARISON OF H&E STAINS, DNA IN-SITU HYBRIDIZATION, AND IMMUNOPEROXIDASE STAINS FOR EARLY AND LATE ANTIGENS.

Heidrun Rotterdam, MD, Yi-Jin She, MD, D. Dieterich, MD NYU Medical Center, New York, NY.

The diagnosis (dx) of CMV colitis and grading of its severity have become important issues since specific treatment has become available. We compared the results of H&E stains, in-situ hybridization (isH), and immunoperoxidase stains for early and late CMV antigens (IPS) in order to determine the most accurate method for dx and grading. We examined 38 colon biopsies (bx) of 30 AIDS patients suspected of having CMV colitis. In 10 bx no CMV inclusion bodies (IB) were seen on H&E stains and both isH and IPS were negative. In 28 bx CMV IB were seen on H&E stains and all were positive either by both isH and IPS (21), only isH (2), or only IPS (6). The numbers of infected cells in a single bx varied from 1 to 221, IPS yielding the highest counts and H&E the lowest. The severity of infection was graded by relating the total number of infected cells to the number of bx pieces. Grade I was defined as 1-4, grade II as 5-9, and grade III as 10 or more infected cells per bx piece. Grades remained the same by all 3 techniques in 11 bx and varied in 17. Grades based on IPS were higher than those based on H&E or isH in 6 bx. Lowering of grades based on IPS or isH occurred in 11 cases, and was accompanied by a marked decrease of tissue left for these special procedures. We conclude that (1) a dx of CMV colitis based on the identification of CMV IB on H&E stained sections is accurate, (2) although IPS identifies the greatest numbers of infected cells, this gain in sensitivity is outweighed in endoscopic bx by the loss of tissue after cutting of levels, and therefore (3) grading is best performed on H&E stains.

M.B.P.129 THERAPY OF CYTOMEGALOVIRUS (CMV) INFECTIONS WITH GANCICLOVIR.

K. Rolston, S. Rodriguez, F. Carvajal, J. Nelson, G. Brewton, A. Rios, G. P. Bodey and P. Mansell.
University of Texas M. D. Anderson Cancer Center, Houston, Texas, U.S.A.

Objective - To evaluate the efficacy and safety of ganciclovir for the therapy of CMV infections in AIDS patients.
Methods - HIV infected patients with various CMV infections received ganciclovir (10 mg/kg/day x 14d). Response and toxicity were monitored.
Results - Forty-eight patients, 46 men, 2 women (median age 34) were treated. Sites of infection were retinitis - 34; colitis - 14; esophagogastritis - 2 (multiple sites in 2 pts.). Response rates were:

Response	Retinitis	Colitis	Esophagogastritis
Improved	9 (26%)	13 (93%)	2 (100%)
Stabilized	17 (50%)	-	
No change/worse	8 (24%)	1 (7%)	

Patients with retinitis who failed to respond (including 2 with retinal detachment) generally had a greater than 10 day delay in initiation of therapy. Two patients with colitis improved despite developing colonic perforation. One patient developed disseminated disease including adrenalitis. More than 50% of patients who responded received maintenance therapy with ganciclovir. Therapy was generally well tolerated, however 23% of patients developed neutropenia (PMN <1000/mm^3). Nausea and confusion were seen infrequently.
Conclusion - Ganciclovir is safe and effective in initial and maintenance therapy of CMV retinitis and gastroenteritis.

M.B.P.131 IN VITRO SECRETION OF CMV SPECIFIC ANTIBODIES BY PERIPHERAL BLOOD CELLS FROM HIV1 INFECTED SUBJECTS.

Vendrell, Jean-Pierre**; Segondy, M.*; Ducos, J.**; Reynes, J.***; Huguet, M.F.*, Cannat, A.* and Serre, A.**.
* INSERM U65, ** Laboratoire d'Immunologie, Hôpital Lapeyronie, *** Service Maladies Infectieuses, Hôpital St Eloi, MONTPELLIER, FRANCE.

INTRODUCTION. A permanent capacity for in vitro secretion of HIV1 antibodies by the circulating B cells of HIV1 infected subjects has been evidenced. Since CMV infection is very often associated with AIDS disease we wondered whether CMV specific B cells could also be evidenced in the blood stream of HIV1 seropositive subjects.
METHODS. Supernatants of overnight cultures of the PBMC from 57 HIV1 seropositive and 24 HIV1 seronegative subjects were incubated in wells from Behring or Pasteur CMV ELISA kits. In vitro antibody secretion was detected using a low noise amplifying enzymatic complex.
RESULTS. a) 50 positive, 5 negative and 2 intermediate CMV in vitro antibody production tests (IVAP) were observed with HIV1 positive PBMC and 2 positive, 20 negative and 2 intermediate with the 24 HIV1 negative controls. b) While all HIV1 seropositive were also HIV1-IVAP positive, all CMV seropositive subjects were not ipso facto CMV-IVAP positive. c) Preincubation of PBMC with CMV infected MCR5 cells specifically inhibits CMV and not HIV-IVAP. d) CMV-IVAP positivity was shown to be a transitory phenomenon in HIV negative and a persistant phenomenon in HIV1 positive subjects.
CONCLUSIONS. The detection of CMV antibody secreting cells in the blood stream could provide a marker of active CMV infection and thus constitute of tool for the diagnosis and the early treatment of CMV opportunistic infection in AIDS disease and in other cases of immune deficiency.

M.B.P.128 A RANDOMIZED CONTROLLED CLINICAL TRIAL OF FOSCARNET FOR THE TREATMENT OF CYTOMEGALOVIRUS RETINITIS IN PATIENTS WITH ACQUIRED IMMUNODEFICIENCY SYNDROME

Polis, Michael*; Davey, R.*; Lane, H.*; Manischewitz, J.**; Masur, H.*; Palestine, A.*; et al.
*National Institutes of Health; **Food and Drug Administration, Bethesda, MD, USA.

Objective. To evaluate foscarnet (trisodium phosphonoformate) for the treatment of cytomegalovirus (CMV) retinitis in persons with AIDS.
Methods. Foscarnet has been shown anecdotally to be effective for the treatment of CMV retinitis, a sight-threatening infection for which there is no approved therapy in the US. To evaluate it critically, a randomized controlled clinical trial was designed to compare foscarnet, with and without AZT, to AZT alone in the treatment of non-sight threatening CMV retinitis. Patients on the AZT arm are eligible for open label foscarnet once progression is documented. Foscarnet is given at a dose of 60 mg/kg intravenously q8h for a 3 week induction period followed by 90 mg/kg daily maintenance, both adjusted for renal function, until progression of retinitis is noted. Evaluation of retinitis and progression is performed by a masked reading center from retinal photographs. A total enrollment of 48 subjects is planned.
Results. Eleven patients have been seen for ophthalmologic and medical screening in the first 2 months. One did not have CMV retinitis and 1 had a sight-threatening lesion. Three who had eligible eye lesions were initially medically ineligible; 1 required treatment for *Pneumocystis carinii* pneumonia (PCP), 1 was intolerant to AZT, and 1 had HIV encephalopathy. Of the 6 patients enrolled thus far, 2 were randomized to each of the 3 arms. Initial leukocyte counts ranged from 1.6K to 3.0K/mm^3 (median 1.9K), total granulocytes ranged from 1058 to 2520/mm^3 (median 1168), and T4+ counts ranged from 6 to 31/mm^3, (median 10). Five subjects had PCP and 1 had CMV retinitis as their first AIDS-defining infections.
Conclusions. Many persons screened for this study have been ineligible due to inadequate ophthalmologic and medical evaluation prior to presentation. Baseline and interim data and retinal photos showing progression of retinitis and response to foscarnet will be presented.

M.B.P.130 TREATMENT WITH GANICICLOVIR (D.H.P.G.) IN H.I.V. CARRIERS WITH CMV IN THE BRONCHOALVEOLAR LAVAGE :

Michael Finaud*, C. Tamalet** and P. Casanova*.
Hôpital Conception, *Infectious Diseases Unit; **Virology Unit, Marseille, France.

Objective : Describe the effects and long term follow up of treatment with Ganciclovir (DHPG) in HIV carriers when CMV is isolated from bronchoalveolar lavage.
Methods : in a serial of 21 patients with wild symptoms of pneumonitis (caugh, fever, dyspnea, interstitial abnormalities)or without pulmonary symptoms but fever ; We had treated with Ganciclovir 5 mg/kg twice daily for 14 days CMV was systematically cultured from the bronchoalveolar lavage; this serial concern all HIV carriers group II, III and IV of CDC'S all positive for CMV but without any other opportunistic infection.
Results : 16 patients received Ganciclovir ; 5 received no treatment.
2 patients had a disease free survival period characterized by no relapse and no opportunistic infections for 36 months ; 1 for 24 months ; 7 for 18 months, 4 for 12 months and 2 for 6 months. Of the five who did not receive treatment ; one died at 3 months of CMV pneumonitis ; 3 developped others opportunistic infections after 6 months and 1 after 12 months.
No serious side effects were observed.
Conclusion : Ganciclovir when CMV is isolated from bronchoalveolar lavage is safe and could protect the immune system of cytopathic effects of CMV in HIV carriers and could delay the apparition of opportunistic infections.

M.B.P.132 EFFICACY AND TOXICITY OF GANCICLOVIR MAINTENANCE TREATMENT IN AIDS-RELATED CMV RETINITIS.

Rozenbaum Willy, Cherakharian S.; Zeacun L.; Vareghi M.; De Sahb R.; Thomas R.*
Infectious Disease Unit, Rothschild Hospital, Paris, France; *Syntex Research London, G-B.

Objective. To evaluate the efficacy and toxicity of Ganciclovir (G) maintenance treatment for CMV retinitis in AIDS patients, as compared to the absence of such therapy.
Methods. Patients with CMV-retinitis were randomized in two groups: I) with maintenance treatment 5 mg/kg/d 5 days/weeks; II) without maintenance treatment; and were followed-up for 3 months. In both groups the CMV-retinitis was first treated for at least 20 days with 10mg/kg/d of G. 7days/week. Patients had weekly complete ophtalmologic examinations, and hematologic toxicity was evaluated.
Results. 20 patients were enrolled in the study. Results concern 14 patients (13 m., 1 f.) mean age: 40 years (r: 28-63), mean Karnofsky index: 75% (r: 50-100%), randomized in two groups (I:8 pts, II:6pts), comparable for clinical status, Zidovudine treatment, as well as initial treatment (mean duration: 24.7 days, r: 20-35). Patients in group I relapsed after a mean 4.6 weeks, 1.25 times whereas those in group II relapsed after a mean 2.6 weeks, 1.8 times (Figure 1). 3 patients died in group I. There was no difference in parameters studied for toxicity (table 1).

	[illegible]		T-test	[illegible]		T-test
	[illegible]	[illegible]		[illegible]	[illegible]	
[illegible]	[illegible]	1700	NS	1000	[illegible]	NS
[illegible]	1000	[illegible]	NS	[illegible]	[illegible]	NS
[illegible]	10.30	10.10	NS	10.50	[illegible]	NS
[illegible]	[illegible]	176	NS	210	[illegible]	NS

Conclusion. Treatment of AIDS involves use of multiple toxic drugs. Although drug toxicity was comparable in the groups, patients on maintenance relapsed less frequently and later than the group II patients. These results have pratical implications as far as drug association and patients confort are concerned.

M.B.P.133 FOSCARNET CONTINUOUS INFUSION IN HSV INFECTION WITH AIDS.

Schlacht I., Volonterio A., Genova F., Villa M.R., Errante I., Caggese L.
Niguarda Ca' Granda Hospital,Milan,Italy.

Objective. Foscarnet treatment of Acyclovir resistant Herpes simplex (HSV) recurrent genital infection in AIDS.
Methods. A 33 years old man with HIV infection and HSV chronic recurrent infections developed clinical resistence to Acyclovir. Massive localisations in the penis, scrotus and pubic area were subsequently treated with Foscarnet, 50 mg/Kg daily in continuous infusion for several therapeutic cycles. Viral isolation from lesions was obtained. Therapy was administered from July 13, 1988 to August 18, 1988; from September 23 to October 8; from December 27 1988 to as of now. Discontinuation was due to renal impairment.
Results. After 30 days of therapy, the massive lesions were almost completely healed, HSV was not isolated from them. Mild anemia developed. Progressive renal impairment, with elevation of serum creatinine up to a maximum of 2,4 mg/dl suggested drug-dosage reduction and subsequent discontinuation of therapy. Relapse of lesions occurred after 8 weeks, and retreatment with Acyclovir was ineffective. Again, treatment of HSV with Foscarnet yelded response, and therapy is now ongoing with dosage-reduction due to creatinine elevation. No clinically relevant calcium elevation was noticed, even if serum calcium decrease was noticed.
Conclusions. Foscarnet is an active drug on HSV infections in AIDS patients. Continuous administration was a safe modality due to predictability of progression of serum creatinine elevation. Its use in Acyclovir-resistant HSV infections is warranted.

M.B.P.135 INTESTINAL HIV EXPRESSION IN AIDS PATIENTS WITH CYTOMEGALOVIRUS COLITIS

Kotler, Donald P*; Reka, S*; Cronin, W**; Borcich, A*; Tierney, AR**
*St. Luke's-Roosevelt Hospital Center, Columbia University;
**Lenox Hill Hospital, New York, NY, USA.

Objective To determine if intestinal HIV expression is augmented by the development of cytomegalovirus colitis (CMV).
Methods Rectal biopsies from 57 AIDS patients with (25) or without (33) CMV colitis were assayed for HIV p24 content by antigen capture ELISA (Coulter). Immunoperoxidase stains of tissue sections, using monoclonal anti-p24 (Dupont), were performed on selected specimens to localize cellular HIV.
Results HIV p24 was detected in 60% of rectal biopsies from patients with CMV colitis and 64% of patients without CMV colitis. Tissue p24 content was lower in patients with CMV colitis than in those without this complication (63±21 v 135±38 pg/mg prot, NS). Immunoperoxidase stains demonstrated p24 antigen in lamina propria mononuclear cells, intraepithelial lymphocytes and crypt epithelial cells. In contrast, the vast majority of CMV inclusions were found in vascular endothelial cells. Localization of p24 in CMV inclusions was seen only in a few cases.
Conclusions The occurence of CMV colitis does not appear to stimulate HIV production in the intestine, though such interaction may be demonstrated in vitro. The lack of stimulation of HIV by CMV may be related to reactivation in different cellular reservoirs.

M.B.P.137 DEMOGRAPHIC AND EPIDEMIOLOGICAL CHARACTERISTICS OF HIV POSITIVE BLOOD DONORS IN CATALONIA

[illegible], Barbo E and Segura A., Department of Health, Generalitat de Catalunya, Barcelona, Spain .

Objectives: 1.- To estimate the evolution of HIV infection prevalence among blood donations. 2.- To estimate the prevalence of hepatitis and luetic infection among HIV positive blood donors. 3.- To describe the demographic and behavioral characteristics of HIV positive donors.
Methods: The total number of performed blood donations is collected in a monthly basis from all the 25 existing blood banks in Catalonia (6 million inhabitants). HIV testing (including confirmatory test) is mandatory since october 1986. Sociodemographic and behavioral information is collected sistematically with a standarized form for all detected HIV + donors and entered in a centralized database. Data on HBsAg and lues serology has been retrospectively assessed.
Results: From 1985 to 1988, 153 donations were found HIV +. The period prevalence of HIV + donations computed per thousand, in 1986 was 0.27, in 1987 0.36 and during the first nine months of 1988 it was 0.33. Among the identified HIV + donors, 2 (1.96%) were HBsAg positive and 10 (6.53%) were RPR and confirmatory test positive. Table 1 shows their transmission group distribution by sex.
TABLE 1 :

TRANSMISSION GROUP	MALE	FEMALE	TOTAL	AVERAGE AGE
IVDA	45	10	55 (40.7%)	36
Homosexual men	23	-	23 (17.0%)	32
Bisexual	10	-	10 (7.4%)	40
Heterosexual	13	17	30 (22.2%)	32
Unknown	22	3	25 (18.5%)	34
Not yet reported	13	5	18 -	29

Conclusions: Although the prevalence increases it does not reflect the important increment of AIDS cases reported during the same period. While among AIDS cases of our community and selected series of HIV infected patients, IVDA account for more than 60% of them, and heterosexual transmission range between 2 and 10%, among HIV + blood donors the proportion of IVDA is lower and heterosexually acquired HIV infection is much higher. Blood donors have probably special features that jeopardize any comparison with other groups, nevertheless we suggest that patients infected through an heterosexual contact are less sensitive to selfexclusion.

M.B.P.134 PREDOMINANCE OF POLYMORPHONUCLEAR LEUKOCYTES IN CEREBRO-SPINAL FLUID OF AIDS PATIENTS WITH CYTOMEGALOVIRUS RELATED POLYRADICULO(MYELO)PATHY.

De Gans, Jan*; Tiessens, G.**; Portegies, P.* and Troost, D.*. *Academisch Medisch Centrum, 1105 AZ Amsterdam, **Vereeniging voor Ziekenverpleging Prinsengracht, Amsterdam, The Netherlands.

Objective. A spectrum of cytomegalovirus (CMV) related neurological complications has been identified in patients with AIDS including encephalitis, myelitis and polyradiculopathy. Proving CMV is the etiological agent in these cases is very difficult. Cerebrospinal fluid (CSF) cultures are often negative in CMV infection and immunohistochemistry and in situ hybridization of specific specimens are not done routinely. Availability of antiviral therapy makes early diagnosis of CMV related neurological complications important. At least seven cases of CMV polyradiculopathy have been described. Five of these patients had a predominance of polymorphonuclear leukocytes in CSF. Aim of the study was to assess the significance of this phenomenon in CMV related neurological disease.
Methods. Clinical records and diagnostic studies of 241 neurologically assessed HIV-1 seropositive patients (28 CDC II/III, 13 ARC and 200 AIDS) were reviewed and results of CSF examination were evaluated.
Results. CMV encephalitis was diagnosed in one patient at autopsy. Four patients showed subacute progressive flaccid paraparesis and CMV polyradiculo(myelo)pathy was diagnosed by immunohistochemistry and in situ hybridization of specific specimens. In 143 patients CSF examination was performed. CSF pleocytosis was found in 58 patients showing predominance of polymorphonuclear leukocytes in seven: CMV polyradiculo(myelo)pathy (4), Listeria meningitis (1), Cryptococcal meningitis (1) and Pneumococcal meningitis (1). In CMV encephalitis no pleocytosis was seen. CMV was cultured from CSF in two cases of CMV polyradiculo(myelo)pathy.
Conclusion. Predominance of polymorphonuclear leukocytes in CSF of AIDS patients with subacute progressive flaccid paraparesis is indicative for CMV polyradiculo(myelo)pathy.

M.B.P.136 ELECTRON MICROSCOPY OF AIDS RELATED CYTOMEGALOVIRUS (CMV) INFECTION OF THE LUNG.

Bauer,Pierre G.*;Basílio,C.A.**;Fialho,F.**;Valle,H.A.**;Sion F.S.**;Sá,C.A.**. *Virology,FIOCRUZ,Box926,Rio,Brasil; **Hospital Gaffrée e Guinle,UNI-RIO,Rio,Brasil.

Objective. To analyse ultrastructural features of CMV infections of AIDS lung autopsies.
Methods. Specimens of AIDS lung autopsy with CMV infection and Kaposi sarcoma were prepared for light and electron microscopy. Paraffin blocks of histological material were reprocessed for ultrastructural investigations.
Results. The main CMV infected cell in the present study was the pneumocyte, with indications of infection of both types. It contained a characteristic, ramificated nuclear inclusion and numerous cytoplasmic vacuoles full of viruses, visible as granules in semithin sections. All evolution steps from viral capsids in the nucleus to the mature virions in cytoplasmic vacuoles could be observed. Strange vesicle and tubule formation in the nucleus and cytoplasm suggested some aberrant virus production. Some cells revealed dense round bodies characteristic of CMV infections. Hyaline membranes were present in CMV infected regions of the lung. Ultrastructural features, known from tumor cells, like strong convoluted heterochromatic nuclei, nuclear pockets, perinuclear filament bundles and nuclear inclusions remaining monoclonal gammopathies were observed in different cell types. The application of electron microscopy to histological material revealed many of the mentioned CMV characteristics in spite of the poor fixation.
Conclusions. Ultrastructural studies furnished usefull new data about CMV infection, evolution and related pathologies, also in retrospective analysis.

M.B.P.138 A SAFER TEST TUBE FOR HIV AND OTHER VIRAL MARKER TESTS

Sioufi Habib A.*, Jacobson M.S.**, Renaud M.A.** and Kevy S.V.**, *Medcon R & D, Brookline, Massachusetts, U.S.A. **The Children's Hospital, Harvard Medical School, Boston, Massachusetts, U.S.A.

Objective. To test a modified evacuated test tube with an HIV neutralizing agent (HMA-2) to reduce and/or possibly eliminate the risk of contracting HIV by healthcare providers.
Method. Serum from 9 HIV positive (+) and 2 HIV negative (-) blood samples, by EIA and Immunoblot assay, were divided into two equal aliquots. To the 1st aliquot HMA-2 was added to give a final concentration of 0.1%, an equal volume of 0.9% NaCl was added to the 2nd aliquot (control). Samples were blindly assayed for the following viral markers: HIV by either EIA or Immunoblot assay, HBsAg, HBsAb, Anti-HBc, ALT and CMV. Other samples with/without HMA-2 were assayed for the routine chemistry tests i.e. Blood Sugar, BUN, Creatinine, Calcium and Electrolytes.
Results. 0.1% HMA-2 did not interfere with the above mentioned viral marker tests, all (+) samples were (+) and all (-) samples were (-) with/without HMA-2. All the chemistry tests with/without HMA-2 were within ±5%. The preliminary study has shown that 0.1% HMA-2 reduced, by at least 2 logs, a viral particle concentration of 500,000 TICD50 in 1 ml of whole blood.
Conclusion. A modified evacuated test tube with HMA-2 can provide an additional safety tool to reduce the risk of contracting HIV by healthcare workers handling patient specimens without compromising HIV and other viral marker tests. The technology will be expanded to include other test tubes.

M.B.P.139 HIV SCREENING OF COMMERCIALLY AVAILABLE BLOOD PRODUCTS IN INDIA.

Tripathy S.*, Chaudhuri R.*, Singh Y.N.*, Seth**P, Varghese T.*, and Malaviya A.N.*
* Clinical Immunology Services, Department of Medicine, AIIMS;
** Department of Microbiology, AIIMS, New Delhi, INDIA

Objective To describe the result of HIV screening of commercially available blood products in India.

Methods 105 samples of blood products (viz-immunoglobulin preparations, Factor VIII cryoprecipitate and a variety of blood products) of 1 American and 5 Indian companies were tested for the presence of HIV antibodies using the Wellcozyme competetive ELISA kit. Presence of HIV antibodies was confirmed by Western Blot (Dupont).

Result Of these 105 samples, 31 were found to contain HIV antibodies by the ELISA method. They were subsequently confirmed by the Western Blot test. Their results and their medical, social and legal implications have generated a lot of controversy in the country.

M.B.P.140 DETECTION OF HIV MARKERS PRIOR TO IgG ANTIBODY SEROPOSITIVITY IN PLASMA DONORS.

Susan L. Stramer*; Heller, J.S.*; Coombs, R.W.**; Parry, R.V.***; Ho, D.D.****; Stewart, J.L.*; Allain, J.P.*.
*Abbott Labs, N. Chicago IL; ** Univ of Washington, Seattle WA; ***Central Public Health Laboratory, London UK; ****UCLA School of Medicine, Los Angeles CA, USA.

Objective. Determine the sequence of occurrence of HIV markers presero conversion. Assess the utility of HIV antigen (HIV Ag) detection in plasma donors.
Methods. Preseroconversion serial samples at 3 to 7 day interval were obtained from 7 healthy plasma donors who seroconverted (US licensed HIV antibody screen positive; licensed western blot positive). HIV plasma culture, HIV antigen, IgM anti-HIV, anti gp41 antibody, and radio immunoprecipitation were performed on 36 samples available.
Results. In 5 donors, HIV antigen was detected prior to or simultaneously with IgG anti HIV. All HIV Ag positive samples were infectious for cultured normal peripheral blood mononuclear cells; most were also IgM anti HIV positive. The disappearance of HIV Ag and, to a lesser extent, of plasma infectivity was concurrent with the development of the IgG immune response. Although the improved sensitivity of recombinant antigen derived screening or anti gp41 assays shortened the window period preceeding seroconversion, HIV antigenemia and plasma viremia were the only markers of HIV infection for several days in 2 cases.
Conclusion. HIV infectious units from plasma donors can be eliminated from the plasma supply by HIV Ag screening.

M.B.P.141 RISK FACTORS FOR HIV AMONG NEW YORK BLOOD DONORS IN 1988.

Gaynor, Suzanne; Kessler, D.; Berge, P.; Andrews, S.; DelValle, C.; New York Blood Center, New York, NY, USA.

Objective: To evaluate current trends in risk factors for HIV Ab+ blood donors in order to update educational efforts to protect the blood supply.
Methods: We compared blood donor risk factor patterns identified from Feb.-Dec. 1988 with April 1985-May 1986 data as reported by Rabkin, et al.

Results:	Feb-Dec 1988	April 1985-May 1986
Units Collected	415,000 (Jan-Dec)	470,000
Anti-HIV positive	178(.04%)	470(.1%)
Donors interviewed	113(64%)	214(46%)
Risk Factors		
Homo-Bisexual	31%	65%
IVDU	11%	4%
Blood Recipient	1.7%	1.4%
Het. High Risk Partner	29%	15%
Het. Multiple Partner	5%)	
Heterosexual Unk. Risk	17%)	7%
Other Risk	8%)	

Donor interviews indicate that, of heterosexuals with high risk partners, 68% have a greater perception of risk and ability to transmit HIV by transfusion than do heterosexuals with 1 or more partners of unknown risk (38%).
Conclusion: There has been a clear shift in risk factors among blood donors from homosexual/bisexual activities toward the IVDU and heterosexual donor population. As education has been effective in decreasing the donating homo-bisexual population, renewed educational efforts should target sexually active heterosexuals.

M.B.P.142 SELF-EXCLUSION BY HIV ANTIBODY POSITIVE BLOOD DONORS

Gaynor, Suzanne; Kessler, D.; Andrews, S.; DelValle, C.; New York Blood Center, New York, NY, USA.

Objective: To assess the self-exclusion (SE) behavior of HIV antibody seropositive blood donors as related to knowledge of well-defined risk factors.

Methods: 113 HIV Ab+ blood donors were interviewed and counseled in 1988. SE status and risk for HIV infection noted during the counseling sessions were retrospectively quantified.

Results: Eighteen (15.9%) self-excluded, while, overall only 1% of blood program donors self-exclude. Criteria for donor deferral(*) were met by 81 (71.7%); 28 others were either heterosexual or transfusion recipients. Three donors had multiple risks; no information was available for the rest. Donor interviews indicate those who do self-exclude have a higher level of AIDS education, perceive themselves at higher risk, and are aware of the risk of HIV transmission by transfusion. (87.5% vs. 10.3% non self-exclusion)

	Total	%Total	Self-Exclusion	
Results:			# Yes	% Yes
*Homosexually active males	35	31.0%	11	31.4%
*Heterosexual/High Risk Partner	33	29.2%	3	9.1%
*Intravenous Drug User	12	10.6%	1	8.3%
*Haitian	1	0.9%	0	
Heterosexual/Unknown Other Risk	20	17.7%	2	10.0%
Heterosexual/Multiple Partners	6	5.3%	0	
Transfusion Recipient	2	1.8%	0	
Others	8	7.1%	1	12.5%

Conclusion: As individuals not in identified risk groups for self-exclusion become infected, additional efforts are essential to better educate donors of risks of HIV transmission and to increase the use of self exclusion.

M.B.P.143 CHANGING PROFILE OF HIV-SEROPOSITIVE BLOOD DONORS.

Ballem, Penny; Buskard, N; Elliot, M; Lord, S; Sinclair, M.
Canadian Red Cross Blood Transfusion Service, Vancouver, B.C.

Testing for the HIV virus was instituted in October 1985 in B.C. In the 3 years since, 453,000 units have been tested and 25 donors identified as HIV positive (.005%). 8 donors were also identified in the investigation of 14 cases of transfusion associated AIDS (TAA). 32 of the 33 seropositive donors were in self-identified high risk groups: 31 homosexual or bisexual males and 1 former partner of a bisexual male. All 8 donors implicated in TAA had self deferred an average of 26 mo. (range 6-34 mo.) prior to commencement of screening for anti-HIV in B.C. All 8 had been regular blood donors donating q3-6 mo. up to the time of their self deferral. In contrast, of 25 donors identified during the first 3 years of screening: 3 (bisexual males) were regular donors (q3 mo.) and were picked up in the first few months of testing; none felt at risk for HIV infection. 5 were q3-6 mo. donors up to an average of 22 mo. prior to screening (range 16-40 mo.) and then self-deferred. However, 4 returned as donors within 5 mo. and 1 at 36 mo. post testing. Another 4 donors are sero-converters; of these, 3 had never donated blood prior to testing, 1 donated on 1 prior occasion. Of the remaining 13 donors, 3 had donated once prior to testing (2 within 1 mo. of testing); 10 were new donors. Although donors implicated in TAA had voluntarily self-deferred well before testing for HIV and did not return, there remain self-admitted high risk people who have enrolled as new donors since the advent of screening, presumably to be tested. Furthermore, some previously self-deferred donors in high risk groups are now returning to donate. This underlines the need for continued efforts to discourage such behavior and for creative screening methods which will identify such donors on the clinic.

M.B.P.144 IMMUNOPHENOTYPES OF ANTI-HTLV-I POSITIVE (+) BLOOD DONORS

Transfusion Safety Study Group* represented by Fletcher, Mary A.** *Participating institutions in New York City, Miami, Detroit, Seattle, San Francisco, and Los Angeles, USA, **University of Miami, Miami, Florida, USA.

Objective To define the lymphocyte subsets of anti-HTLV-I (+) blood donors.
Methods The South Florida component of the TSS/NHLBI Donor Repository contains sera from 29,931 blood donations in late 1984 and early 1985. EIA screening with RIA, immunoblot, and RIPA confirmation, showed confirmed 23 donors as anti-HTLV-I (+). The 11 donors enrolled in 1988 were still EIA and RIA (+); 6 were HTLV-I culture (+), 5 were (-); 7 were male, ages 39-70; 4 were female, ages 51-63. None were IV drug abusers. Each subject was compared with sex- and age-matched controls. Lymphocyte immunophenotyping has been carried out by 2-color flow cytometry using 11 pairs of antibodies.
Results One anti-HTLV-I (+) donor, who was also anti-HIV-1 (+), had immunophenotypic changes expected for the latter. The 10 anti-HTLV-I (+), anti-HIV-1 (-) donors did not differ from controls in CD2 and subsets CD2+Tal+ or CD2+MO1+, CD4 and subset CD4+CDw29+, CD8 and subset CD8+Tal+, CD20 and subset CD20+CD21+. However, 9 of the 10 had values for CD4+CD45r+ and CD14+ cells above the median for controls ($p <.05$), and all 10 had NKH.1+ cell counts above the median ($p <.01$).
Conclusion HTLV-I infection for at least 4 years did not affect lymphocyte subsets to suggest immunosuppression in these donors. The statistically significant elevations in the CD45r subset of CD4 cells (the subset thought to induce activation of suppressor/cycotoxic T cells) and in monocytes (CD14) and natural killer cells (NKH.1) may result from infection with a lymphoproliferative virus, or represent a usual response to a chronic viral infection in subjects who had no obvious HTLV-I related diseases. (Sponsored by Contract No. NO1-HB-4-7003 of the National Heart, Lung, and Blood Institute.)

M.B.P.145 CLOTTING FACTOR TREATMENT AND CD4 COUNTS IN ANTI-HIV+ HEMOPHILIACS.

The Transfusion Safety Study Groups represented by Gjerset, George F.** *Participating institutions in New York City, Miami, Detroit, Seattle, San Francisco, and Los Angeles, USA, **Puget Sound Blood Center, Seattle, Washington, USA.

Objective. To determine whether reductions in CD4 counts among anti-HIV-1(+) hemophiliacs are related to type or intensity of treatment.
Methods. Data for anti-HIV-1(+) patients with factor VIII (FVIII) or IX deficiency were analyzed by type and amount of treatment received from 1981-1985, defined as FVIII units, FIX units or FVIII units from cryoprecipitate (cryo). Analysis was limited to 344 patients treated with FVIII concentrate, FIX concentrate or cryo only. Statistical inference was based on the rank correlation coefficient between amount of treatment and CD4 count.
Results. Median CD4 counts shown by quartile of treatment. Units = annual mean/patient.

Quartile	FVIII (n=262) units	CD4	correlation r	p	FIX (n=56) units	CD4	correlation r	p	cryo (n=14) units	CD4	correlation r	p
1	to 20,663	522			to 17,880	322			to 2,200	784		
2	to 53,606	491	-.22	.001	to 46,700	449	-.06	.67	to 14,200	478	-.63	.017
3	to 110,706	282			to 83,000	444			to 157,600	644		
4	to 686,983	338			to 356,287	352			to 290,600	330		

Conclusion. Increasing treatment was correlated with lower CD4 counts in those receiving FVIII or cryo, but not FIX. Heterologous proteins could be responsible for the observations in FVIII-treated patients. Relatively little of the variability in CD4 (r^2), however, is related to treatment intensity, which may itself simply be an index of increasing duration of HIV infection. (Sponsored by Contract No. NO1-HB-4-7003 of the National Heart, Lung and Blood Institute.)

M.B.P.146 SEROLOGICAL EVIDENCE OF PRIOR SEXUALLY TRANSMITTED DISEASES IN HIV-1 SEROPOSITIVE BLOOD DONORS

Alan E. Williams, K.W. Creedon, T. Grandinetti, M.T. Sullivan, and the American Red Cross Collaborative HIV Study Group, Jerome H. Holland Laboratory, Rockville, MD. USA.

OBJECTIVE To serologically characterize HIV-1 seropositive blood donors who deny prior AIDS risk behavior.
METHODS AIDS risk behaviors were defined as: a)IV drug use or sexual contact with an IV drug user, or b)direct or primary partner contact with a gay or bi-sexual male. These data were collected by in-person interview following test result notification from 156 HIV seropositive former blood donors and 155 age, sex and race-matched controls. All subjects were tested for anti-HBc, anti-CMV, anti-chlamydia, and anti-HSV.
RESULTS Prior behaviors likely to have resulted in increased AIDS risk were identified by in-person interview for 131/156 HIV+ former donors (RISK). Twenty five donors were classified as having no identifiable risk (NIR). The proportion of both RISK and NIR HIV+ donors having additional STD markers was significantly higher than controls for all markers. In contrast, the proportions of NIR and the RISK HIV+ individuals reactive for all STD markers except anti-HBc did not differ significantly.
CONCLUSIONS HIV+ donors as a group are significantly more likely to have serological evidence of prior exposure to other STDs. This exposure is also evident for donors who deny traditional AIDS risk activities. While none of the STD-related assays studied would have sufficient predictive accuracy to be used for blood screening purposes, they may serve as a mechanism for further characterization of these individuals.

M.B.P.147 PHOTOINACTIVATION OF HIV-1 WITH MEROCYANINE 540

Sunstrum, James C., Harvey, R.L., Sensenbrenner, L.L.
Wayne State University, Detroit, Michigan, 48201, and Veterans Administration Medical Center, Allen Park, Michigan, U.S.A.

Objective. Merocyanine 540 (MC 540),a lipophilic dye,inactivates enveloped viruses following exposure to white light.We conducted an experiment to determine if MC 540 with light inactivates HIV-1,since phototherapy may be useful for inactivating viruses transmitted by blood transfusion.
Methods. Cell-free supernatant from H9/HTLV-III$_B$ cells was mixed with MC 540 (30 ug/ml),then exposed to white light for 60 minutes.Uninfected V8 cells were added to treated viral supernatant and virus adsorbed eighteen hours at 37°C in 5% CO_2 incubator.V8 cells were washed in PBS X 2,resuspended,and incubated at 37°C in 5% CO_2 for 10 days.Supernatant p24 antigen (Abbott) was measured at 7 and 10 days post-infection.
Results.

Specimen	p24 optical density Day 7	Day 10
HIV (no light, no MC 540)	0.237 (+)	0.818 (+)
HIV (no light, with MC 540)	0.450 (+)	1.673 (+)
HIV (with light, no MC 540)	0.139 (+)	0.301 (+)
HIV (with light, with MC 540)	0.044 (-)	0.056 (-)

Conclusion. MC 540 with white light inhibited HIV replication as determined by p24 antigen immunoassay.Studies are in progress to determine if MC 540 has similar activity against cell-associated virus.

M.B.P.148 p24 HIV ANTIGEN SCREENING OF BLOOD DONORS

Eberle, Josef*; Gathof, B[1*]; Bäcker, U[1*]; Gossrau, E[3*]; Stute, R**; Baumgarten, K[2*]; Bergmann, H[3*]; Reissigl, H[2*]; Gürtler, L*; Deinhardt, F*;
*Pettenkofer Institute, University Munich, FRG, *Blood Transfusion Service, Red Cross, [1*]Munich, FRG, [2*]Austria, [3*]Berlin, FRG, **Blood Transfusion Service of Saarland, Federal Republic of Germany.

Objective. Screening blood donations only for HIV-1 antibody (anti-HIV) leaves open the possibility that a donor was in the period (4 -12 weeks after infection) of beeing anti-HIV negative but infected and possibly positive for HIV-antigen (HIV-Ag). So several blood centers have evaluated the advantage of HIV-Ag screening in populations with different HIV prevalences.
Method. HIV antigen capture immunoassays (Abbott, N. Chicago, Il.) were used.
Results.

	number of donations	Anti-HIV+ /HIV-Ag+	Anti-HIV+ /HIV-Ag-	Anti-HIV- /HIV-Ag+
Bavaria	229,879	0	7	0
Berlin	65,481	0	15	0
Saar	24,117	0	1	0
Vienna	215,783	1	9	0
Linz	52,577	0	2	0
Innsbruck	32,180	0	3	0

It is particularly important that 6 donors became Anti-HIV positive 2 to 8 weeks after having been tested HIV-Ag negative.
Conclusion. In these 620,017 blood donors HIV-Ag testing failed to detect

M.B.P.149 HIV SEROPREVALANCES AMONGST HEALTH BLOOD DONORS IN 31 HOSPITALS IN ZAMBIA

Luo N.P*, Dallas ABC*, Chipuka L.*, Nshimbi R.*, Tedder R.*, Siyambango J.*, *Middlessex Hospital, London UK and *University Teaching Hospital, Lusaka, Zambia.

OBJECTIVE. To screen blood for HIV infections in all the Blood Transfusal in Zambia with a view to limiting Transmission. Secondly to provide information on the seroprevalance of HIV among health blood donors in Zambia.
METHOD. Using a National Blood Transfusion record book all donors were interviewed in 31 hospitals in Zambia, Sex, Marital Status, Address, Age, Social behaviour and Travel was recorded. HIV abs was screened using Welcozyme ELISA.
RESULTS. HIV seroprevalances varied from place to place. The rural areas had 0%. The urban rural had 0-3% while the urban areas had 6-10%. The big cities recorded up to 11%.
CONCLUSION. HIV is a new disease in Zambia and is currently confined mostly to big cities and any part of zambia with urban influence.

M.B.P.150 RISK OF HIV-1 TRANSMISSION BY BLOOD TRANSFUSIONS IN SAN FRANCISCO PRIOR TO ANTI-HIV-1 SCREENING

Busch, Michael[*], Samson, S.[*], Young, M.[*], Ward, J.[**] and Perkins, H.[*]
[*]Irwin Memorial Blood Centers, San Francisco, California, and [**]Centers for Disease Control, Atlanta, Georgia, USA.

Objective. To estimate the proportion of blood transfusions that were infectious for HIV-1 during each of the seven years preceding introduction of routine anti-HIV-1 screening.
Methods. 1,554 previous donations by 309 former blood donors now known to have AIDS or HIV-1 antibody were plotted according to donation date. Using the observed seropositivity of late 1984 donors (0.24%), and assuming a parallel seroprevalence with that reported for other high-risk persons in San Francisco between 1978 and 1985, the proportion of all donors who were high-risk and HIV(+) was extrapolated for each earlier time point. The likelihood of recipient infection per unit exposure was then calculated by multiplying by the known infectivity rate (0.90) of a seropositive transfusion.
Results. The risk of infected transfusions rose exponentially from 1978 (<.01%) through 1982 (1.2%). The risk plateaued in 1983 and then declined precipitously in mid-1984, despite continued spread of the virus in the local community.
Conclusion. The derived risk/time estimate is validated by an alternate risk estimate based on reported dates of transfusion of known infected recipients, and has been of value in designing recipient counselling, notification and testing strategies.

M.B.P.151 TRANSMISSION DU VIH1 PAR TRANSFUSION: DECROISSANCE DU RISQUE.

Jullien, Anne Marie; Couroucé, AM; Richard, D; Girard, M; Elghouzzi, MH; Habibi, B. Fondation Nationale de Transf. Sang., Paris, France.

Objectifs : Evaluer l'infectivité des dons de sang séronégatif de donneurs ultérieurement séroconvertis et le risque annuel de transmission du VIH1.
Méthodes : Une procédure d'enquête a été appliquée lors de la découverte d'une séropositivité VIH1 chez un donneur régulier. Les receveurs des produits issus du don précédant cette découverte d'un an maximum ont été identifiés et testés. Le risque a été calculé selon la même approche que S.KLEINMAN et al. (Transfusion 1988, 28 : 499-501).
Résultats : Du 1/07/85 au 31/12/88, 805.118 dons ont été testés : 430 donneurs ont été confirmés VIH1 positif. Parmi eux 58 avaient fait au moins un don séronégatif avant le dépistage de la séropositivité dont 48 dans un délai de moins d'un an. Parmi les 50 receveurs de ces 48 dons, 23 étaient décédés (46 %) et 12 (24 %) ont été testés. Le taux d'infectivité était de 25 % (3/12). Le suivi annuel de l'estimation du risque montre :

Année	Total dons	VIH+ °/..	VIH- suspects	Risque 1:
1985	110.683	0,92	10	36.000
1986	236.897	0,74	19	40.000
1987	237.348	0,43	12	65.000
1988	220.190	0,23	7	110.000

Conclusion : La diminution du risque de transmission VIH1 par transfusion est parallèle à la diminution de la prévalence des donneurs séropositifs. Cette surveillance annuelle mesure globalement l'efficacité du dépistage et de l'exclusion des sujets à risque. Elle permet la comparaison avec les résultats d'autres régions à risque.

M.B.P.152 EXPERIENCE WITH NOTIFICATION AND FOLLOW-UP OF WESTERN BLOT INDETERMINATE DONORS

Gaynor, Suzanne; Hosein, B.; DelValle, C.; Bianco, C.; et al. New York Blood Center, New York, NY, USA.

Objective: Notification, risk assessment and retesting of indeterminate blood donors.
Methods: Donors with ENI ELISA R.R. indeterminate W.B. results on 1985/86 donations were recalled for retesting and interviewing. Donors were originally sent a non-specific letter (A) similar to the one used for anti-HIV positive notification. These donors as a group were more distressed by this correspondence due, in part, to the time interval since the donation.
Results: Based on this adverse response, a more detailed and specific, informational letter (B) was developed, stressing the probability that this finding is not cause for concern. Interviews with 17 donors yielded no risk factor for exposure to HIV.

	Totals	Response Rate	Fear/Anxiety	Curiosity	Other
Letter A	(30)	13 (43%)	4 (30%)	8 (61%)	1 (8%)
Letter B	(20)	4 (20%)	0 (0%)	4 (100%)	0 (0%)

14/17 donors were retested. Seven (50%) of the donors retested were negative on DuPont and Genetic Systems EIA, as well as Biotech W.B. Seven donors retained the same W.B. indeterminate results on retesting.
Conclusion: Based on this preliminary sample, there is no evidence of seroconversion three years after the indeterminate W.B. result. Donors can be notified of their status using an appropriately worded written communication, without undue anxiety.

M.B.P.153 DONORS SHOWING ONLY CORE POSITIVE HIV ANTIBODY: A 3 YEAR FOLLOW UP.

Das, P.C.; de Vries, A.H., McShine, R.L.; Smit Sibinga, C.Th. Red Cross Blood Bank Groningen-Drenthe, Groningen, The Netherlands.

Since antibodies to the core of HIV could herald the early signs of AIDS we have studied 8/17 (7F + 1M) initially reactive donors detected by the first generation test in 1985; they were selected for 6 monthly follow ups. At that time Western blot pattern showed P55 in 5, P55 & P24 in 2 and P55 with another non specific band in 1 subject; all were healthy and there were no 'risk factors' involved. 18 Months later 5/8 were available, remained healthy and capture ELISA tests were negative but in Western blotting 2 donors persisted with positivity, one with P55. In 1988, 6/8 donors were available for follow up. They were apparently in good health and serologically they were entirely negative. Their deep frozen 1985 sera, when retested for HIV antibody by synthetic peptide (Abbott, DuPont), competitive ELISA (Wellcome) or gelatin particle agglutination tests, were entirely negative. It seems therefore that these serological reactions found in 1985 for HIV are a false positive phenomenon most probably due to the presence of contaminants in the reagent and/or cross reactivity by antibodies to other virus.

M.B.P.154 ANTIGENEMIE HIV : DEPISTAGE SYSTEMATIQUE DES DONNEURS DE SANG DE LA REGION PARISIENNE .

VIGNON Dominique TRANSFUSION, Hôpital FOCH, SURESNES, FRANCE

OBJECTIF : La recherche des antigènes HIV1 permettrait,selon des articles récents, de déceler les sujets récemment contaminés, avant séroconversion.
MATERIEL : Le dépistage systématique de l'antigénémie HIV1 fut institué, à chaque don de sang, en octobre 1987. La recherche des anticorps anti-HIV étant par ailleurs réalisée par 2 techniques depuis 1985. 6372 prélèvements furent ainsi examinés, correspondant à 4000 donneurs, dont 756 nouveaux venus dans notre Centre.
METHODES : Pour la recherche des Ag HIV, la méthode fut une technique enzymo-immunométrique de type Sandwich (Organon Lab.); chaque échantillon positif fut repris dans une 2° série de réactifs, puis testé en Western Blot (Epiblot: Organon Lab.) et enfin soumis à neutralisation (Confirmatory/Innotest Organon Lab.° .
RESULTATS : • durant la période considérée, 3 donneurs furent dépistés anti-HIV positifs (2nouveaux, 1 connu) soit une fréquence de 0,08% des donneurs.
• 2 antigénémies furent dépistées de façon reproductible chez un donneur connu et la réaction ne fut pas neutralisable; 6mois plus tard la fausse positivité persistait, avec un WB négatif; et chez un donneur nouveau avec réaction neutralisable et WB négatif; ce donneur fut aussitôt perdu de vue. La fréquence de l'antigénémie fut donc de 1/3997 donneurs séronégatifs en anticorps anti-HIV1, soit 0,023% .
CONCLUSION : Il serait primordial en transfusion, de pouvoir réduire la fenêtre existant entre contamination et apparition des anticorps, alors que plusieurs observations notent que la contamination des receveurs est possible. La faible fréquence d'AgHIV1 dans notre population de donneurs de sang (en majorité fidélisés et connus) était attendue : cette étude ne fournit donc pas d'argument pour cesser le dépistage, au contraire.

M.B.P.155 THE VALUE OF HIV COUNSELLING CONSULTATION MEETINGS AT THE NORTH LONDON BLOOD TRANSFUSION CENTRE (1986 - 1989)

Miller, Riva*; Hewitt, P.**; Moore, C.**; Barbara, J.**; Contreras, M.** and O'Brien, S.**
*Haemophilia Centre, Royal Free Hospital, London, England, **North London Blood Transfusion Centre, Edgware, Middlesex, England.

Objective. To describe how counselling consultation sessions enable the review, modification and evolution of counselling strategies related to HIV in a regional blood transfusion centre (R.T.C.).
Method. A district AIDS Counselling Co-ordinator consults with an R.T.C. team of doctors, nurse and microbiologist on a planned regular basis. The approach is to identify potential problems, rehearse possible solutions and discuss hypothetical and actual sequelae. Topics include strategies for notification and counselling of seropositive donors; donors implicated in transfusion-associated HIV; the impact of assay technology.
Results. Consultation sessions enable R.T.C. staff to define areas of concern, explore solutions, and influence policy structure particularly with regard to other areas of donor counselling e.g. hepatitis B infection. R.T.C. staff also gain insight into otherwise unfamiliar psychosocial concepts.
Conclusion. Transfusion staff have time to plan approaches in advance thus minimising ad hoc decision making. A more open approach to problems has also resulted which enhances information exchange between staff and donors while maintaining complete confidentiality.

M.B.P.156 CHANGES IN THE PREVALENCE OF HIVs AMONG NIGERIAN BLOOD DONORS IN IBADAN, NIGERIA.

Essien, Etim & Saliu, Idris
Dept. of Haematology, University College Hospital, Ibadan, Nigeria.

Objective. To determine the trend in HIV sero-prevalence rate among blood donors in Ibadan.
Methods. Both indirectly remunerative (relative) and non-remunerative (voluntary, panel) blood donor systems have operated in the Blood Bank of this hospital since its inception in 1958. The ratio of one to the other varies depending on several factors. Remunerative donors have been in the majority in recent years. Each prospective donor was questioned on past medical history. Only those not previously jaundiced or on regular drugs were tested by the $CuSO_4$ method. Suitable candidates donated blood and serum samples from pilot bottles were saved and screened by the Wellcozyme and Elavia HIV systems
Results. Between July and December 1986, of 2000 samples tested, 0.01 was positive by Elisa but was not confirmed on Western blot (WB). By contrast between 1.05 & 30.09.88 when 1464 samples were tested, 12 (0.8%) were Elisa positive and 9 (0.1%) were confirmed by WB.
Conclusion. This result indicates that blood transfusion may likely be an important route of HIV transmission in Ibadan. It further emphasizes the need to ensure, as directed by Government, that every unit of blood is HIV-free before it is transfused.

M.B.P.157 ANTI-HIV SCREENING OF BLOOD DONORS IN CANADA (NOVEMBER 1985 TO DECEMBER 1988)

MANKIKAR, SADANAND; ADATIA, A; AND WHITTEMORE, N.B.
THE CANADIAN RED CROSS SOCIETY, OTTAWA, CANADA.

BETWEEN NOVEMBER 1985 AND DECEMBER 1988, THE CANADIAN RED CROSS SOCIETY SCREENED OVER 3,7 MILLION UNITS OF BLOOD FOR ANTI-HIV USING ENZYME IMMUNO ASSAYS (EIA). THE UNITS FOUND TO BE REPEATEDLY REACTIVE BY EIA WERE DISCARDED AND THE ANTIBODY STATUS CONFIRMED BY WESTERN BLOT (WB). DURING THIS PERIOD, 14,313 (0.38%) UNITS WERE FOUND TO BE EIA REPEATEDLY REACTIVE AND WERE DISCARDED. ONLY 395 (0.011%) OF THE UNITS TESTED WERE FOUND TO BE WESTERN BLOT POSITIVE AND THE DONORS WERE INFORMED OF THEIR ANTIBODY STATUS.

ALTHOUGH THE REPEATEDLY REACTIVE RATES WERE NOT SIGNIFICANTLY DIFFERENT WITHIN THE CATEGORIES STUDIED, WB POSITIVE RATES DIFFERED SIGNIFICANTLY. THE ANTI-HIV SEROPREVALENCE WAS TWO TO FOUR TIMES HIGHER IN THE URBAN POPULATION THAN IN THE RURAL POPULATION. THE SEROPREVALENCE IN THE PROVINCE OF QUEBEC REMAINED CONSISTENTLY TWO TO FOUR TIMES HIGHER THAN THE REST OF THE COUNTRY. THE WB POSITIVE RATE WAS SLIGHTLY HIGHER AMONG THE FIRST TIME DONORS THAN IN THE REPEAT DONORS. THE WB POSITIVE RATE WAS FOUR TIMES HIGHER AMONG THE MALE DONORS THAN IN THE FEMALE DONORS. THE HIGHEST SEROPREVALENCE WAS OBSERVED IN THE MALE DONORS OF 17 TO 29 YEARS OF AGE.

DURING THE STUDY PERIOD, THE WB POSITIVE RATE HAS DECREASED CONSIDERABLY, FROM 0.034% IN THE FIRST QUARTER OF 1986 TO 0.005% IN THE LAST QUARTER OF 1988, WHICH MAY BE MAINLY BECAUSE THE DONOR POOL HAS NOT CHANGED DRASTICALLY AND THE WB POSITIVE DONORS ARE PERMANENTLY DEFERRED FROM DONATING.

M.B.P.158 HIV-2 SEROPREVALENCE IN DIFFERENT GROUPS TESTED IN UNIVERSITY COLLEGE HOSPITAL, IBADAN, NIGERIA

Etim Essien & Idris Saliu
Dept. cf Haematology, University College Hospital (UCH) Ibadan, Nigeria.

Objective. To determine the relative frequency of HIV-2 among different groups tested in U.C.H. Ibadan
Methods. U.C.H. is the apex Hospital in South Western Nigeria and is located in Ibadan, the largest city in Africa South of the Sahara desert with an estimated population of about 6 million. A total of 6,385 blood samples have been screened in this centre since July 1987.
Results.

Category	No.screened	Elisa +ve	WB +ve
Blood donors	5720	4	2
Haematology & other patients	337	3	3
Volunteers etc.	324	1	1
Total	6385	8 (0.13%)	6(0.09%)

Two of those who tested positive among patients probably acquired the infection through blood transfusion.
Conclusion. It is concluded that HIV-2 is present among different categories of persons in Ibadan. Transmission in some cases was probably via infected blood transfusion. A study of its effect(s) on the course of other diseases in this environment is being undertaken.

M.B.P.159 TRANSFUSION AND HIV, FINNISH NATIONAL LOOK BACK PROGRAM.

Koistinen, Jukka, Finnish Red Cross Blood Transfusion Service, Helsinki, Finland.

HIV situation in Finland by Dec. 31, 1988: 241 positive, of them 26 with a history of blood donation since Jan. 1, 1982, seven diagnosed at blood donation. The 26 donors gave blood 88 times for 99 products, of which 44 were used and 55 discarded. In addition some parts of 77 units were separated for F VIII, cryoprecipitate, interferon or plasma for albumin.

Results of the blood components used:

	No. of units to hospitals	Patients HIV pos.	HIV neg.	D	NK	No. inform.
Whole blood	9	0	3	4	2	0
Red cell conc. (RBC)	23	3	5	11	1	3
Platelets	10	2*	1	4	0	2
Leukocytes	2	0	1	1	0	0
TOTAL	44	5	10	20	3	5

NK=HIV results of the patient are not known; D=patient has died of reasons not due to HIV; *=one patient received two HIV pos. platelet concentrates.

Two patients died of AIDS after receiving RBC in 1983 (died 1986) and 1984 (died 1987). One received HIV pos. platelets in 1984, started having opportunistic infections in 1988. One received RBC in 1985, got LAS in 1987. The one, who got 2 units of HIV pos. platelets died a year later of leukemia without symptoms of AIDS. Two hemophiliacs are HIV pos. since 1984 due to cryoprecipitate. Of the donors 11 were first time donors, but their donations occurred equally between years 1982-88 suggesting that blood donation was not used for HIV testing.

M.B.P.160 ABSENCE OF HIV SEROPOSITIVITY IN CHILDREN WITH SICKLE CELL ANAEMIA AT KENYATTA NATIONAL HOSPITAL, NAIROBI, KENYA.

Waweru Samuel E. Njora, Meme, J.S., Kinuthia, D.M.W. and Kitonyi, G.W.*
Departments of Paediatrics, and Haematology* University of Nairobi, Nairobi, KENYA

Objective: To find out whether frequent blood transfusions increase the risk of transfusion-related HIV infection in children with Sickle cell anaemia.
Methods: One hundred and ninety-eight children with Sickle cell anaemia were transfused 1-13 times (mean 2,4) between 1982 and 1987. In Kenya routine screening of blood banks for HIV infection began in 1987. The HIV status of these children was compared with 231 non-transfused children: 106 with Sickle cell anaemia and 125 children with haemoglobin AA. In both transfused and non-transfused children age ranges were similar and were 1-12 years. All children were tested with Wellcozyme Elisa test in duplicate. All tests were performed at least 6 months after the last transfusion. Sixty five transfused sicklers were rechecked one year later.

Results: All 429 children were HIV negative.

Conclusions: Out findings suggest that HIV seropositivity is low in Kenyan children. Furthermore, even though blood was unscreened in 1982 - 1987 transfusion did not increase the risk of HIV infection in our study children.

M.B.P.161 RISK OF TRANSMISSION OF HTLV-I BY TRANSFUSION

N. Cohen*, A. Munoz**, James Donahue**, B. Reitz**, O. Frazier*** B. F. Polk**, et al.
*Texas A & M University, College Station, TX; **Johns Hopkins Medical Institutions, Baltimore, MD; ***St. Luke's Episcopal Hospital, Houston, TX. U.S.A.

Objective: A prospective seroepidemiologic study was conducted to determine the incidence (risk) of seroconversion to HTLV-I in a cohort receiving multiple transfusions of blood/blood components screened for antibody to HIV-1.
Methods: Preoperative and postoperative serum samples were collected from 2,749 adult cardiac surgery patients who received 20,963 transfusions of blood components (17,623 cellular components). Preoperative and postoperative samples were serologically compared for evidence of human T-cell leukemia virus type I (HTLV-I) infection.
Results: Five incident and two prevalent infections were detected in the study population. The observed risk of HTLV-I transmission by transfusion was 0.024% (5/20,963) per unit with 95% upper bounds of 0.050%. The risk per cellular component was 0.028% (5/17,623) with 95% upper bounds of 0.060%. Comparison of the five seroconvertors with sets of controls who received an equivalent number of blood components suggested that transfusion of platelets is particularly associated with HTLV-I transmission.
Conclusions: These data suggest that despite similar modes of transmission and some overlap in risk groups, HIV-1 screening is not a satisfactory surrogate for HTLV-I. These results also provide important information about the risk of HTLV-I transmission by transfusion of blood components prior to specific screening of donor units for HTLV-I.

M.B.P.162 PREVALENCE OF HTLV-1 ANTIBODIES IN BLOOD DONORS IN THE NETHERLANDS

Van Der Poel, Cees*; Lelie, N.**; Reesink, H.*; Ehlers, P.**; Bakker, E.**; Huisman, H.**
* Red Cross Blood Bank, Amsterdam, ** Central Laboratory of the Netherlands Red Cross Blood Transfusion Service, Amsterdam, The Netherlands.

Objective. To establish the prevalence of HTLV-1 antibodies in blood donors in the Netherlands.

Methods. Serum samples from regular blood donors (n=20,037) were tested with a commercially available ELISA for HTLV-1 antibodies. Repeatedly ELISA reactive samples were tested for confirmation with commercially available WB strips and ^{125}J-RIPA developed in our institute.

Results.

	n	ELISA reactive initially	repeatedly	Western Blot pos	indet.	^{125}J-RIPA pos	indet.
donors	20,037	49 (0.24%)	26 (0.13%)	1	14	1	10

Only 1 donor was found confirmed positive for HTLV-1 antibodies with p19, p24, p28, p36, gp46 in WB and p24, p28, p40x/gp46 in ^{125}J-RIPA.

Conclusions. The prevalence of HTLV-1 antibodies in blood donors in The Netherlands is low and in the order of 0.005 % .

Transfusions/Dépistage
Transfusions/Tests

M.B.P.163 COMPARISON OF IMMUNOASSAYS FOR EARLY DETECTION OF HIV-1 SEROCONVERTERS

Vellaca, W.; Phillips, S.; Schochetman, G; George, James. Centers for Disease Control, Atlanta, GA, USA.

Objective. To evaluate various immunoassays for their ability to detect early seroconverters to human immunodeficiency virus (HIV) type 1 infection.
Methods. Pre- and post-plasma panels for 12 individuals identified by various immunoassays as having seroconverted (positive Western blots) to HIV-1 were tested by 7 immunoassays employing 5 different technologies. Tests used were Organon Teknika Vironostika enzyme immunoassay (EIA); Serodia Particle Agglutination Test (PA); Chiron Recombinant Immunoassay (RIBA); DuPont Western blot (WB); and three immunofluorescence assays (IFA), Electro-Nucleonics (ENI), Cellular Products (CP), and Fluoronost (FL). Western blots were judged positive, indeterminant or negative by the criteria of the Assoc. of State and Terr. Pub. Health Lab. Directors (ASTPHLD).
Results. Listed are the number of times each method was first or tied with other methods to give a positive result: PA (11/12), EIA (7/12), RIBA (8/12), WB (3/12), CP (3/12), ENI (9/12), FL (6/12).
Conclusions. The PA test was found to be the most sensitive test. The PA test became positive 3-5 days before other methods. Sensitivity of the IFA tests varied among the three kits compared, ENI was the second most sensitive test overall, while CPI was the least sensitive. Western blot detected antibodies to gag proteins at about the same time as the PA became positive but did not meet the ASTPHLD positive criteria in one panel until 20 days after the PA became positive. EIA, RIBA, and FL were similar in their sensitivities.

M.B.P.165 PROGRESSIVE CHANGES WITH TIME IN EXPRESSION OF CARBOHYDRATES ANTIGEN IN PBL OF HIV INFECTED PATIENTS.

GILL[1], M.J., SCHIOZAWA[2], C., KASHIWAGI[2], N., CHURCH[1], D., OHNISHI[2], M., POON[1], M.C., JOHNSON[3], S., ADACHI[2], M. [1]Faculty of Medicine, University of Calgary, Calgary, Canada. [2]Japan Immunoresearch Laboratories, Takasaki, Japan. [3]Foothills Hospital, Calgary, Canada.

We have found in vitro that HIV infection of TALL lymphocytes causes significant expression on the lymphocytes of a carbohydrate determined by the BM-1 monoclonal antibody (J Exp Med, 1988; 167: 323). Patients with AIDS have high levels of BM-1 expression and asymptomatic patients have low level of expression. Over 200 HIV positive patients have been followed prospectively to determine if BM-1 expression correlates with clinical state or prognosis. BM-1 expression above 15% on lymphocytes was associated with a poor clinical state or evolving infection and a low absolute T4 lymphocyte count. Continued high level of BM-1 expression and low T4 counts persisted in patients receiving Zidovudine. BM-1 expression may have some value as a marker of progressive disease and could also be involved in the pathogenesis of cell destruction. A continued evaluation of this cohort would appear merited

M.B.P.167 SCREENING OF BLOOD DONATION WITH EIA COMBINED TEST (COMBI IgG EIA) BY USING SYNTHETIC PEPTIDES TO DETECT ANTI-HIV 1 / ANTI-HIV 2.

Hamerschlak, Nelson*; Carvalho, M. B.*; Misawa, H.*; Cavagnoli, K.*; Guerra C. C. C.* and Szterling, L.*.
*Centro de Hematologia de São Paulo and Hospital Israelita Albert Einstein, São Paulo, Brazil

Objective: to evaluate the behaviour of the EIA test containing synthetic peptides (Pharmacia Combi IgG EIA) for screening blood donation.
Methods: 2503 random samples and 25 anti-HIV + Combi IgG EIA were performed in comparison to ENI EIA test. Western Blot was the confirming test.
Results: 9 random samples (0,36%) out of 2503 ENI + and confirmed by WB were stongly + with Combi IgG EIA; 26 samples (1%) ENI false + were - with Combi IgG EIA; 19 samples ENI true + were in accordance with Combi test while 1 out of 6 false + samples was + with the Combi test.
Conclusion: the Combi IgG EIA proved to be sensible and agreeing when compaired to ENI test.

M.B.P.164 COMPARISON OF NINE HIV-1 SEROCONVERSION DONORS ON SIX HIV-1 ANTIBODY ASSAYS

Susan L. Stramer*; Gibes, J.**; Zemel, E.**; Sachs, K.*; Mathieu, M.*; and Heller, J.S.*.
*Abbott Labs, N. Chicago, IL; **North American Biologicals, Inc., Miami, FL, U.S.A.

Objective. An evaluation of six detection systems for HIV-1 antibody was performed on a total of 49 early seroconversion samples from nine donors.
Methods. Viral and recombinant enzyme immunoassays (Abbott Labs and Cambridge BioScience), and rapid detection assays (Abbott and Cambridge) were evaluated on a panel of 49 HIV-1 seroconversion samples originating from nine donors.
Results. Of the 49 seroconversion samples tested, both recombinant EIAs detected 42 (86%) samples as positive. Abbott Test Pack (recombinant) also detected 42 samples as positive, which was followed by the Abbott modified viral EIA that detected 41 samples as positive. All assays of seroconversion samples progressed from negative to moderately reactive with the exception of the latex agglutination assay. With the latex agglutination assay, samples from one of the nine donors progressed from negative to positive; however, there were no samples detected as positive for two donors and the majority of donors (six) were positive for only the earliest bleeds with subsequent bleeds becoming negative. The samples that were detected as negative in the latex agglutination test for these six donors were positive by all other assays. The results for these six donors on the latex agglutination assay most closely correspond to their anti-HIV IgM reactivities.
Conclusion. Results suggest that the latex agglutination assay appears to have reduced sensitivity compared to the other assays in this evaluation on samples having low levels of IgG typically contained within seroconversion series.

M.B.P.166 PACKED RED BLOOD CELL (PRBC) TRANSFUSION (TX) THERAPY FOR ANEMIA IN PATIENTS WITH AIDS AND ARC: INCIDENCE, ASSOCIATED FACTORS, AND OUTCOME

Jacobson, Mark A, Peiperl, L, Volberding, PA, Porteus, D, Toy, PTCY, Feigal, D. UCSF and SF General Hospital, San Francisco, CA. USA.

Objective. Determine the incidence, associated probable etiologic factors and clinical outcome of PRBC Tx therapy (Rx) in patients with HIV disease.
Methods. We reviewed records of the San Francisco General Hospital (SFGH) Blood Bank and identified 263 likely AIDS and ARC patients (pts) who received 1545 units of PRBC between July 1, 1987, and June 30, 1988. A probability sample of 80 of these pts were randomly selected for detailed chart review. Of this sample, 78/80 (98%) were confirmed to have AIDS (84%) or ARC (14%).
Results. Based on the yearly census of the SFGH AIDS clinic, we estimated a Tx incidence of 0.36 (0.89 PRBC units)/pt/year for pts with AIDS and 0.11 (0.27 PRBC units)/pt/year for those with ARC. Of the 177 Tx's studied in detail, antimicrobial drug therapy, zidovudine therapy, and disseminated M. avium complex (MAC) infection were the sole likely etiologic factors in 20%, 14%, and 12% of the Tx's, respectively. To assess the role of MAC, the 263 Tx'd pts were compared with the 574 pts who had blood submitted to the SFGH Mycobacteriology Laboratory during the same time period. Pts whose blood yielded MAC had a relative risk of 5.2 for Tx-requiring anemia. After 80% of Tx's, the pt returned to home.
Conclusion. Most PRBC Tx's administered to AIDS or ARC pts were clinically appropriate Rx. Applying our incidence data to the US PHS estimates of future AIDS cases, we estimate that in 1992 the expected Tx needs of pts with AIDS and ARC will represent 1-2% of the total PRBC supply in the US.

M.B.P.168 DETECTION OF ANTIBODIES TO HUMAN IMMUNODEFICIENCY VIRUS IN VENOUS AND CAPILLARY WHOLE BLOOD BY LATEX AGGLUTINATION

Celeste Chenet-Monte, K. Mayer*, and C.H. Riggin
Cambridge BioScience Corporation, Worcester, MA, USA, *Fenway Community Health Center, Boston, MA, USA.

Objective. The ability of rapid agglutination test to detect antibodies to human immunodeficiency virus (HIV-1) in capillary and venous whole blood samples was evaluated.
Methods. Recombigen -HIV-1 LA is a five minute latex agglutination (LA) test which uses polystyrene beads coated with recombinant env antigen to detect antibodies to HIV-1. Capillary blood, anticoagulated venous whole blood, and serum samples were collected from 137 high risk patients in a Boston clinic. Pairs of anticoagulated whole blood and serum samples were collected from 57 patients at a hemophilia clinic and 96 donors at a transfusion center. These samples were tested by latex agglutination and the results were compared to those obtained by a licensed enzyme immunoassay with serum. All positive samples were confirmed by Western blot analysis and, in some cases, by radioimmunoprecipitation.
Results. Using whole blood samples at the recommended 1:10 dilution, all 77 confirmed HIV seropositive samples tested were detected by the Recombigen HIV-LA test, (sensitivity=100%). With 213 seronegative samples specificity was 98.1% with whole blood. Agreement between anticoagulated venous whole blood and capillary blood was 100%.
Conclusion. These data show that the 5 minute LA test can be used to detect HIV antibodies in venous and capillary whole blood.

M.B.P.169 IMPACT OF LEUKOCYTE FILTRATION OF DONOR BLOOD ON REDUCTION OF HUMAN IMMUNODEFICIENCY VIRUS-INFECTED CELLS

Rawal,Bhagat*;Busch,M*,**;Radow,R.*;Perkins,H.*,**;Schwadron,R.** and Vyas,G.**
*Irwin Memorial Blood Centers,**Department of Laboratory Medicine,University of California, San Francisco,California, USA.

Objective. To test the hypothesis that removal of leukocytes by filtration of donor blood reduces the load of HIV-infected cells.
Methods. Units of blood from 4 seronegative donors were inoculated in vitro with cell-associated HIV using chronically infected HIV-SF2-HUT78 lymphocytes (2×10^3 - 1.8×10^4 TCIU/ml). Three additional units collected from seropositive donors contained HIV infected cells at 0.041-7.75 TCIU/ml. Units were filtered through 3 different brands of leukocyte removal filters. Lymphocytes were counted by hemocytometer following ficoll-hypaque concentration of blood before and after filtration. HIV infectivity was titrated by determining tissue coculture infective units/ml(TCIU) and/or polymerase chain reaction (PCR) for HIV-DNA.
Results. Filtration resulted in a 99.51% - 99.97% reduction in donor lymphocytes. HIV infectivity in the post-filtered blood from the experimentally inoculated units varied between 0.0 and 1.086 TCIU/ml, representing a reduction from 99.96% to 100%. HIV infectivity was no longer demonstrable by tissue culture methods in post-filtered blood from 2 of the 3 units from seropositive donors; the filtered blood from the third donor contained HIV at 0.053 TCIU/ml. PCR was positive in the 2 filtrates tested indicating a low level of residual cell-associated HIV DNA.
Conclusions. Leukocyte filtration significantly reduced the HIV infectivity of units of infected donor blood. Leukocyte removal by filtration should further minimize the risk of transfusion transmitted infections, especially when used in conjunction with the current donor screening programs.
(Supported by NHLBI grant N01-HL-41631-01).

M.B.P.170 THE ADAPTATION AND EVALUATION OF HIGH PERFORMANCE ELISA ASSAYS FOR DETECTION OF HIV ANTIBODIES IN DRY BLOOD SPOTS.

J. W. D. Kay, T. S. Flowers, J. V. Roman, F. V. Creut, Organon Teknika Corp., Durham, N. C. 27704, U. S. A.

Objective. To demonstrate that a high performance ELISA test, i.e., 100% sensitivity and >99.9% specificity, can be used to detect antibody in whole blood specimens collected in the dry blood spot (DBS) format.
Methods and Results. Sensitivity and specificity panels were prepared in the DBS format. Conditions were developed to elute the specimens from the DBS and test them in a microelisa system such that the system sensitivity and specificity were equivalent to that obtained from the respective plasmas.
The DBS protocol was then field tested with dry blood spots from low risk populations of 2000 normal blood donors. The repeat reactive rate of 0.1% was comparable to the plasma rate on these specimens. The protocol was used with a high risk population of 200 individuals. The repeat reactive rate was 44%. Neonatal blood spots (n=2985) were evaluated from a west coast USA site and gave an initial reactive rate of 0.7% and a repeat reactive rate of 0.1%. Two of the three repeat reactives were verified by immunoblot while the third was classified as indeterminate having detectable reactivity to p66, gp120 and gp160 proteins. In addition, 500 neonatal dry blood spots were evaluated from a midwest USA site and gave initial and repeat reactive rates of 0.0%.
Conclusion. The development of high sensitivity/specificity ELISA systems for detection of antibody in serum and plasma has been essential to the protection of blood supplies. These results indicate that it is possible to adapt high performance ELISA tests to provide comparable antibody detection even if using specimens collected in the dry blood spot format. Such an ELISA test application may be essential for future testing of blood and a most preferable option to get consistency of sample collection for worldwide epidemiological studies.

M.B.P.171 DO REALLY EXIST AUTOANTIBODIES TO RED BLOOD CELLS IN PATIENTS WITH POSITIVE ANTI-HIV SEROLOGY?

Ciaffoni,S.*;Rosta,C.*;Antonello,O.*;Aprili,G.*;Malena,M.**; Luzzati,Roberto**.
*Blood Transfusion Service,Verona;Clinical Infectious Diseases,Verona,Italy.

Objective.Autoantibodies against platelets,granulocytes,lymphocytes have been cleary demonstrated in HIV + patients but not all the authors have found auto antibodies to red blood cells(RBC).We have studied 90 patients with HIV infection for the presence of athypical RBC antibodies.
Methods.Ninety blood samples from 15 AIDS patients,20 with ARC,25 with PGL, 30 symptom-free individuals(SF),were tested for the presence of auto and allo antibodies to RBC by direct antiglobulin test(DAT) and by irregular antibodies screening test.We have also tested 100 hospitalized patients with diseases other than AIDS and 100 healthy blood donors.
Results.No autoantibodies against RBC were found,in fact all DAT were negative.We have found cold agglutinins(CA)in 20 of 90 patients(22%);in 3 of 15 with AIDS(20%);in 7 of 20 with ARC(35%);in 5 of 25 with PGL(20%) and in 5 of SF(16%);all other patients and blood donors were negative.None of these CA reacted at 37°C and none patient has evidence of hemolysis.Serological specificities of CA were 14 anti I; 5 anti i and one anti Pr.
Conclusion.RBC bound immunoglobulins were detected in none of our patients. We think that the presence of CA could be due to HIV or others viruses that act as direct inducers of autoimmunity.

M.B.P.172 EVALUATION OF SERODIA PARTICLE AGGLUTINATION ASSAY FOR ANTIBODY TO HIV

Busch,Michael*;Bueno,C*and Cordell,R.*.
*Irwin Memorial Blood Centers, San Francisco, California, USA.

Objective. To compare the specificity and sensitivity of the Serodia passive particle agglutination anti-HIV assay (PA) with USA-licensed viral-lysate enzyme immunoassays (EIA) and Western blot (WB).
Methods. Specificity was assessed by testing 2,031 random blood donor specimens, 70 specimens from persons with diseases other than HIV infection, as well as 66 EIA(+)/WB(-) and 51 EIA(+)/WB-indeterminate specimens collected from donors shown by followup not to be infected with HIV. Sensitivity was evaluated by testing 51 previously identified WB(+) blood donor specimens, as well as by comparative end-point titration of 9 WB(+) donor specimens.
Results. Only 3/2031 (0.14%) routine donor specimens were initially reactive (non-repeatable) by PA, yielding a sensitivity of 99.86%. None of the 70 specimens containing potential cross reactive antibodies was PA(+). Of the previously detected EIA(+) donor specimens, 0/66 WB(-) and 2/51 WB-indeterminate were PA (+). All 51 WB(+) donor specimens were PA(+) (100% sensitivity); the PA assay was 4 to 16,384-fold more sensitive by titration.
Conclusion. The Serodia PA assay appears to be more sensitive and is clearly more specific than currently avaliable viral-lysate EIAs.

M.B.P.173 SENSITIVITY AND SELECTIVITY OF HTLV-I IMMUNOASSAYS.

Lipka, James J.; Parker, J.L. and Foung, S.K.H. Stanford University Blood Bank, Palo Alto, CA, USA.

Objective. Determine the sensitivity and selectivity of Abbott, Cellular Products (CPI) and DuPont HTLV-I antibody screening ELISAs.
Methods. A panel of 73 HTLV-I/II positive sera was used to determine the sensitivity of FDA approved ELISAs. Selectivity was measured in a blood donor population, with a cutoff adequate to obtain 100% sensitivity.
Conclusions. The CPI assay is 100% sensitive, while the Abbott and DuPont ELISAs cutoffs must be redefined. The redefined Abbott test demonstrates substantially better selectivity than either the CPI or DuPont tests.
Results. The positive sera panel included 52 IVDAs, 1 ATL, 1 TSP, 9 blood donors, 3 clinical (symptoms unknown) and 7 Japanese samples. Seropositive is defined as p19 and p24 or p24, p36 and gp46 by Western blot or p24 Western blot and gp68 by RIPA. C.O.r = signal/C.O. of the weakest positive:

	RR	False Negative	C.O.r
Abbott	67/69	2/69 (2.9%)	0.856
CPI	73/73	0/73 (0.0%)	1.055
DuPont	61/69	8/69 (11.6%)	0.786

Random blood donors were tested and evaluated with both the manufacturers' recommended cutoff (C.O.) and a redefined cutoff (C.O.r). Selectivities:

		C.O.		C.O.r	
	N	RR	False Pos.	RR	False Pos.
Abbott	2,618	2	1 (0.04%)	2	1 (0.04%)
CPI	289	6	6 (2.0 %)	6	6 (2.0 %)
DuPont	2,523	20	19 (0.75)	36	35 (1.39%)

M.B.P.174 USE OF THREE RECOMBINANT ASSAYS TO TEST BLOOD DONOR SAMPLES WITH WESTERN BLOT (WB) INDETERMINATE PATTERNS

Scalia, Vito*; Buchner, B.K.*; Reeves, J.P.*; Sabourin, L.*; and Gill, P.*. *The Canadian Red Cross Society, National Reference Laboratory, Virology, Ottawa, Canada.

Objective - To further attempt to clarify the significance of WB indeterminate blood donor samples by testing with recombinant assays.
Methods - All donor samples were screened initially for the presence of anti-HIV by Abbott, Genetic Systems or DuPont EIA. Any sample found to be reactive was subjected to the DuPont WB. Donor samples with a WB indeterminate result (Nov. 1985 to Nov. 1988) were tested with three EIA recombinant assays: Recombigen® (p24 / gp41 and 120), [illegible]™ (p24) and [illegible]™ (p24 / gp160).
Results - A total of 6592 WB indeterminate donor samples were tested which included approximately 45% from returning donors. Of these, 60% retained a WB indeterminate pattern and none seroconverted to WB positive. All samples (n=6592) were tested by Recombigen®. Of these, 1120 were tested by [illegible]™ (p24) and 1487 by [illegible]™ (p24 / gp160). Results of the samples tested were as follows:

[illegible]	[illegible]		[illegible]		[illegible]	
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]

Conclusion - The Recombigen assay (the more sensitive and specific of the three recombinant protein assays used in this study) helps clarify the negative status of the majority of WB indeterminate donors with respect to HIV in this low risk population. Conversely, a reactive Recombigen result indicates the need for follow-up of a donor who is potentially in the process of seroconverting.

M.B.P.175 RECURRENCE RATE FOR BUCCAL CANDIDOSIS AND ITS RELATIONSHIP TO T4 COUNT AND P24 ANTIGEN.

DON.E.SMITH. M.ALLAN. J.MIGLEY. B.G.GAZZARD.
ST.STEPHENS HOSPITAL, FULHAM ROAD, LONDON, ENGLAND.

OBJECTIVE: To assess time to recurrence of buccal candidosis after successful treatment and its relationship to T4 count and HIV P24 Antigen.
METHODS: 100 HIV positive patients with confirmed buccal or buccal and oesophageal candidosis received a 4 week course of either Itraconazole 200mgs O.D. or Ketoconazole 200mgs B.D. Successful treatment was assessed as clinical and mycological clearance. Patients were followed for a further 3 months with regular clinical and mycological assessments in conjunction with T4 counts and P24 Antigen levels monitored each visit.

RESULTS:

	RELAPSE			
	WITHIN 1 MTH.	WITHIN 2 MTHS.	WITHIN 3 MTHS.	CLEAR AT 3 MTHS.
ITRACONAZOLE:	19 (56%)	25 (74%)	27 (80%)	6 (18%)
KETOCONAZOLE:	22 (63%)	27 (77%)	28 (80%)	7 (20%)
TOTAL :	41 (60%)	52 (76%)	55 (80%)	13 (20%)

T4 (mm^3);	NO.	MEAN.
AT ENTRY:	43	153
RELAPSE:	21	104
NON-RELAPSE:	30	124

P24 Ag(u/ml);	NO.	NEG.	POS.	MEAN.
AT ENTRY:		58	37	111
RELAPSE:		38	27	124
NON-RELAPSE:		42	21	53

CONCLUSION: 80% of HIV patients with oral candida have a clinical and mycological relapse within 3 months of a successfully treated episode. T4 levels and P24 Antigen levels are not useful in predicting relapse.

M.B.P.176 PROBABILITY OF DEVELOPING AIDS IN HIV-INFECTED PATIENTS WITH MUCOCUTANEOUS LESIONS.

Podzamczer,Daniel; Bolao,F.; Pagerols,X.; Pallares,R.;Gudiol, F. Hospital de Bellvitge. University of Barcelona. Barcelona..Spain.

Objective. To study the role of mucocutaneous lesions (MCL) as a predictor of AIDS in HIV-infected pts.
Patients and methods. Two hundred thirty nine HIV-positive pts without AIDS were followed during a mean of 11 months (1-41). The follow up period began when HIV antibodies were detected in non MCL-group or when MCL were observed in MCL-group, and finished with last visit made before December 88 or with the development of AIDS. MCL were diagnosed using clinical, histological and /or microbiological criteria.
Results. Eighty nine pts (37%) had one or more MCL: 64/190 (34%) drug addicts 16/26 (61%) homosexuals, 4/15 (27%) heterosexuals, 3 addicts and homosexuals and 2 of unknown risk groups. Three of 150 (2%) pts without MCL and 13 of 89 with MCL developed AIDS. MCL were oral thrush(4 pts), hairy leukoplakia(4), seborrheic dermatitis(3), herpes zoster(3) and simplex(3), folliculitis(1) and oral ulcers(1).
The Kaplan Meier survival method shows a percentage of free-AIDS pts at 20 months of 45%(95% confidence interval 36 to 54) in those with MCL comparing with 98%(95% confidence interval 82 to 114) in those without MCL.($p < 0.0001$).
Conclusion. Our findings show that the presence of MCL in HIV-positive pts may indicate an increased risk of developing AIDS in the following months, although some of these lesions may have a different role as a predictor of AIDS. These pts may be considered for antiretroviral therapy.

M.B.P.177 MYCOBACTERIAL SKIN INFECTION IN AIDS

Lomvardias, Stylianos and Vaidya, K.P.
Dept. of Pathology, Woodhull Medical and Mental Health Center
Brooklyn, New York 11206, USA.

Cutaneous mycobacterial infection is a rare complication of AIDS. We describe two young intravenous drug addicts with oral candidiasis and mycobacterial ulcers and abscesses.

Case 1. A 33 year old black woman presented with fever, chills, diffuse lymphadenopathy and abscesses in the axilla and adjacent chest wall which required repeated drainage and debridement. PPD and HIV antibody tests were refused. The patient developed marked respiratory distress and chest Xray suggested septic emboli. Dermis and subcutaneous tissue showed coagulative necrosis, and numerous acid-fast bacilli consistent with M. tuberculosis (Mtb) but no granulomata or multinucleated giant cells. The organism was grown in urine but not in sputum or blood.
Case 2. A 33 year old Hispanic man with history of hemoptysis required drainage of a large abscess of the forearm and debridement of a 4x3cm ulcer of the anterior chest wall. Necrotizing granulomata in the dermis and in subcutaneous fat of chest wall contained few acid fast bacilli resembling Mtb. Chest Xray did not suggest tuberculosis but pneumonic infiltrates were seen. Mtb was recovered in sputum culture. The patient developed respiratory distress and coma, and died on the ninth day.

Conclusion. Mycobacterial infection must be considered in the differential diagnosis of skin ulcers and abscesses in intravenous drug addicts, especially in the presence of other manifestations of AIDS, and appropriate bacteriologic studies must be performed.

M.B.P.178 HYPERKERATOTIC DISSEMINATED HERPES ZOSTER IN PRETERMINAL AIDS

Alan M. Solinger,M.D.; W.B.Hoppenjans,M.D.; R.Orme,M.D.; M.Bibler,M.D. / University of Cincinnati Medical Center
Cincinnati, Ohio; U.S.A.

Unusual infectious diseases as well as unusual presentations of common infectious diseases have frequently been reported in patients with AIDS.

We report two cases of an unusual presentation of a verrucous hyperkeratotic type of disseminated Herpes zoster in adult males with AIDS. We feel that this presentation represents an extreme of the V-Z infection not previously reported.

These hyperkeratotic, crusted skin nodules developed after the generalization of typical herpes zoster and progressed despite oral and intravenous acyclovir. Both patients had secondary Candida albicans infections of the crusted lesions and evidence of atypical Mycobacterial infection. One patient had cultures of blood and skin positive for Mycobacterium avium-intracellulare. Of interest, both patients ultimately developed a vacuolar myelopathy (confirmed by clinical presentation and EMG).

We believe that our patients represent a presentation of disseminated Herpes zoster unique to the AIDS patient that will be encountered more frequently in the future. The unrelenting, disfiguring nature of this disease as well as its apparent unresponsiveness to Acyclovir is of particular concern. One of the patients succumbed to his myelopathy while the other developed it during a worsening of his skin lesions. This clinical picture may be a harbinger of a rapidly fatal outcome.

M.B.P.179 VARICELLE ET INFECTION A HIV.

Perronne, Christian; Lazanas M.; Leport C.; Salmon D.; Bricaire F. et Vildé J.L.
Hôpital Claude-Bernard, 75018 Paris, France.

Objectif : Etude rétrospective de la varicelle chez 15 malades infectés par le HIV (HIV+) entre 1981 et 1988.
Méthodes : Parmi 421 malades HIV+ hospitalisés, 15 (3,5%) ont fait une varicelle. Le diagnostic a été clinique. Une culture du virus varicelle-zona (VZV) ou une biopsie cutanée a été réalisée chez 3 malades ayant une éruption atypique.
Résultats : Il y avait 12 adultes d'âge moyen 32 ans (18 à 70 ans) et 3 enfants d'âge moyen 3 ans, 5 dans les groupes II ou III des CDC, 2 dans le groupe IV-C2, et 8 SIDA. Un malade a eu une 1ère varicelle 31 mois et un zona 9 mois auparavant. Un contage varicelleux a été retrouvé chez 6 malades. Un malade, HIV+ asymptomatique, a fait une varicelle fulminante et est décédé d'une coagulation intravasculaire disséminée malgré l'aciclovir. Trois SIDA ont fait une éruption atypique avec une dizaine d'ulcérations chroniques contenant le VZV. Un malade a été traité par vidarabine et 11 par aciclovir i.v. Un SIDA a fait 3 rechutes de varicelle avec des lésions atypiques malgré l'aciclovir.
Conclusion : La varicelle des sujets HIV+ peut être récurrente et se manifester par des lésions atypiques. Le risque de formes mortelles justifie l'aciclovir i.v.

M.B.P.180 "NON-INFECTIOUS" DERMATOSES: CORRELATION WITH CD 4^+ - T-LYMPHOCYTES AND STAGE OF HIV-INFECTION

Ochsendorf, Falk, Schöfer, H. and Milbradt, R.
Klinikum J.W.Goethe-Universität,Dept.of Dermatology,Frankfurt,FRG.

Objective. To investigate whether cutaneous diseases, regarded as "non-infectious" up to now, allow a clinical evaluation of the stage of HIV-infection.-
Methods. Over a 4-years-period, 267 HIV-infected patients (254 male, 13 female) were examined 4 times on an average. At first manifestation of a skin disorder, stage of HIV-infection and CD 4-counts were recorded.-
Results. On entry of the study the mean CD 4-count was 407/µl.

	SLS	LAS	ARC	AIDS	all	CD4/µl
	%(n=18)	%(n=86)	%(n=76)	%(n=87)	%(n=267)	mean
Seb.dermatit.	17 (3)	21 (18)	30 (23)	40 (34)	29 (78)	345
Pruritus	6 (1)	20 (17)	34 (26)	32 (28)	27 (72)	372
Xerodermia	11 (2)	13 (11)	26 (20)	34 (30)	24 (63)	316
Kaposi-Sarkoma	- -	- -	- -	52 (45)	17 (45)	224

(SLS=asymptomatic stage; Seb.dermatit.=Seborrheic dermatitis)
13 patients (4,9%) had lesions typical of psoriasis vulgaris. On progression of the disease in 6/9 cases CD-4 counts were lower than 200/µl.
Conclusion. "Non-opportunistic" dermatoses were more frequent and severe in advanced stages of HIV-infection and increased with decreasing CD 4-counts. So they were a reliable clinical marker of cellular immunodeficiency indicating the risk of the individual for severe opportunistic infections.

M.B.P.181 MANIFESTATIONS CUTANEES ET VENEREOLOGIQUES CHEZ LES MALADES INFECTES PAR LE VIH EN GUYANE FRANCAISE

R.PRADINAUD*, D. SAINTE-MARIE
*Centre Hospitalier de Cayenne, Cayenne, Guyanne Française.

130 cas de S.I.D.A. ont été répertoriés de 1982 à 1988 dans une population de moins de 100.000 habitants incluant 20.000 immigrants haïtiens et un petit nombre de prostituées de Santo-Domingo.

Les principaux modes de transmission du VIH sont de type hétérosexuel (87,69%), et maternofoetal (10,75%).

Un seul cas a été constaté chez un homosexuel (0,75%) et il était porteur d'un sarcome de Kaposi. Un autre cas a été constaté chez un homme hétérosexuel : 2 cas sur 130 est un taux très bas pour le SARCOME DE KAPOSI.

L'infection muqueuse la plus fréquemment rencontrée est la CANDIDOSE et l'infection cutanée le PRURIGO : cette manifestation cutanée est le meilleur signe d'orientation vers le test sérologique et ne doit pas être confondue avec la gâle chez l'enfant.

L'HERPES SIMPLEX, le ZONA et les infections à PAPILLOMA VIRUS ont une incidence élevée, une évolution sévère, mais l'herpès et le zona peuvent être traités par l'Acyclovir.

La TRICHOMONASE est fréquemment observée et son rôle pour la transmission du VIH de la femme à l'homme nous apparait très important, le parasite ouvrant la muqueuse vaginale et la partie prépuciale du pénis.

3 cas de DONOVANOSE doivent être mentionnés en raison de l'épidémiologie par contacts sexuels anaux ; la faible agressivité de *Calymmatobacterium granulomatis* nécessite un défaut immunologique cutané pour être réellement pathogène. Une LEPRE LEPROMATEUSE récurrente a aussi été observée.

M.B.P.182 DERMATOLOGICAL MANIFESTATIONS AND HIV INFECTION

Abreu, E.A.V.; Quinhões, Eleonora Pati; Rachid de Lacerda, M.C.; Serra, M. S.; Sion, F.S.; Morais de Sá, C.A.
Gaffrée & Guinle University Hospital - University of Rio de Janeiro (UNI-RIO) - Brazil.

Objective: To analyse all dermatological manifestations among 409 HIV infected patients.

Methods: We made a retrospective study of all mucocutaneous findings among patients attending our "AIDS" Clinic from November 1983 to August 1988. HIV infection was confirmed by ELISA, Indirect Immunofluorescence and/or Western blot techniques. All mucocutaneous lesions were confirmed by biopsy and/or culture when needed. Patients were evaluated for age, sex, risk group, stage of infection and types of lesions. We did not evaluate treatment or response to treatment.

Results: We found mucocutaneous manifestations in 227 patients (55,5%), 212 male (93,39%), 182 homo/bisexuals (80.17%). Most of the patients presented more than one type of lesion.

TYPE OF LESION	PATIENTS	
	N	%
Kaposi's sarcoma	48	21.15
Oral candidiasis	91	40.10
Other fungal	28	12.33
Viral	65	28.63
Bacterial	31	13.66
Seborrheic dermatitis	56	24.67
Others	64	28.19

Conclusions:

1) Dermatological manifestations are common among our HIV infected patients.
2) It is possible to make a suspicious diagnosis of HIV infection observing the skin.
3) Seborrheic dermatitis, Kaposi's sarcoma and oral Candidiasis were the most common mucocutaneous manifestations.

M.B.P.183 MANIFESTATIONS CUTANEO-MUQUEUSES DU SIDA AFRICAIN

Coll Awa Marie* ; Ball M.D.**; Benga E.* ; Faty/Ndiaye C.*** ; Faye/Ndao M.A.* ; Feller-Dansokho E.* et al*.
C.H.U de Dakar, *Service des Maladies infectieuses; **Service de Dermatologie; ***Institut d'Odonto-stomatologie de Dakar, Dakar, Sénégal.

Objectifs. Décrire les manifestations cutanéo-muqueuses observées chez le Noir africain atteint de SIDA (HIV1 - HIV2).

Méthodes. Etude rétrospective des dossiers de malades hospitalisés dans le Service de Pathologie Infectieuse. Leur suivi a été fait en collaboration avec un dermatologue du C.H.U. Une iconographie a été établie.

Résultats. Sur 73 malades atteints de SIDA, 61 ont présenté des manifestations cutanéo-muqueuses dont 19,6% cutanées, 16,4% muqueuses et 70% associées. Les candidoses bucco-pharyngées sont les plus fréquemment observées (70,49%). Le sarcome de Kaposi est rare (4,9%). Les autres manifestations sont retrouvées à des taux variables.

Conclusion. Dans notre étude, nous confirmons la rareté du Kaposi SIDA en Afrique mais retrouvons les manifestations classiquement décrites.

M.B.P.184 PRIMARY HIV-1 INFECTION WITH VIRUS DEMONSTRATED IN HISTOCYTES OF SKIN RASH

Wallace, Joyce I.*, **; Oliver, J.**; and Beatrice, S.***; *Saint Vincent's Hospital and Medical Center, **Foundation for Research on Sexually Transmitted Diseases, New York, NY, USA and ***New York City Department of Health, New York, NY, USA.

Objective. To describe a severe case of primary HIV-1 infection.

Methods. The patient is a 22 year old homosexual male who came to New York City from Detroit, Michigan in late June 1988. Upon arriving, he had "unsafe" sex with an older homosexual male for several weeks. Approximately 2 weeks later, he had onset of symptoms including headache, neck pain, profound weakness, and aversion to light and sound, with subsequent development of a bright red skin rash on the thighs and volar surfaces of the arms, demonstrating Koebner's phenomenon. Sera were collected within 2 days of onset of symptoms, and repeat sera and biopsy of the skin rash taken 2 and 3 weeks later.

Results. The headache persisted 9 days, while the skin rash faded gradually over 5 weeks. The initial sera tested negative for antibodies by both ELISA and Western Blot. The repeat sera taken 16 days later was positive for antibidies by both ELISA and Western Blot. Both the initial and repeat sera were negative by the HIV p24 core antigen ELISA test. The H&E skin biopsy showed a leukocytoclastic vasculitis. Electron micrograph showed HIV-like virus particles within the cytoplasm of the histiocyte. White blood counts were as low as 3,000, and at the time of the biopsy, T_4 cell count was 656, and T_8 count was 815.

Conclusion. Primary HIV-1 infection may be severe with symptoms lasting a month. Presence of a skin rash with a mono-like illness should indicate the need for HIV testing in order to make an early diagnosis, creating the opportunity of beginning antiviral therapy to possibly delay progression of the disease.

M.B.P.185 DERMATOLOGICAL MANIFESTATIONS RELATED TO AIDS IN CENTRAL AFRICA.

K. Koyada#, L. Belec##, B. Di Costanzo#, A.J. Georges##, J. Testa##, M.D. Vohito#
National Hospital Center, BP 943, Bangui, Central African Republic;
Pasteur Institute, BP 923, Bangui, Central African Republic.

Objective. To describe and evaluate the frequency of dermatological manifestations in African patients with AIDS.

Methods. One hundred and ten African patients at the National Hospital Center, Bangui, were chosen according to the WHO/Bangui clinical definition of AIDS and were confirmed to be HIV1 positive by Western blot. Patients were given dermatological examination. Kaposi's sarcomas were confirmed by biopsy, and mycosis by fungal culture.

Results. Pruritic lesions were the most frequent symptom in 57/110 patients, associated in 26/57 cases with specific dermatosis. Generalized pruritic eruption with prurigo was seen in 25/57 cases. Kaposi's sarcomas (nodular and papular varieties mainly) in 14/110 patients. The leading viral infection was Herpes zoster (9%) with atypical course (herpes zoster duplex or generalized herpes zoster). Six patients showed mucocutaneous *Herpes simplex* infection. Oral candidiasis was found in 26/110 AIDS patients while 25/110 showed dermatophytic dermatosis.
